AND WILLIAM CURRY, JUN. & CO. DUBLIN.

MDCCCXXVII.

ENCYCLOPÆDIA EDINENSIS.

Brechin.

BRECHIN, a borough town in Angus-shire, in Scotland, which is finely situated on the declivity of the northern bank of the river Southesk, and is eight miles west from Montrose harbour, from whence the tide approaches it within two miles. It consists of one large and several smaller streets, and the population in 1811 was stated at 5559. The manufacture of Osnaburghs and sail-cloth, and the spinning of flax by machinery, with an extensive brewery for beer and porter, which produced 20,000 barrels annually, for home consumpt and exportation, furnish the chief employment to the inhabitants.

Brechin was founded by David I. about the year 1150, and it was a rich bishopric before the reformation. The cathedral, a Gothic structure, supported by twelve pillars, is in part ruinous, occasioned by the ungovernable rage of the reformers, and part of it serves as the parish church, being commodiously fitted up for that purpose; it has an elegant steeple, 120 feet high, in the form of a square tower, with battlements on the top. Contiguous to this stands a remarkable round tower, which is an object of attention to strangers. It is 103 feet high, consisting of 60 regular courses of hewn stone, placed in a circular manner, and tapering towards the top, and surmounted by an octagonal spire. It is furnished with four windows facing the cardinal points, and other four in the spire placed alternately on the sides, and resting on the top of the tower. Near the bottom are two arches, one within the other; on the top of the outermost is seen a crucifixion; between the mouldings of the outermost and inner, a figure of the Virgin Mary and of St John; and on each corner of the bottom of the arch, figures of certain beasts; the whole is finished with exquisite workmanship. Antiquaries have been at a loss to determine the original design for which this kind of tower, of which there is only another in Scotland, at Abernethy, has been constructed.

Of the old castle of Brechin, which was situated on the south side of the town, no trace remains; it stood a desperate siege in 1303, but was compelled to surrender to the English under Edward III. when the brave governor, Sir Thomas Maule, was slain by a stone thrown from an engine. A noble mansion is now built on the site of the castle, belonging to the family of Panmure.

In 1647 this town was greatly distressed by the plague, which carried off 600 inhabitants in the course of one month.

Brecknockshire || Breda.

BRECKNOCKSHIRE, or BRECON, a county of South Wales, having for its boundaries Radnor, Cardigan, and Caermarthen on the north and west, Hereford, Monmouth, and Glamorgan shires on the east and south; is about 35 miles in length and 30 in breadth, and includes a superficial extent of more than 500,000 acres, of which nearly one half is under culture. This county presents great variety of romantic scenery in its lofty mountains, rich vales, and extensive woods. The principal rivers are the Usk, the Wye, and the Yrvon, the picturesque and sublime beauties of whose banks, particularly of the Wye, have often enlivened the descriptions of the tourist. Brecknock Beacon, supposed to be the loftiest mountain in South Wales, is in this county. A lake, about two miles from the town of Brecknock, is two miles long, and nearly of the same breadth, and abounds with otters, tench, perch, and eels.

The population of this county, which in 1801 was estimated at 31,633, had increased, in 1811, to 34,750. It is divided into six hundreds, and 62 parishes. Beside those employed in the labours of agriculture, many of the inhabitants are occupied in the manufacture of woollen stuffs and stockings. The remains of pavements, and of a bath near the town of Brecknock, shew that it was once occupied by the Romans.

BRECKNOCK, or BRECON, the capital of the county of the same name in South Wales, stands on a romantic spot at the confluence of the rivers Hondey and Usk. The ruins of strong towers, of religious houses, and of walls with which it was surrounded, indicate its antiquity and former importance; and fortifications, pillars, bricks, and the occasional discovery of coins in the town and vicinity, afford ample proof of its occupation by the Romans. A tower of the ancient castle is employed as an armoury, and contains 15,000 stand of arms. The population, in 1801, amounted to 2576, and had increased, in 1811, to 3196. Woollen cloths and cotton stockings are the only manufactures. Brecon is 168 miles distant from London.

BREDA, the capital of Dutch Brabant, stands in a marshy country, at the junction of the rivers

Aa and Merck; is strongly fortified, and surrounded with a wall and ditch; and the neighbouring territory can be flooded with water to prevent the approach of a hostile army. The city is of a triangular form; a gate built of brick is erected at each angle, and the ramparts are adorned with rows of elm-trees. The principal buildings are the castle, a large square edifice; the great church, a noble structure, remarkable for its fine spire of 362 feet in height; and the mausoleum of Engelbert Count Nassau, which is enriched with inscriptions and statues. The population is estimated at 10,000; and the manufacture of woollen stuffs, in times undisturbed by the calamities of war, with which Breda has been often visited, has prospered.

Breda was the scene of a severe struggle between Spain and the United Provinces in the 16th century. Reduced in 1567 by the duke of Alva, it was delivered up ten years afterwards to the States-General; and in 1590 was regained by Prince Maurice, who found means to introduce sixty Dutch soldiers, concealed under the cargo of a small vessel, and by them he was admitted into the place during the night. But the most memorable siege happened in 1625, when it was invested by the Spanish general, Spinola, by an army of 50,000 men, and defended by a small garrison of 7000 infantry and a few troops of cavalry, composed of French, Dutch, and English; and after a blockade of ten months, in which the besiegers and besieged sustained all the calamities of disease and famine, and lost about two-thirds of their number, surrendered on very honourable and advantageous terms; and the feeble remains of the garrison were treated with great kindness and generosity on account of their bravery. It was recovered in 1637 by Henry prince of Orange, after a siege of four months; and in 1667, Breda was the seat of the famous conference between the commissioners of France, England, Denmark, and Holland, which terminated in a general peace, and hence called *the peace of Breda*. The calamities of war again visited Breda in the time of the French revolution, and during that eventful period it acknowledged the authority of different masters. Breda is twenty-two miles S.E. from Rotterdam, and forty-six miles south from Amsterdam.

BREMEN, the capital of a duchy of the same name in Germany, and subject to the king of Great Britain as elector of Brunswick, stands on the banks of the Weser, and is divided by that river into two parts, which are denominated the old and the new town, between which a commodious communication is established by means of several bridges. On one of the bridges machinery is erected to raise water for the supply of the town. The town-hall, loaded with a profusion of ornaments, the exchange a modern edifice, the arsenal, the college, and the Lutheran church, are the chief buildings. The houses are well built, and the streets are spacious and clean, excepting in the old town, where they are narrow, and the buildings are in a more antiquated and less commodious form. Bremen is furnished with several philosophical and literary institutions; and the observatory is under the direction of the celebrated astronomer Olbers, the discoverer of the planets Pallas and Vesta.

The population is stated at 40,000; and various kinds of cloth, as linen, Osnaburghs, and printed calicoes, stockings, glass, starch, and strong-beer, for which last Bremen has been long famous, employ the industry and ingenuity of the inhabitants. The whale and salmon fishery are also successfully prosecuted; the trade in wines with France is considerable; the exports in iron, flax, and linen to England, Spain, and Portugal, are extensive; and the commercial intercourse with America is important. Bremen is 48 miles from Zell, and the same distance from Hamburgh.

BRENTFORD, a market-town of Middlesex in England, stands on the north bank of the Thames, is traversed by the river Brent, from which it derives its name, and is famous as the place of election for the members of parliament for the county, when an unusual concourse of persons from the metropolis are drawn to this busy and interesting scene. The population is about 2000; and malting, distilling, brick-making, and the manufacture of earthenware, give employment to many of the inhabitants. To the eastward of Brentford, and on the opposite side of the Thames, are the royal palace and splendid gardens of Kew; and at no great distance to the westward is Sion-house, formerly a rich and celebrated nunnery, and one of the first which was suppressed by Henry VIII. and now the princely residence of the duke of Northumberland. Brentford is seven miles west from London.

BRENTWOOD, or BURNTWOOD, a town of Essex in England, stands on an elevated situation on the road from London to Colchester and Harwich, includes about a thousand inhabitants, and is 18 miles from London.

BRESCIA, an ancient city of Italy, is situated at the foot of a range of mountains on the river Garza, in a plain beautified with verdure, and watered by numerous streams; it is about a league in circumference, surrounded by walls, and defended by a castle. The streets are elegant, and there are several squares, one of which is surrounded with piazzas, and has the town-house in the centre. Nineteen parish churches, thirty convents, a general hospital, a lyceum, some charitable houses, a palace of justice, which is a most splendid edifice, and a cathedral, are its principal buildings.

The population is about 42,000, and the inhabitants, who are very ingenious and industrious, are employed in the manufacture of pistol and musket-barrels, swords, knives, &c. and the working of iron-mines in the vicinity. Copper, jasper, alabaster, touchstones, and a stone which resists fire, of which they form vessels, are found in the vallies and suburbs, and converted into use. They likewise make millstones of different kinds, and have a process of manufacturing lintseed and grape-stone oil. The fisheries are valuable; and gold, as well as fish, is found in the rivers Adige and Oglio. The trade in linen and woollen cloth, in silk, flax, cheese, and iron, is extensive and lucrative.

The territories of Brescia are fertile and abundant in pasturage, so that a crop of flax or millet is not unfrequently raised after one of wheat in the same year.

The cows, from whose milk a large proportion of the celebrated Parmesan cheese is made by the inhabitants around Lodi, are fed in the Brescian territories during the winter season. A sweet wine, called *santo*, which is of a rich yellow colour, is made in the vicinity of Brescia. The distance of Brescia from Mantua is 32 miles, and from Milan 44 miles.

BRESLAU, one of the largest cities of Germany, and capital of Prussian Silesia, is situated on the south side of the Oder, and occupies an extent of two German miles. It contains many commodious streets, and several squares, the houses of which are about five stories high. Of the public edifices, the churches, the hotel de Ville, the college of the Jesuits, the academy, the exchange, the customhouse, the bishop's palace, and a monument erected to General Count Tauenzien, the governor, who commanded during the siege of 1760, the botanical garden, an anatomical theatre, two armouries, a mint, and several libraries, are the principal; and the walks and gardens in the neighbourhood are enumerated among the beauties of the place.

The population is said to exceed 60,000, of which many are French, Bohemians, and other foreigners, and a vast number of Jews. The principal manufactures are iron wares, broad cloths, and other woollen stuffs, silk stuffs, paper, gunpowder, needles, hats, stockings, leather, and calicoes. Besides there are numerous tanners, dyers, and furriers, to whom the Ohlau affords water to facilitate their operations.

Breslau is the centre of the trade of Silesia, has commercial intercourse with Hamburgh through the canal, and with the north of Germany and the Baltic; and exports chiefly the linens of Silesia, flax, thread, wool, fine cloths, and madder.

The imports from the other parts of Germany, from Spain, Italy, and Holland, consist of the various productions of those countries, which are consumed in the town or the surrounding territory.

The land in the neighbourhood is level, and, excepting near the rivers, affords excellent corn; its pastures are rich, abounding with sheep and cattle, and the cows are of a large size. Breslau is 35 German miles from Berlin, 44 from Leipsic, and 74 from Hamburgh.

BREST, a sea-port town in the department of Finisterre in France, situated on a hill on the north of the bay of that name, is divided into two parts, the Cote du Brest and the Cote de Recouvrance, which communicate by boats; and has two parish churches, a governor, a board of admiralty, and a marine seminary. It is chiefly remarkable for its famous road and harbour, capable of containing 500 ships of war in good anchorage, and its barracks, magazines, rope and sail-cloth manufactories, extensive arsenal, dock-yard, forges, and foundery. The entrance to the harbour, which is narrow, is guarded by a castle next the sea, and the town is defended by a ditch and fortifications on the land side.

The population of Brest is 26,000; the trade in wines and brandy, and the fishery, are considerable; and two fairs are annually kept, where cattle, skins, and various merchandise are sold. Brest is 125 leagues distant from Paris.

BRETON, Cape, an island lying near the east coast of North America, between 45° and 47° north latitude, and 50° and 60° west longitude from London, which is separated from Nova Scotia by a small passage called the Gut of Causo, about 100 miles in length and six in breadth, and having the appearance of a cluster of islands. It was discovered about the year 1500 by the Normans and Bretons, and is improperly called Cape Breton, having been supposed to be a part of the continent. The French possessed themselves of it in 1713, and erected Fort Dauphin, which they abandoned from the harbour being of difficult access, and built Fort Louisbourg at an immense expence, where the harbour affords good anchorage.

The climate is cold, and the soil marshy; yet, on the south of the island, abundance of corn, hemp, and flax are cultivated. The inhabitants have chiefly devoted their attention to the fishery, which, while the French possessed the island, was worth a million sterling.

In 1745 the British attacked this island with the assistance of 6000 American troops, and succeeded in procuring a surrender. By the treaty of Aix-la-Chapelle it was restored to the French; but was reattacked in 1758. The French made a vigorous resistance; and having sustained severe loss, several of their ships and frigates being destroyed, were obliged to yield to the intrepid valour of the besiegers. It was confirmed to Great Britain in 1763, since which time the fortifications of Louisbourg have been destroyed.

The possession of Cape Breton is of great value to Great Britain, by securing the fisheries on its coasts from intruders; by the mines of iron and coal, which may be easily wrought to advantage; and by its forests of good hard timber.

BRETAGNE, or Britany, a large province of France, which, in the new division of that kingdom since the revolution, forms several departments. It is bounded on the north, west, and south by the sea, and on the east by Maine and Anjou; enjoys a temperate climate, and possesses great variety of soil. Some parts of it are clothed with woods; excellent crops of wheat, hemp, and flax are raised; and the more elevated districts afford good pasture to numerous herds of cattle. Fruits are abundant; cyder, it is said, is the common drink of the inhabitants; game and fish are plentiful. Mines of iron, lead, and coal have been wrought; and the natives of the sea-coast have been long famous as skilful and hardy seamen.

BREWING.

Introduction.

BREWING is usually defined the art of making malt liquors; but as these liquors differ from wines in little more than the nature of the materials from which they are prepared, the term may not improperly be extended to include the making of all vinous or fermented liquors; and in this sense it is employed in the present Treatise, in which it is proposed to exhibit the principles and describe the practice, according to the most approved methods, of making ale, beer, porter, mead, cyder, perry, and wines, generally so called. As the principal object of the Treatise is to instruct private individuals and families in these operations, and assist them in judging of the quality of fermented liquors, what may be called the domestic economy of the art will receive particular attention, and full directions will be given for preparing those liquors which habit has rendered so necessary to the comfort of a family; while brewing, as practised in the large way, will be considered in a more general manner.

History.—The history of making fermented liquors is of very great antiquity. We know that Noah understood the preparation of wine from the juice of the grape; and if we are to agree with some mythologists, that Osiris king of Egypt is the same personage with Mizraim the grandson of Noah, and to credit Herodotus, who affirms, that the art of making beer was practised by Isis the wife of Osiris, we may conclude that the origin of brewing *malt liquors* is nearly coeval with the deluge. It is certain, that both wine and beer were known among the Greeks and Romans; and that the Romans were acquainted with ale as well as wine, is evident from the writings of Dioscorides, Galen, and Pliny. Both these nations were distinguished for the variety and quality of their wines,—the *chian* of the former and *falernian* of the latter being particularly celebrated by the ancient poets. It does not, indeed, appear, that much wine was made in Italy till a late period of the Roman empire; and their mode of preparing wine seems to have been rude and simple, though the liquor produced must sometimes have been very strong, as we find it occasionally kept to a much greater age than in modern times.

The vine seems to have been introduced by the Romans both into Gaul and Britain. We find that France was famous for its vineyards in the reign of Vespasian; and it appears from Doomsday-book, that wine was made in England from native grapes at a period anterior to the conquest. How early malt liquors were known in this country is not certain; but, among the ancient Germans, beer was a very common beverage, and seems to have been usually made from malted barley. Cyder, perry, and other factitious wines, are probably of later origin, though the two former are by some supposed to have been introduced into this island by the Romans.

History.

Britain has long been celebrated for its malt-liquors; and in no country have these liquors been carried so nearly to a state of perfection. It appears that some hundred years ago, a sweet ale, brewed probably from malt alone, was in use; but after the introduction of hops from the Netherlands, in the beginning of the sixteenth century, beer brewed from malt and hops became very common. In Queen Anne's reign, it was usual to drink ale and beer mixed together; but soon after, when the brewing of hopped beer was improved, this became a favourite beverage, under the name of *entire butt*, or *porter*. This latter appellation is said to be derived from its being in general use among labouring porters. It is not a little extraordinary, that, soon after hops were generally employed in brewing, an act of parliament was passed prohibiting their use as deleterious to the health; and we are not certain that this act has ever been formally repealed, unless we are to consider the acts lately passed prohibiting the use of other bitters in place of hops as a virtual repeal of it. For a long time the brewing of porter was confined entirely to London; and it was even supposed that it could not be prepared from any water but that of the Thames; but it is now some years since this exclusive privilege has been denied to Thames water, and porter of very good quality is now brewed both in Scotland and Ireland.

Previous to the reign of Charles I. no duty had been levied on malt. This tax was first introduced during the civil war between the king and parliament, and, though at first very moderate, appears to have been extremely unpopular. During the revolutionary war from 1802 till 1815 this tax was extremely productive, having been raised to 4s. 4d. per bushel on English malt, and about 3s. 6d. on Scotch. In consequence of these high duties successful attempts have been made to economise the processes of brewing, especially by introducing the use of raw, or unmalted grain, which, were it not opposed by government, would occasion a considerable saving both of time and money to the brewer. These duties have however contributed to improve our knowledge of the chemical phenomena of brewing, by giving rise to a set of experiments on the comparative properties of different kinds of malt, which took place some years ago at Edinburgh, and were conducted by Drs. Hope, Coventry, and Thomson.

The gross amount of the duties on malt in the year 1813 was, for England L.4,188,450, 6s. 9d. and for Scotland L.134,106, 12s. and it appears that the quantity of malt made in Great Britain during that year exceeded 2,500,000 English quarters; during the following year the quantity of malt made amounted to nearly 3,000,000 quarters. Now, though a considerable portion of this malt is consumed in the distilleries, yet as the distillers now employ at least two-thirds of raw grain, the increased consumption of malt shews that a greater quantity of malt liquor is drunk now than formerly.

It appears, indeed, from Excise reports and tables of the respective London breweries, that the quantity of malt liquors made in this country has of late considerably increased. The quantity of porter made by the principal porter brewers in London had, in nine years, viz. from 1807 to 1815, increased nearly one half. In the year 1812 the quantity of porter brewed by the principal porter brewers in London amounted to 1,491,170 barrels, and the quantity of strong ale brewed by the seven principal houses in London, from July 1814 to July 1815, exceeded 107,000 barrels. The enormous price of foreign wines since the commencement of the revolutionary war, has also rendered the manufacture of made wines an object of considerable importance, and, from the attention lately paid to that subject, and the encouragement it has received from several public bodies, the quality of these wines is now greatly improved. The art of brewing malt liquors has been materially benefited by the improved application of chemistry to the processes, and especially by the introduction of the thermometer and saccharometer, to be afterwards described.

To complete this sketch of the history of brewing, it remains only to notice some of the principal British works on the subject. One of the earliest, and, on the whole, one of the best practical treatises with which we are acquainted is Michael Combrune's *Theory and Practice of Brewing*. The author was a practical brewer, and his directions for the various processes of brewing are in general very judicious; but when he attempts to theorise on these operations he is unintelligible to modern readers, from employing the antiquated chemistry of Boerhaave. It is not a little surprising that, in the new edition of this work, published in 1804, no pains have been taken, even by notes or appendix, to new-model the theoretical part of the work.

In 1784, Mr Richardson of Hull, also a practical brewer, published his *Theoretic Hints on Brewing Malt Liquors*, and *Statical Estimates of the Materials of Brewing, shewing the use of the saccharometer*, works which evince considerable knowledge and ingenuity, but are rendered nearly useless by the mysterious manner in which they are written. In 1802, Alexander Morrice, who styles himself common brewer, published his *Treatise on Brewing*, the introductory part of which contains some useful observations; but when he descends to the particular receipts for making the various ales and beers, he exhibits such a farrago of abominable ingredients, as, if they are really employed by the brewers, must disgust and terrify those who are compelled to purchase and drink the medicated potion. Doctor Shannon, a medical gentleman, who appears to have had numerous opportunities of examining the processes of brewing, and has certainly collected many valuable observations on the manufacture of almost all fermented liquors, published the result of his enquiries in 1805, in a ponderous quarto volume, intitled, "*A Practical Treatise on Brewing, Distilling, and Rectification.*" We cannot but allow to this author the palm of merit for labour and ingenuity; but his work has many and important defects. It consists of several independant books, with a voluminous appendix; and the matter of each, though often very good in itself, is so ill arranged and digested, as to render the perusal of it a heavy and laborious task, while the language in which it is composed is often inaccurate, and not seldom obscure. His proposed improvements in the processes are also difficult, if not impracticable, and the work is rendered much less useful than it might otherwise prove, by the want of an index. The latest work we have seen on the subject of brewing malt liquors, is a thin octavo, of about 140 loosely printed pages, entitled "*The Brewers' Guide,*" published in 1812, by George Lloyd Worthington, and charged at the extraordinary price of five guineas. This work contains a few valuable directions for brewing ales and porter, but they are mixed with a great deal of nonsensical theory and affectation of science.

On the subject of home made wines, under which we include also cyder, perry, and mead, there are but few respectable writers. Besides Dr Shannon's book, which contains a good deal on this subject, some valuable hints by Dr M'Culloch, for the improvement of these wines, may be found in the "*Transactions of the Horticultural Society of Edinburgh.*" They were also published in a separate treatise.

PART I. PRINCIPLES OF BREWING.

The principles of brewing comprehend an account of the various materials employed in the art, and of the process of fermentation, to which these are subjected.

Materials employed.—In considering the materials employed in the preparation of fermented liquors, it will be useful to exhibit a general arrangement of these liquors according to the substances that form their bases, though it will not be necessary to enumerate all their varieties.

I. Malt Liquors.—1. *Ale.* Table Beer, Small Beer.—2. *Porter*, Porter Beer.—3. *Ram-jam.*

II. Fermented Liquors made from Sugars, commonly called Beers.—1. *Treacle Beer*, Spruce Beer.—2. *Ginger Beer.*—3. *Black Beer.*

III. Wines made from, 1*st*, the juice of the grape.—*Red Wines.*—Tokay; Burgundy; Lachryma Christi; Red Port; Claret; Hermitage; Tent.

White Wines.—Champagne; Madeira; Teneriffe; Malmsey; Sherry; White Port; Lisbon; Vidonia; Constantia; Hock; Cape; Rhenish; Mountain; Calcavello; Frontignac; British Grape.

2*d*, Other Fruits.—Currant Red; Do. White; Do. Black; Gooseberry, ripe; Do. unripe; Cherry; Damson; Elder-berry; Orange; Lemon; Raspberry; Strawberry; Quince; Apple, (cyder;) Pear, (perry;) Raisin.

3*d*, Sugar chiefly.—Ginger; Cowslip; Clarey; Elder-flower; Baum; Palm; Birch; Parsnip; Honey, (mead.)

It thus appears that the principal substances which constitute the basis of fermented liquors are malted grain, the saccharine juices of fruits and plants, oney, and sugar, as prepared from the sugar-cane. The other ingredients, as hops, liquorice, spruce, spices, or odoriferous plants, are added to insure the preservation of the liquor, to give it some agreeable flavour, or to counteract some unpleasant property.

Of grain used in brewing.—The processes of the distiller have shewn that a fermented liquor may be prepared from any species of grain or farinaceous seed. Barley, wheat, oats, rye, rice, Indian and Guinea corn, pease, beans, have all at different times, and in different countries, been employed for this purpose; but experience has proved that barley is best adapted to the purpose of brewing ale and beer. Of this grain there are two principal species; the one, more particularly called *barley*, having the grains of the spike disposed in two distinct rows, and the undivided grains larger, specifically heavier, and more mealy; the other, known in this country by the name of *bear*, or *bigg*, of which there are two varieties, one having the spike divided into four rows, the other having it divided apparently into six, with the grains of each proportionally smaller, lighter, and thinner. The average weight of a Winchester bushel of barley is estimated at about 50 lbs. Avoirdupois, while the average weight of the same measure of bigg is scarcely 48 lbs. The cuticle or husk of barley bears a less proportion to the mealy part than that of bigg, but in other respects the composition of these grains is nearly the same. By the chemical analysis of 3840 parts of barley, there have been obtained 44 parts of albumen, 200 of saccharine matter, 176 of mucilage, 135 of gluten, 2580 of starch, 360 of gaseous products, 260 of husk, (consisting chiefly of siliceous earth and gluten,) and about six of phosphate of lime.

Malt.—Although raw grain may be employed for making fermented liquors, it is found most advantageous to convert the grain into malt. By this process, which is merely causing the grain to vegetate, and stopping the vegetation when it has reached a certain degree, the texture of the mealy part is rendered looser, and this part becomes more diffusible in water, while the saccharine principle is more completely evolved. In the process of malting there are reckoned four stages; *steeping*, *couching*, *flooring*, and *kiln-drying*.

1*st*, *Steeping* is performed by putting a certain quantity of water into a square cistern, lined with stone or lead, called the *steep*, which is situated at one extremity of the malt-barn, and usually sunk in the earth, and then throwing in such a quantity of barley as to be completely immersed in the water. The barley is then stirred and levelled, and left to steep for a period not less than forty hours, and which is generally from 50 to about 120 hours, according to the season and the kind of grain. Thus bigg requires a shorter time for steeping than barley, and in cold weather the grain requires a longer steeping than in hot weather, to produce the same effect. While in the steep, the grain undergoes several changes. By imbibing a quantity of water it is increased in bulk and weight, while part of its outer surface is dissolved in the water. Hence it is customary, though not absolutely necessary, to change the water at least once during steeping. Some air, which proves to be carbonic acid or fixed air, is extricated, and the grain when dried is found to have lost part of its weight.

2*d*, After the grain has been sufficiently steeped, it is removed from the cistern and spread upon the floor, so as to form a square heap, a foot or sixteen inches thick. It is now said to be in *couch*, and remains in this situation for about twenty-six hours. During this time the grain becomes hotter, and a moisture appears upon its surface, whence it is said to sweat; but it does not in general begin to sprout except in the middle.

3*d*, When the grain has remained thus long at rest, it is spread out upon the floor in a thinner body; and as the heat now considerably increases, it is repeatedly turned over and spread thinner for about a fortnight. During this time the incipient vegetation that had commenced in the couch proceeds. Little roots grow out at one end of the grain, and the rudiments of a stem called *acrospire*, arise from the same extremity, and push towards the other end between the husk and kernel, till they grow nearly two inches long. In the mean time the kernel becomes dryer, whiter, and acquires a sweet taste. The great object of the maltster is to conduct the process to this stage, and there to check it. This is done by exposing the malt successively to fresh cool air, so as to prevent the temperature from rising too high, while at the same time the moisture is partially dissipated, so as to prevent the overgrowth of the *acrospire*. Of course the hotter the season, and the greater the quantity of malt, the more frequently must it be turned over and the thinner it must be spread. It appears that during this process a slight degree of fermentation takes place, and a quantity of vinous spirit is produced. The time during which malt lies on the floor varies with the kind of grain, and with the different modes according to which the maltster conducts the process. In general, it lies from eight to twelve days. The flooring should cease when the *acrospire* has reached the distant extremity of the grain, as when it grows too long the quantity of saccharine matter in the malt is diminished.

4*th*, In order completely to check the progress of vegetation and arrest the malt in its most perfect state, it is exposed to a considerable heat, so as speedily to dissipate the superabundant moisture. With this view it is removed to the *malt-kiln*, which is a building composed of two floors. In the lowermost floor is kindled a fire of coak or charcoal. Above this, at a sufficient height, is extended a floor of hair-cloth, wire-cloth, or earthen or metallic plates pierced full of small holes; but hair-cloth or wire-cloth is generally preferred. Upon this the malt is spread to a thickness of from three to six inches; and the fire, which is at first very moderate, is gradually increased till the heat rises to such a temperature as experience has shewn to be the most proper for producing the kind of malt required. This temperature varies from 140° to about 186°. During the continuance of the heat, the malt is repeatedly turned, and spread, so as to expose every part as equally as possible; and when it appears to be sufficiently dry, the fire is damped, and the malt suffered gradually to cool. While cooling, however, it is trampled on and turned over to break off the radicles, or *cummings* as they are called, as at this time they are more brittle than afterwards. When the malt is quite cool, it is removed, and subjected to an operation called *cleansing*, to separate the *cummings*. This is usually done by means of *fanners*, producing such a current of air as to blow off the cummings, which are the lighter parts of the malt; and when this is completed, the malt is stored, ready for the market. By the process of malting, the grain is diminished in weight by about one-fifth; but it is generally increased in bulk. It appears, that the better the quality of the grain, the more it is increased in bulk. Thus, 100 bushels of English barley will average 105 bushels of malt; while inferior barley, or *bigg*, is often diminished in bulk, 100 bushels of *grain* not producing more than 99 of malt.

Change induced.—Here it may be proper to explain a little more at large the nature of the change which grain undergoes during the process of malting. It has been already stated, that the kernel of barley contains a large quantity of starch, together with some gluten and mucilage; but, in the raw grain, these constituents are cemented together into a hard coherent mass. Now, after malting, the starch becomes loose and friable, and a considerable part of the glutinous and mucilaginous matters has disappeared, having been consumed, as some suppose, in the formation of the roots. This starch, too, which in the raw state seems not very soluble in water, has its solubility increased by malting. It is estimated that malted barley loses about half its weight by infusion in hot water.

Varieties of malt.—According to the different degrees of heat to which the grain has been exposed in malting, or, rather, according to the manner in which the heat has been applied, malt is distinguished into three varieties, denominated, from the colour of their infusions, *pale*, *amber*, and *brown*.

It was formerly supposed, that these varieties were uniformly produced by increased degrees of temperature, the pale malt being produced by the lowest, and the brown by the highest degrees of temperature. Accordingly, Mr Combrune has given a table, in which he marks the colour which the malt acquires at various degrees of heat, from 119° to 176°; from which it would appear, that malt dried at the first of these heats is white, at 138° amber, at 148° brown, and at 176° black. Now it appears from later experience, that malt may be exposed to a heat very gradually increased to 175° and still retain its pale colour, while, if the heat be suddenly applied, though it should not reach nearly so high a temperature, the surface will become brown, or even charred.

As custom has rendered it necessary for brewers to employ malt of different colours, or substitute some colouring matter to give their liquors their proper shade, the maltster must regulate his heat accordingly. At the same time it must be remarked, that in proportion as the malt is more highly dried, especially if it assume a dark colour, in the same proportion is its real strength diminished. So well are the brewers of the present day convinced of this, that they now generally employ a greater proportion of pale malt, and colour their liquor artificially, so as to suit the taste of the public.

Test of malt.—It is of the utmost consequence to the consumer of malt to be able to distinguish good malt from bad. In acquiring this talent, however, much depends upon experience; and we are not sure that any great reliance is to be placed on the rules laid down by practical brewers for this purpose. One of these tells us, that the best way he knows "is to chew some of it in your mouth, and if you find it sweet and mellow, has a round body, breaks soft, is full of flour all its length, smells well, and has a thin skin, *then* it is good. If it is hard and steely, and retains something of a *barley nature*, it has not been rightly made, and will weigh heavier than that which has been properly malted." It is more difficult to judge of the quality of the high dried than of that of the pale malts; and, indeed, the most certain way of judging is by the *saccharometer*, as will be afterwards explained.

Malt is best preserved by piling it in heaps in a close dry loft; in which situation it will keep well for upwards of a year. Dampness injures it much, both as it renders the grain less mealy, and exposes it to the attacks of weevils.

Hops.—The principal constituents of hops are a bitter principle, capable of being dissolved in water, and a fragrant essential oil, diffusible in water, but not extremely volatile. They are of various qualities, according to the soil in which they are produced, and the manner in which they are preserved. Three kinds are in most repute, Kent, Worcestershire, and North Clay, of which the first are considered most suitable for the making of porter, and the second for the finer ales. The hops should be gathered before they have hung so long as to acquire a brown colour; and after being dried, which is usually done in a kiln, they should be put up in close bags, and well packed. They are afterwards stowed away in a dry close loft, the bags being packed close together to keep out the air and moisture.

New hops, that is, those which have been kept for about four months, are preferable to those which have been kept for a twelvemonth. In judging of them, attention is to be paid to the colour, smell, and feel. They should be of a bright yellowish-brown colour, and a fragrant smell, and, without being damp, should have a soft and oily feel.

The use of hops in brewing is partly to give an agreeable bitter to malt liquors, and partly to check their too great propensity to fermentation, and thus preserve the liquor from becoming sour. For these purposes, they are boiled with the infusion of malt for a longer or shorter time, according to circumstances which will be hereafter noticed. It has been proposed, instead of boiling the hops in substance, to make a strong extract, by gently boiling, or rather macerating the hops in a quantity of water sufficient to cover them, and mixing this extract with the wort at a proper temperature. From the long maceration which would be necessary to form such an extract, we are not sure that it would be any considerable improvement in the process of brewing.

Substitutes for hops.—From the high price to which hops occasionally rise, it has been proposed to substitute in their place various other bitters and narcotics. As the hop is not what is termed a *simple* bitter, but possesses properties similar to opium, it is not easy to find a substitute that by itself shall answer all the purposes of hops. Opium itself, therefore, and the berry called *cocculus indicus*, have sometimes been combined with the simple bitters of *quassia* or *gentian*. Probably neither of these bitters is more unwholesome than the hop, though their taste is certainly much less agreeable. We do not apprehend any great danger from the use of opium; but the *cocculus indicus* is a poisonous berry, whose use ought to be proscribed by the utmost rigour of the law; and we cannot with-hold our astonishment at seeing this drug recommended as an ingredient in malt liquors by one of the latest writers on practical brewing, who has been already mentioned in the historical introduction.

Wort.—An infusion of malt constitutes the liquor called *wort*, or *sweet-wort*, the properties of which must now be examined. Wort is a transparent fluid, whose colour is more or less intense according to the colour of the malt from which it is made. It has a luscious sweet taste, and contains a considerable quantity of sugar, in proportion, of course, to the quantity of malt, and the time of infusing. The wort first drawn off, therefore, is the strongest, and each succeeding infusion proportionally weaker.—Besides sugar, there is found in wort a quantity of mucilage, some starch, and some gluten, or albumen, which last separates when the wort is boiled. From its holding these matters in solution, wort is, of course, of considerable density. The mode of estimating this will be explained hereafter.

Fermentable juices.—In considering the nature and composition of those fermentable juices of fruits from which wines are made, it will be proper to class them according to their qualities. In the enumeration at page 5. the *juice of the grape* occupies the foremost rank, as being that from which alone good wine is made without any admixture. The component parts of the juice are pretty much the same, in point of number, in all the numerous varieties of grapes, though they differ in proportion, according to the climate and cultivation. It contains a considerable quantity of *sugar*, especially in those grapes that are the produce of a warm climate. To the sugar it owes its richness; and those grapes which are most highly ripened produce in general the fullest-bodied wines, as the *Muscadine*, *Tokay*, *Frontignac*, and *Black Cluster*. It also contains two or three vegetable acids, as the *tartaric* in combination with potash, the *gallic*, and probably the *citric*. From these it derives its sharpness and astringency, though this latter depends more on the husk of the grape, and is particularly sensible in the red grapes, especially the *claret*. A peculiar *colouring matter*, apparently of a resinous nature, is combined with these principles, and is also most conspicuous in the red grapes, in which, except in the claret, it resides chiefly in the husk. A little *mucilage*, and a peculiar *aromatic* principle, probably an essential oil, are the only other ingredients that require to be noticed here. To this last the grapes owe their peculiar flavour, which is most remarkable in the white and red *Frontignac*, the white *Muscat* of Alexandria, and the Tokay. Much of this, however, is lost in fermentation; and wines generally receive their flavour, as well as colour, from some artificial addition.

In the *raisin*, or dried grape, few of the constituents of the recent juice remain, except sugar and mucilage, with a little astringency, chiefly in the stalks. We have, therefore, placed it as a connecting link between the fruits and sugar.

The juice of *currants* nearly resembles that of grapes, except that it contains little or no tartaric acid, and its saccharine principle is in a less concentrated state; hence probably, like the juice of most of our northern fruits, it is more disposed to run into the acetous fermentation. *Gooseberries* contain *citric* and *malic* acids, the former of which is the chief constituent in *oranges* and *lemons*, and the latter in *apples*, *pears*, and *quinces*. The *malic* acid is more abundant in unripe than in ripe gooseberries; hence the wine made from this fruit is different, according to its state of maturity. The juice of the *elder-berry* is somewhat like that of the currant, but contains more colouring matter and less acid. It is sometimes employed to heighten the colour of other wines. *Cherries* and *damsons* contain less juice than those fruits we have already mentioned; that of cherries is the sweetest, that of damsons the most austere. The raspberry and strawberry are remarkable for little, but the juice of the former has a peculiar rich flavour, much of which it retains in the wine. All these fruits, however, except apples and pears, require the addition of sugar in brewing wine from them.

Sugar.—Sugar alone is capable of making a vinous liquor, and is undoubtedly the principal fermentable ingredient in the must from which all these liquors are produced, though it be variously modified by the admixture of other bodies. Sugar is employed as the basis of vinous liquors under several forms: 1*st*, *Pure*, as derived from the juice of the sugar-cane, in which state it is used in making all the wines in the third division of the arrangement, except *mead*: 2*d*, In the state of *molasses*, or *treacle*, under which form it is used for making a kind of table-beer, generally called *treacle-beer*, and in the preparation of *spruce-beer*, and we believe it not unfrequently forms the basis of those domestic wines which are to have a deep colour: 3*d*, In the state of honey, which, as has been already noticed under Bee, Vol. I. p. 604, is merely a saccharine juice that has undergone an animal change; this is used chiefly in the making of mead, but is also prepared to be employed in the brewing of made wines: And, 4*thly*, as it exists in the juice of some plants, as the *palm*, the *birch*, and the *parsnip*, from each of which a good wine may be produced. There is another saccharine juice that is sometimes employed in brewing porter and high-coloured ales, which, though of a coarser quality, partakes much of the nature of the 4th order of sugars, namely the juice of *liquorice-root*, either as expressed from the fresh root, or in its inspissated state, called *Spanish liquorice*, or *black-sugar*. Both of these are heavy sugars, but where colour is wanted it may be a very innocent addition.

The odoriferous and aromatic substances of baum, clarey, elder-flowers, cowslip, and ginger, are merely added to a saccharine vinous liquor to give it a peculiar flavour or pungency.

Spruce.—The young tops of the *spruce-fir* were long ago employed, either infused or boiled in wort, for impregnating ale with diuretic and antiscorbutic qualities, and the liquor thus formed was much used

Principles.

at sea, under the name of *spruce-beer*. Of late an extract, or *essence*, of spruce has been prepared, and sold in stone bottles; and this essence is added to wort, or must, as will be hereafter directed.

Water.—Among the substances employed in brewing, one so necessary as *water* must not be passed unnoticed, though brewers do not at present attach such importance to its qualities as formerly. In the old works on brewing, a great deal is said on the chemical properties of this fluid, and it was generally supposed that the purest water was the best adapted to the purposes of brewing, as being lightest and most wholesome. River water was preferred to well water, and Mr Combrune has given a long table of the comparative properties of Thames, New-river, and Hampstead water, those formerly used in London. Of late, however, it has been found that the substratum of the soil on which London is built abounds with springs of excellent water, and every brewery is now provided from this ample source with wells whose water answers all the purposes of the establishment. Some modern brewers still maintain that soft water is best suited to the making of porter, and hard-water for ales. In general, any spring-water that is not too hard, and has no unpleasant mineral impregnation will make very good liquor; but rain-water, as being often muddy and abounding in corrupt vegetable matter, should be avoided, as, independent of the impurities it contains, it is said to accelerate fermentation and dispose to acidity. The quality of water may be sufficiently ascertained for the purposes of brewing, by the usual criterions of its transparency, insipidity, want of smell, and its forming a smooth lather with soap. If it be desired to have a surer analysis, it may be obtained by having recourse to the tests to be afterwards noticed in another place.

Fermentation.—To explain the phenomena and nature of fermentation, by which such important changes are produced on *must*, we shall take one of the simplest examples, by supposing a vinous liquor to be formed from sugar and water set to ferment. Let three pounds of powdered lump sugar be dissolved in a gallon of spring water, simmering it over the fire, and removing the scum as it rises. Set the clear liquor by to cool till it acquires the temperature of 60° of Fahrenheit's thermometer, and then put into it a piece of toasted bread, having both sides covered with yeast. The solution of sugar is *must*, as all liquors capable of being, by fermentation, converted into wine, are called; it is transparent, has a mild sweet taste, is specifically heavier than water, has in it little or no air, and does not sparkle when poured into a vessel. When this liquor has stood for some time after the yeast has been added to it, keeping up the temperature as near to 60° as possible, the following appearances take place: The transparent liquor gradually becomes turbid, and particles of air are seen forming in it and rising to the surface, where by degrees they form a coherent scum, which, if the quantity of must be considerable, assumes an irregular surface and considerable thickness, an intestine motion is evidently going on in the liquor, and the temperature increases. After these appearances have continued for a time, longer or shorter according to circumstances, the intestine motion diminishes, the scum becomes flatter, and, if not removed, sinks gradually to the bottom. If this be removed, and the liquor be drawn off cautiously from the sediment, it is evidently much altered in its properties. It is again become pretty clear, has lost much of its sweet taste, and has acquired one that is sharp and agreeably pungent, producing an exhilarating effect on the spirits; its specific gravity is diminished, so as often to be less than that of water, and it abounds with air.

Principles.

Such are the ordinary phenomena of vinous fermentation; but they are variously modified by circumstances, which now demand particular attention. These are chiefly the nature, quality, and quantity of the must, its degree of concentration, the quality and quantity of the yeast or ferment, and the temperature of the atmosphere.

1*st*, Different kinds of must pass more or less readily into a state of fermentation. The juice of the grape, at least in warm countries, and that of apples and pears, are easily fermented in a proper heat, without any addition of yeast; the juice of other fruits, and must prepared from sugar or treacle, also readily ferment, but, without great care, run speedily into the acetous stage, and form vinegar. These, therefore, require a ferment. Wort made from malted grain will not ferment well without yeast, and an infusion of raw grain scarcely at all without this addition, which it requires in considerable quantity. The quantity of the must is also a consideration of some importance, and experience has shewn that fermentation succeeds best when the liquor is in moderate quantity. Hence the vessels in which brewers set their worts finally to work are proportionally small, but numerous. This, however, is rather from convenience than necessity, as the large vessels in which the fermentation is begun are much less manageable.

2*d*, The *degree of concentration*, or density of the must, has an influence in accelerating or retarding fermentation. In the instance given above, the quantity of saccharine matter is sufficient to produce a vinous liquor of moderate strength, and to ferment readily. Were it to contain much less sugar, it would soon turn sour; and were it to hold much more in solution, the liquor produced would be stronger, but the must would not be so easily fermented. A saccharine fluid of the consistence of syrup can scarcely be made to ferment.

3*d*, *Quality, &c. of the ferment.*—*Yeast*, or *barm*, the substance usually employed for promoting fermentation, is the glutinous opaque *head* that rises on fermenting liquors. When good it is of considerable consistence, and may even be reduced to a dry state without losing its fermenting powers. It is a very heterogenous substance, as will appear from the following analysis of Westrumb. From 15360 parts of fresh yeast produced from beer, this chemist obtained 13 of potash, 69 of lime, 15 of carbonic acid, 10 of acetic acid, 45 of malic acid, 120 of vegetable extractive, 240 of mucilage, 480 of gluten, 315 of saccharine matter, 240 of alcohol, and 13595 of water. Which of these, or what combination of them, constitutes the fermenting principle, has never been completely ascertained. We know, however, that, in

Principles.

drying, the *alcohol*, *carbonic acid*, *acetic acid*, and *water*, are exhaled; and as wort contains much saccharine matter, and still requires yeast to work it, it can scarcely be supposed that any of these five principles contribute to the process, unless, perhaps, the combination of sugar with gluten, or extractive, may form a ferment. When yeast is suffered to stand for some time, there collects on its surface a quantity of matter between curd and gluten; and it has been supposed that this is the fermenting principle. But all this is at present hypothetical.

Yeast is of very different qualities, according to the way in which it is obtained. What flows over the edge of the fermenting vessels is considered the purest; and what collects at the bottom, as being mixed with the impure lees, is considered the worst. Porter-yeast, too, is not thought so good as that from ale and table-beer. Yeast, when kept in a fluid state, gradually loses its good qualities by becoming stale, and then must be used in greater quantity. For the purpose of brewing, fresh yeast is to be preferred. The activity of the fermentation depends also on the quantity of yeast employed, and is in general greater in proportion to this quantity.

4th, Temperature.—Nothing is of more importance to the success of fermentation than a well-regulated temperature, both in the liquor to be fermented and in the atmosphere of the place where the fermentation is carried on. Much below 50° no fermentation takes place; and if it be raised much above 70°, the vinous fermentation proceeds too rapidly, and speedily terminates in the acetous. In cold weather, it is found necessary to set the mash to work at a high temperature, sometimes as high as 70°; while in warm summer weather, during which brewing is seldom practised from choice, it is necessary to lower the temperature of the liquor as much as possible, to 50°, or even lower. This regulation of temperature is the more necessary, as the increase of temperature that takes place during the process is often very considerable; the liquor sometimes rising above 20° above the heat of the must, for which, of course, allowance must be made.

Effects of fermentation.—Without entering into a chemical explanation of the process of fermentation, which would here be out of place, we shall consider the nature of the changes that result from it. The sharp agreeable taste of fermented liquors is owing partly to the carbonic acid which most of them contain, and partly to the alcohol or ardent spirit which has been formed. All of them contain alcohol, though the proportion of this principle varies exceedingly, from small beer, in which it is scarcely to be detected, to the strongest Malmsey wine, which seems to contain it in the greatest quantity. Malt liquors, treacle, ginger, and more especially spruce-beer, cyder, perry, and Champagne-wine, abound in carbonic acid; while in the other liquors that have been enumerated, this acid is scarcely sensible, except when they have been improperly managed. The diminished specific gravity, or *attenuation*, as it is termed in the language of the brewery, is owing entirely to the alcohol produced, and is of course greatest in the *wines*, malt-liquors being proportionally less attenuated in consequence of their containing more undecomposed sugar in solution. This is particularly the case with the strong ales brewed in Edinburgh; in making which, fermentation is not carried nearly so far as in the home-brewed October of the south. Many wines, especially white wines, Malmsey, Mountain, Malaga, and most British wines, also contain much undecomposed sugar, and are hence called *sweet* wines; while those which contain little sugar are denominated *dry* wines.

Principles.

The *attenuation* produced in liquors by fermentation deserves particular attention, as it is in general a measure of their vinous strength. It is estimated by the specific gravity of the liquor taken before and after fermentation; and this specific gravity may be taken either by the common hydrometer, or by the saccharometer, to be afterwards described. The attenuation varies in the different liquors, being least in malt liquors, and greatest in the wines. Taking the specific gravity of water at 60° at 1.000, that of ale-wort varies from 1.0640 to 1.11275, and that of fermented strong ale from 1.0205 to 1.0500, or even higher. The average specific gravity of wort for making brown-stout porter is 1.0624; while that of brown-stout, after being some time bottled, is 1.0106. The average specific gravity of common porter-wort is 1.0500; and that of the brewed liquor is from 1.0130 to 1.0170.

PART II. PRACTICE OF BREWING.

Chap. I. Of the Apparatus employed in Brewing.

Utensils.—Before describing the processes of brewing, it will be necessary to say something of the utensils or instruments employed. These differ according to the nature of the operations, and the scale on which they are conducted.

Mills.—A mill is required for grinding or bruising many of the substances employed in brewing, as *malt*, *apples*, *pears*, *quinces*. For domestic purposes, malt is ground in a large hand-mill, so coarsely set as merely to break the grains into pieces, without reducing them to meal. In large breweries the malt mill is usually fitted with two iron rollers, between which the grains pass, and are thus sufficiently bruised. The cyder-mill consists of a circular block of hard stone, 9 or 12 inches thick, and from $2\frac{1}{2}$ to $4\frac{1}{2}$ feet in diameter, so fixed as to roll on its edge within a circular stone trough, the bottom of which is rather wider than the edge of the urn. In selecting stone for this purpose, care is taken not to employ limestone, as the acid of the fruit would dissolve a part of the stone. Sometimes the mill is formed of a strong square box, inclosing the usual grinding apparatus, supported on two stools, furnished with a hopper above for securing the fruit, and a spout below for letting out the juice that is squeezed from the apples, and generally worked by hand. In the large way, the former mill is placed in an apartment below

Apparatus. the apple loft; and in the floor of this loft is a trap-door with a tunnel leading from it towards the floor of the mill. A horse pushes round an axle on which the runner is fixed, and the pulp is occasionally stirred till it be sufficiently ground. The same mill answers for apples, pears, or quinces, and those pulpy fruits or roots of which domestic wines are made.

Press.—In making cyder, perry, grape, raisin, and parsnip wine, it is necessary to express the juice of the bruised materials with considerable force. For this purpose there is used a very simple press, consisting chiefly of a strong wooden frame-work, in which is fixed a stone floor at a convenient height, and having a stout moveable wooden plank connected with a very strong wooden screw, by the action of which the plank is made to press strongly on whatever is placed on the floor. It was formerly the practice to cover the floor of the press with lead, but as the acid of the fruit acts upon the lead, and produces a very deleterious substance, this is now generally disused. The press should be situated as near as possible to the mill, to prevent waste of liquor and loss of time. In pressing the fruit, &c. the pulp is placed on hair-cloth, and when ten or twelve layers are formed, the whole is submitted to pressure, by turning the screw by means of a long lever.

Boilers.—For heating water and boiling the liquor previous to fermentation, there are employed boilers, which are called *coppers*, from the metal of which they are generally made. In the small way, the copper need not be larger than to contain a hogshead or two, and may be of the ordinary cylindrical figure, having the mouth closed by a wooden lid in two parts. It is surrounded by brickwork, which serves both to support and defend the copper, and to heat it by a furnace below, while the smoke is carried off by a chimney behind. In public breweries, where the boiler sometimes contains 300 barrels at once, and where there are two, three, or even four of these enormous vessels in one establishment, the copper is a very complex structure, contrived for the purposes of economy and dispatch. The improved brewing-copper may be said to be composed of three principal parts; 1*st*, The body, which is a cylindrical or rather conical vessel, formed of immense plates of copper or cast-iron, fastened together by rivets of copper or wrought-iron, having a broad rim at the top, by which it is suspended on the surrounding brickwork, while its bottom, which is two or three inches thick in the centre, rests on strong jambs of brickwork, leaving a space round the copper for the flame and heat to circulate; 2*d*, A hemispherical dome, fitted close to the upper rim, so as to retain the steam, except what prudence requires should escape through a safety valve, and having a large cylindrical opening through which passes the shaft of an apparatus for stirring up the contents of the boiler, while it is so secured that the steam cannot be lost by this outlet; 3*d*, A cylindrical metallic vessel of considerable dimensions, made so as to cover the dome, except its central tube, and to be heated by the steam that rises into the concavity of the dome, and thus has its contents brought nearly to the required heat without waste of fuel. This last is called the upper copper, and is used for receiving the liquor that is afterwards to be boiled in the lower copper, to which it is admitted by holes furnished with valves, and opening through the dome. In large breweries the coppers are filled by pumps from a reservoir called the liquorback, and the boiled water or liquor is conveyed from the copper by means of tubes furnished with stop-cocks. Apparatus.

Mash-tub, or *Mashing-tun.*—To extract the fermentable juices from malt by hot water, brewers use a large tub called the *mash-tub* or *mashing-tun.* In domestic brewing this vessel is made to hold a hogshead or two, and is generally somewhat of a conical form, broadest at the bottom, where there is a hole for letting out the liquor. In the old way, this hole is made immediately through the bottom, near that side which is to be in front, and is closed with a wooden pin that reaches above the edge of the tub. This plug is covered with a long conical wicker basket, broadest next the bottom of the tub, and so contracted at the top as just to admit the top of the plug, and a wooden wedge for adjusting the plug, so as to enlarge or contract the hole in the tub. A better method, which is universally adopted in large breweries, is to have the mash-tub made with a false bottom, a few inches above the real bottom, pierced full of holes so small as not to allow the malt to run through, but to admit water to rise or fall through it. In large works the mash-tun is also a complex machine, and the body of it is sometimes formed of cast iron, with a false bottom of wood, and is supported upon iron posts, connected by the frame-work with a central column that is hollow, and forms part of a tube which brings the hot water from the copper into the space between the two bottoms, so that it may rise up through the holes into the body of the tun and wet the malt there contained. It is necessary during *mashing* frequently to stir up the malt to make the water act more fully on it; an operation which is easily performed in domestic brewing with a stick or small rake, and, in the large way, was formerly done by several men stirring up the *goods* (as the mashing malt is called), with long rakes, and afterwards agitating them with wooden paddles or oars. At present *mashing machines* are generally employed. These consist of a perpendicular axis or shaft, passing down the centre of the mash-tun, and having projecting from its sides arms to which are attached wheels, chains, and other apparatus, that, when the axis revolves by the action of machinery, stir up and agitate the goods.

It is now generally admitted that that the processes of brewing should be conducted in close vessels; and in the old way the mash-tub was covered with a wooden lid separated into two. The cover is now made as close as possible; and it has even been proposed to cut off all communication with the air, by inclosing the mash-tun within another vessel, with a space between, into which steam is admitted, so as to keep the contents of the tun at the same temperature. In public breweries the mash-tun is usually placed below the floor of the malt-loft, so that the malt is expeditiously introduced through a trap-door.

Apparatus.

The ordinary mash-tub may be employed in the making of those wines which require the ingredients to steep for any considerable time, as *raisin* wine.

Underback.—A tub or vessel, nearly of the same dimensions with the mash-tun, is placed below this to receive the liquor (*wort* or *must*), after the making is completed. This vessel is called the *underback*, and is formed of the same materials as the mash-tun. In the small way, it is merely a moveable tub, generally of an oval form, and furnished with two handles; in large works it is a fixed receiver, supported on brick-work, and having a pipe communicating with a pump, by which the wort, as it flows from the mash-tun, is drawn up into the upper copper. In private brewing the under-back is generally uncovered, but in public works it is deemed an object to have it close.

Jackback.—In large breweries there is an intermediate vessel called jackback, near the copper, for receiving the wort that has been boiled, and freeing it from the hops by means of a perforated plate within the vessel, before transferring it into the next vessels, into which it is conveyed by pumps. This is unnecessary in small concerns, and the wort when taken from the copper is only strained through a basket from the hops.

Coolers.—In order to reduce the worts to a heat proper for disposing them to ferment to the greatest advantage, they are placed in wide shallow vessels called *coolers*. In domestic brewing there is seldom more than one cooler, which is an oblong wooden receiver, sufficiently wide to contain about a hogshead, but only a few inches deep. It is usually hung at one side to the wall of the brewhouse by strong hinges, and to the other side are attached two strong moveable posts, for supporting it in a horizontal position when filled. At one end, and sometimes at each, near the front, is a hole, stopped by a wooden plug, for letting off the liquor when sufficiently cooled. In public breweries the coolers are very numerous, and proportionally larger and shallower than what we have described. They are situated on tiers above each other, and the walls of that part of the building are constructed with numerous open spaces to admit freely the external air, for the most expeditious cooling of the worts,—a circumstance of the utmost importance in extensive works, as, if the liquors were kept too long at a high temperature, they would become putrid, or *foxed*, as it is termed. When properly cooled they are drawn off from the coolers by pipes, and conveyed into vessels for undergoing fermentation.

Fermenting vessels.—In domestic brewing, the cooled liquors, or the must in making wines, is put into tubs of a size proportioned to the quantity, and these are loosely covered with lids or cloths. In the large way, there is a series of vessels of various sizes, and the liquor is transferred from one to another till it is finally left to work in the smallest. The largest vessel, or *gyle tun*, is usually of a square or oblong form. Into this the liquor is brought from the coolers, and from this it is conveyed into a lesser vessel or *back*; hence into a vessel called the *cleansing vat*; from this into the *working tuns*; and, lastly, into casks that are placed in double rows, in groups of four each, having tubes that unite, and pour the yeast, that would otherwise flow over, into pipes that convey it to a reservoir.

Apparatus.

Store-casks, or vats.—After the liquor is properly fermented, it is *tunned*, or transferred into vessels for keeping. In the small way, it is put immediately into the hogsheads, in which it is to remain till tapped or bottled; but in the large way it is first drawn into immense reservoirs, called *stores*, or store-vats. These are usually sunk in the ground, or inclosed within walls of brick-work, and are capable of holding many hundred barrels. One of them that burst lately in an extensive London brewery, produced effects like an inundation from a river, the liquor flowing from the breach, bursting through walls, and bearing down all before it. From these stores the liquor is raised by a pump, and the casks filled by pipes.

These form the principal apparatus of brewing; but there are several other implements both in domestic and public brewing which may be briefly noticed; as, a large funnel, made of wood, with a metallic tube for tunning the liquor into casks; a gauging rod, for ascertaining the quantity of liquor in the vessels; a *thermometer*, for taking the degrees of heat both of the liquors and the atmosphere; and a *saccharometer*, for ascertaining the strength, or rather density, of the *wort* or *must*. But these last three instruments require a little more examination.

Gauging-rod.—The brewer as well as the exciseman should be provided with *gauging-rods*; and in general there are more than one, for taking the quantity of liquor in barrels in the different vessels. The rod should be divided into inches and tenths of an inch, and when the capacity of any of the vessels is previously known in gallons or barrels, the quantity of liquor which they contain, at any given time, is easily ascertained according to the rules of mensuration.

Thermometer.—The thermometer used by brewers differs but little from ordinary thermometers, except in size and frame. It is larger, and the frame is of metal, with an open handle at top, to which may be attached a cord for letting down the instrument into the copper, &c. It may be filled either with spirit of wine or mercury; the former is more easily seen, but the latter is more accurate, as its changes of bulk are more equable. The scale, which in this country is always Fahrenheit's, need not range lower than 32°, the freezing point, or higher than 212°, the boiling point of water. But besides the common large thermometer, it is usual to have one of a smaller size, for accompanying the next instrument, and taking the temperature of liquors of which it is wished to ascertain the density. The use of this instrument is evident. It is now well ascertained that the various processes of brewing succeed best at certain temperatures. Provided with a thermometer, the brewer can of course act with more precision and a greater certainty of success.

Saccharometer.—This is one of the most important instruments employed in the improved state of brewing. It is a modification of the *hydrometer*, or *gravimeter*, that has long been in use for taking the specific gravity of ardent spirits, and acts on the same principle, that the less the specific gravity of any fluid, the deeper will a body sink in it, and the contrary; but the scale is different, and the degrees are adapted to shew the number of pounds of saccharine extract in each barrel (of 36 gallons) of liquor. There are various instruments of this name whose scales are different. Mr Richardson's was the first employed in this country, and modifications of that instrument by Dring and Fage, and by Atkins, have been much in use. Another by Dicas is said to be preferable, as being founded on more correct principles than Richardson's; and one contrived by Dr Thomas Thomson, and employed by the Excise officers in Scotland, is considered the most accurate. The instrument itself shews the specific gravity of the liquor in which it is immersed, and the weight of saccharine extract it contains is determined by means of a sliding rule that forms part of the apparatus.

The ordinary saccharometer consists of a copper ball, having a graduated scale rising from its upper part, while at the lower is appended a weight by a short cylindrical tube. For more conveniently making experiments, cylindrical tin vessels, called *assay-jars* are used, and of those, the most convenient is a double vessel communicating at one side, so that when the liquor is poured in the whole shall be of uniform temperature. When used, the jar is immersed in a case called a *refrigeratory*, for reducing the heat to 60° by cold water, and when, by the thermometer immersed in one jar, the temperature of the liquor is found to have fallen thus low, the degree to which the saccharometer sinks is noted, and the lower the saccharometer sinks the less saccharine matter the liquor contains.

Dr Shannon has given the form of a journal for noting the important circumstances that occur in the process of brewing, which may be advantageously adopted. The page is supposed to be ruled in ten or twelve columns for noting the following particulars; 1st, the *date* of the brewing; 2d, the quantity of *malt* used; 3d, the quantity of *hops*; 4th, the quantity of *wort in the underback*; 5th, the *gravity* of each wort that is drawn off; 6th, the quantity of fermentable matter contained in each wort; 7th, the quantity of cold wort in the coolers; 8th, the gravity of each wort in a fermentable state; 9th, the net aggregate of fermentable matter remaining in each wort at the above period; 10th, the amount of the fermentable matter extracted from each quarter of malt; 11th, the specific gravity of the liquor after the fermentation ceases; 12th, the amount of attenuation. Tables of a similar nature are employed by Drs Hope, Coventry, and Thomson, in the report made by them to the Board of Excise.

Having now described the principal utensils employed in brewing, it remains, before proceeding to explain the processes, to shew how those are arranged in the private brewhouse and an extensive brewery.

In most private brewhouses there is but one copper, capable of holding the quantity of liquor made at one brewing, which is generally a hogshead or two. As near as possible to the copper, stands the mash-tub, upon a gauntree sufficiently high to admit of the underback standing below it. At some distance from this part of the apparatus, generally along the opposite wall of the brewhouse, is hung the cooler, and sufficient room is left for arranging two or more fermenting tubs below it. If the vessels are large, there are generally moveable wooden spouts or gutters for conveying the liquor the more readily from one vessel to another; and a spout, communicating with a cistern without, is often introduced into the brewhouse.

Few manufacturing establishments are more interesting than an extensive public brewery. The great range of buildings, the enormous size of many of the utensils, and the ingenious contrivances for diminishing labour and expediting the various processes, cannot fail to astonish and delight the beholder. Some of these buildings are erected with arches below, where coals, casks, hoops, &c. are stowed away, and in some convenient part is sunk the well which supplies the establishment with water. Generally near the well is the engine-house, containing a steam engine that forms the great centre of motion for all the machinery employed. By this engine are worked the pumps, which raise the water to the summit of the building, where there is generally a large reservoir for containing it, and which extract the wort from the underbacks, or convey it to the coolers. By means of the same engine, the mills which grind the malt are set in motion, the machines contained in the mashing-tuns, and the apparatus for stirring up the contents of the coppers perform their several offices, and sacks of malt and hops are drawn up from carts and conveyed to the lofts where they are to be stored.

The principal floor of the brewery is occupied by the coppers, near which stand the large fermenting vats, or gyle-tuns, and jackbacks, and, at no great distance, the mashing-tuns, with each its under-back below. In one wing stand the immense store-vats, with smaller ones occupying the intermediate spaces; and in the other are ranged in double rows the cleansing-vats that are supplied from the large gyle-tuns. An upper floor is occupied with the malt-mill, and near it are large binns for containing the ground malt. Above these are lofts for containing the stores of malt and hops, the malt-loft being generally over the mill; and in the upper part of one wing are placed the coolers, one above another.

A very complicated apparatus is by no means necessary for brewing very tolerable liquor. We have known some notable housewives make excellent table beer, and very agreeable ale, with the following simple utensils. A large broth pot served for a boiler, and a firkin, or small cask cut in two, supplied the rest of the apparatus. The larger half of it formed the mash tub, while the smaller end answered the triple purposes of underback, cooler, and fermenting vat; a cask of sufficient dimensions to hold the produce of one brewing, and a few dozen of bottles to contain the liquor after it was sufficiently purified in the cask, completed the apparatus for domestic brewing; and the process was repeated whenever the cask had been emptied into the bottles. A similar apparatus answers very well for making small quantities of domestic wines and vinegar.

It will easily be supposed that all the utensils of the brewery, and the vats and casks in which the liquors are to be kept, must be perfectly sweet and clean; and indeed this is one particular in which some brewers and dealers excel their brethren, and never fail to find their account in it. Particular directions on this subject would be out of place here, but shall be given when the processes of brewing have been described.

Chap. II. Of the Processes of Brewing.

The processes of brewing are more or less numerous, and more or less complicated, according to the nature of the liquors intended to be produced. The brewing of malt liquors in general requires a greater complication of processes than the making of any other fermented liquors, and this shall form the subject of the first section.

Sect. I. *Brewing of Malt Liquors.*

Besides the preparatory operation of *grinding*, there are six steps of the process of brewing malt liquors to be considered, viz. *mashing*, *boiling*, *cooling*, *fermenting*, *cleansing*, and *tunning*.

I. *Grinding.*—In grinding malt the chief object is to break every grain sufficiently, without reducing it to the state of meal, as in that state it is very liable to what the brewers call *setting*, that is, clogging into compact masses when the hot water is mixed with it, a circumstance which prevents the water coming sufficiently in contact with every part of the malt, to extract from it all its saccharine principle. This setting also diminishes the *quantity* as well as the *strength* of the wort, by preventing so much of the impregnated liquor from escaping. The malt may be ground properly in a common corn mill, providing the stones are set at such a distance as to crush the grains without reducing them to powder; or this operation may be more certainly performed by means of the iron rollers mentioned above. For domestic purposes, nothing succeeds better than a large steel coffee-mill, set loosely; and even in extensive works, an apparatus on this plan may be adopted, of sufficient power for grinding six or eight quarters of malt per hour. It is usual, especially in home brewing, to have the malt ground some time before using it, but then it should be kept in a cool dry place. For domestic brewing the malt is often purchased from the dealer ready ground, and where the dealer can be depended on this is very convenient; but as it is more difficult to judge of the quality of the malt when ground than when entire, it is safer to purchase it in this latter state.

II. *Mashing.*—The process of mashing consists in infusing the malt in such a quantity of water, at a proper temperature, as may be sufficient to extract its saccharine and farinaceous principles, in the degree of concentration suited to the purposes for which the liquor is intended. The mode of conducting the process differs according to the apparatus. In domestic brewing the water is usually first put into the mash tub, and the malt is added when the water is of a proper temperature. Where there is not a false bottom, the conical basket and wooden plug, already described, are first fixed so that the hole in the bottom of the tub shall be completely stopped; and when the *grist*, or *goods*, as the malt is called, is introduced, the whole is well stirred for a considerable time. The tub is then well covered, and the goods are suffered to steep for two or three hours, according to the quantity. This is what brewers call the *standing of the mash.* In the large way, the *goods* are first put into the mash-tun, and the water, at the required temperature, is introduced from below the false bottom, through the holes of which it rises and penetrates through the goods in every direction. While this is going on, a continual agitation is kept up within the mash-tun, by the motion of the mashing apparatus, and the whole is left to stand for an hour or thereabouts, according to circumstances to be immediately noticed. In both ways, when the mashing is completed, the wort is drawn off into the underback, or, in the language of the brewery, the *tap is set*; and a fresh quantity of hot water is introduced among the goods, for a second mashing, which is conducted nearly as before.

The definition of mashing just given, suggests a variety of circumstances to which the brewer must attend in conducting the operation. These are chiefly, the *proportional quantities* of *malt* and *water*; the *temperature* of the latter; the *number of mashes* intended to be taken; the length of time which each mash requires.

1. *Proportions of malt and water.*—Supposing the copper full of water to be employed, which is generally the case, the proportional quantity of malt depends on the proposed strength of the liquor, and the time during which it is to be kept. In domestic brewing, where good ale is to be made, from six to eight bushels of malt to the hogshead is a very good proportion; and if the ale is to be very strong, and to be kept above a year, forming what is called *old beer*, ten or twelve bushels are often used to the hogshead. Where table beer is made from fresh malt, which is seldom done, two bushels to the hogshead is a good proportion, and less for small beer. In extensive breweries, where the copper holds from 50 to 300 barrels, from 25 to 150 quarters of malt are mashed at once. The whole quantity, either of malt or water, is seldom put into the mash-tun at once. It is thought best first to admit such a quantity of water, say one barrel to each quarter, as shall form, with the goods, a stiff mixture, which is well stirred before the rest of the water is added. This is called *stiff mashing*, and is thought to prevent the settling of the goods, while it ensures the full extraction of the principle of the malt. A small portion of the malt is kept out at first, and when all the water to be employed in one mashing has been introduced, this malt is sprinkled over the surface, and, gradually falling down through the water, imparts to it most of its goodness. The quantity of water that may be impregnated by any given quantity of malt, or, as the brewers speak, the *length that may be drawn*, depends much on the head and quality of the malt. In general, *pale* malt will bear a *greater length* than brown, and the better the malt the greater length may be drawn from it, provided the *goods* have not been allowed to *set*.

2. *Temperature of the liquor.*—Much of the success of brewing depends on the temperature of the water

employed in mashing. If this be too cold it does not extract all the virtues of the malt, and if its heat be too high it occasions the goods to set. The common mode of regulating the temperature, before the introduction of the thermometer, was, to *turn over* the water from the copper at a boiling heat, and to wait till the steam was so far dissipated that the brewer could see his face in the liquor. This is still commonly practised in home-brewing, but in the large way the thermometer is now universally employed. It is impossible to give any fixed rules for the regulation of temperature in brewing, as it depends on so many circumstances, some of which must now be briefly noticed. The *kind of malt* is to be considered, as pale malt will bear a greater heat without setting than brown, though, according to Mr Combrune, the higher the temperature to which the malt has been exposed in the kiln, the hotter may be the water in which it is mashed. Well made malt, or that which contains least gluten, will also proportionally bear hotter water. The absolute quantity of malt used, and its proportion to the water, have an influence; when a large quantity of malt is employed at once, it, of course, keeps its heat longer, and the mashing water need not be so hot at first; and the greater the quantity of malt in proportion to the water, the more is the heat of the latter reduced on being mixed, and, of course, the hotter it ought to be when turned over. Brewers seldom employ a lower temperature than 145°, or a higher than 195°.

3. *Number of mashes.*—As all the virtues of the malt can scarcely be extracted by one infusion, it is usual to have two, three, and sometimes four mashings from the same quantity of malt. In this case, the first two or three worts are commonly mixed together for strong beer, and the last is kept apart for small or table beer. At least this is the case in domestic brewing, for in public breweries it is not allowable to brew strong and small beer from the same grist, without adding a portion of fresh malt for the latter. In conducting these several mashings, brewers proceed after the following method: Let us suppose that a hogshead of beer is to be made from a quarter or eight bushels of malt. About half the quantity of water is first turned over, and the malt mashed with it when it is of the proper temperature, say 175°; after mashing for about two hours, at first with agitation, and afterwards close and at rest, the tap is set, and the specific gravity of the first wort is taken by the saccharometer, which we shall suppose 1.104, or about 97 pounds per barrel on Thomson's saccharometer. The same quantity of water at a higher temperature, say 180°, is now turned over on the grains; and after mashing for an hour or two, this wort is found of the specific gravity, 1.040, or about 36 pounds per barrel. These two worts, after having been separately boiled, as will be immediately explained, are mixed together for the principal liquor; and, in the mean time, a fresh quantity of hot water, at a temperature nearly equal to the fresh liquor, say 160°, is added to the same grains for table-beer, or liquor for *finings*. While the saccharometer is used for taking the specific gravity of the several worts in the underback, the quantity of each in barrels is to be ascertained by the gauging-rod, and noted, that the necessary calculations may be afterwards made.

4. *Duration of the mashings.*—It is evident that the longer the mashing continues, provided the temperature of the liquor can be preserved, the more completely will the wort be saturated; but in large breweries, where dispatch is of great consequence, it is an object not to waste more time in any of the processes than is necessary. Two or three hours is generally allowed for the first mashing, and a longer or shorter time for the subsequent mashings, according to the quantity of malt, the heat of the liquor, and the purpose for which the latter worts are intended.

III. *Boiling.*—The wort obtained by mashing, the composition of which has been already described, has several deficiencies, which are to be supplied by boiling. It is not sufficiently concentrated; it abounds too much in gelatinous, or rather albuminous matter, which would render it thick and turbid; and it wants that bitter aromatic principle which is to improve its flavour and make it keep. The objects of boiling are to evaporate the superabundant water; to separate the coagulable matter; and to impregnate the liquor with the requisite principles. For this purpose, in domestic brewing, the worts that flow into the underback are put into the copper, and boiled for an hour or two, with a proportion of hops. In the large way, the wort is pumped up from the underback into the upper copper, or *copper-back*, to be kept warm by the steam of the liquor in the copper till this latter is emptied of its contents, when the wort from the copper-back is introduced, and the hops added to it. In the mean time, the subsequent wort, as it flows into the underback, is pumped up into the *copper-back*, and so on till the whole boiling be completed.

In the process of *boiling* two circumstances are chiefly to be considered, the quantity of hops, and the duration of the boiling. The proportion of hops varies according to the kind of liquor, the time it is intended to be kept, and the heat of the atmosphere at the time of brewing. The stronger the wort, the hotter the weather, and the longer the beer is to be kept, the greater is the proportion of hops employed. For strong porter, twelve pounds of hops to the quarter of malt is a good proportion; but if the fermentation is to take place in rather a high temperature, more will be required. For ordinary porter, seven pounds per quarter is sufficient. For ales, from four to eight pounds per quarter are employed in England; but in Scotland a much less proportion is often used. We are informed that in Edinburgh the usual proportion of hops for very strong ale is one pound to every bushel of malt, that is, eight pounds per quarter; and for mild ale, one pound to a bushel and half, or about five pounds per quarter. Where table beer is made from fresh malt, it is usual to allow three pounds of hops to the quarter of malt in winter, and six pounds per quarter in summer. It is of advantage to inclose the hops in a coarse canvas bag, so that they be tied loosely in it; and the bag should be frequently agitated in the liquor. Thus the wort is impregnated with the virtue of the hops, while the liquor is more easily examined, and more

Processes. easily separated from the hops. This method, however, can scarcely be practised in extensive breweries, where several hundred weight of hops are often thrown at once into the copper. Then a sort of drainer, called the *hopback*, is employed for straining the boiled wort clear from the hops. The same hops are boiled successively with each wort; but, in this case, the first wort receives the most delicate parts of the hop, and the last its coarser and most resinous parts. The hops, after being used in the copper, may be employed as manure; and we may here remark, that the *grains*, or draff, left after mashing, form an excellent food for hogs and cattle.

The boiling is to be continued for such a length of time as may be sufficient to separate the coagulable part of the wort, and impregnate it with a proper portion of the bitter and aromatic principles of the hop. Brewers form their judgment of the worts being properly boiled by examining a little from time to time, and observing whether the coagulable matter is separating from the wort in flocks, leaving the intermediate liquor clear. This commonly takes place in from one to four hours, and is more easily effected in the early than the subsequent worts. It is usual to boil the first wort for porter one hour, the second two, and the third three or four hours. For fine ales, such as *amber*, *Burton*, and the sweeter Scotch ales, from half an hour to an hour is sufficient. In making small beer from fresh malt, the first wort may be boiled half an hour, the second an hour or an hour and half, according to the heat of the weather, and the third two or three hours with the same consideration.

The effect of boiling, in concentrating the liquor, is often very considerable, so as to reduce twelve barrels of wort to about ten of beer; and the specific gravity is of course greatly increased. The quantity remaining is estimated by the gauging-rod, and its gravity by the saccharometer. As much liquor is retained by the hops, it is proper, when the last wort is strained, to subject these to pretty strong pressure, though this circumstance is not sufficiently regarded.

IV. *Cooling*.—When the worts have been sufficiently boiled and strained, they are introduced into the coolers. In domestic brewing this is a very simple operation, and is easily performed. The boiled liquor is poured by pailfuls from the copper into a basket set on two sticks over the cooler, and, while the hops are retained by the basket, the liquor is gradually diffused over the cooler, and is not long in acquiring the requisite diminution of temperature. In the large way, every method is taken to hasten this important process, as, if it be protracted beyond twelve hours, the liquor would almost certainly be *foxed*. The coolers are therefore of great extent in proportion to their depth, and are situated in the most airy and exposed part of the premises; and the liquor, when pumped up into them, is never, even in winter, suffered to stand more than five inches deep, and in summer not more than two or three. In summer it is of consequence to cool the liquor as much as possible; and for this purpose it is put into the cooler at the coldest time of the twenty-four hours, which is about three o'clock in the morning; but in winter any time of the day will answer. The degree of temperature to which the liquor must be reduced depends much upon the season. It must always be below 80°, and above 40°, as, at the former heat, fermentation would proceed too rapidly, and the liquor turn sour, while, at the latter, fermentation will scarcely take place at all. Combrune lays down the following rules for cooling malt liquors. In July and August, and in June and September, if the weather be not unusually cold, the liquor should be cooled as low as possible (provided it does not lie in the coolers above eleven hours); in May and October it should be cooled to about 60°; in April, November, and March, to about 70°; and in February and December it may be near 80°. Of course, in this variable climate, where the seasons so often interchange, some latitude must be allowed; and it is a safe plan to keep as near the medium heat of 60° as circumstances will permit, especially when we consider that the heat increases during fermentation. Processes.

When such a diminution of heat, from 212° to 60°, takes place, often pretty rapidly, and where such an extent of surface is exposed, a great evaporation must ensue. This is sometimes so great, where large quantities of liquor are cooled at once, as to reduce the liquor one-fourth. As the part dissipated is only water, the strength of the liquor is thus greatly increased, and this circumstance is to be taken into account in computing the quantity made. It now appears that several losses of fluid take place in the processes of brewing. First, there is a loss during mashing of the water retained in the grains. This is generally supplied by the sprinkling of fresh hot water while the *tap is spending*. Next there is a loss during boiling, which can be allowed for only by employing more water in mashing than amounts to the quantity of liquor to be brewed. Then, again, comes the loss by evaporation during cooling, for which allowance should have been made at the same time; so that, in brewing any precise quantity of beer, the brewer must be guided by experience what allowance he is to make on all these heads.

V. *Fermenting*.—The *must* being now prepared by mashing, boiling, and cooling, is to be subjected to that operation by which it is converted into a vinous liquor. The process of fermentation, which has already been described in the former part of this treatise, properly comprehends both what the brewers call *fermenting*, or *working*, and the next operation of *cleansing*, these being but steps of the same process; but in the practical part of our subject we shall treat of each under the technical term.

In the domestic process of fermenting, the liquor is *let down* from the cooler into one or two fermenting tubs as soon as it has descended to the proper temperature, and a proper quantity of good yeast is mixed with it. The whole is then stirred well together, and the agitation is repeated occasionally till the fermentation is fully begun, when the whole is left to rest. The first sign of fermentation having commenced is a white line appearing round the sides of the tub, and gradually spreading towards the centre. By degrees the whole surface of the liquor is covered with a white scum, which becomes more and more dense, till it thickens into a head, while

Processes. the singing noise and increased heat, which mark the progress of fermentation, soon after take place. The working commonly goes on for two or three days, or till the head of yeast begins to fall in the middle, when the liquor is tunned without the intermediate cleansing used in the public brewery. Here the liquor is conveyed by pipes from the coolers to the gyle-tuns, or *squares*, which are not nearly filled, that sufficient room may be left for working. The quantity of yeast that is mixed with the liquor to bring on the fermentation is various, depending on the heat of the weather, the strength of the wort, the kind of liquor to be produced, and especially on the quality of the yeast. In cold weather more yeast is required to begin the fermentation than in warm weather; strong wort requires more yeast than weak, as being less liable to fermentation; and *ale*, as being generally less fermented than porter, is worked with a smaller quantity of yeast. Above all things, the goodness of the yeast will determine the quantity employed; for when the yeast is old or weak, three times the usual proportion will scarcely produce the desired effect. In general, one gallon of good yeast is sufficient to ferment nine or ten barrels of moderately strong ale-wort; and from this it will be easy to regulate the proportion for other worts, and under particular circumstances.

6*th*, *Cleansing*.—Cleansing, as has been already mentioned, is merely the last stage of fermentation, and is intended to prevent this process from going on so rapidly, or to such a degree as to produce vinegar. It is effected by dividing the liquor in the gyle-tun into several smaller portions, by turning it over into the cleansing vats, and by this its temperature is diminished. These vats are filled to the very bung-holes; and the yeast, that is still formed on the surface of the liquor, runs off by the bung-hole into the vessels prepared to receive it. As the yeast flows out, it carries along with it part of the liquor, and this is continually supplied as long as the cleansing goes on. Were it not for this precaution, the yeast would not separate properly from the liquor, or this would not *purge* itself well. While the greater part of the yeast is flowing out at the bung-hole, another portion of greater density sinks to the bottom, constituting the dregs or *lees* of the beer. The time at which the operation of cleansing should be begun, it regulated by the subsiding of the head in the gyle-tun; and the time of its continuance depends on the heat of the weather, and the quality of the liquor. When the weather is warm, and the liquor weak, a very short cleansing is sufficient; indeed, small beer is seldom cleansed at all in the brewery, but is immediately put from the gyle-tun into the cask in which it is sent out to the consumer or the retail-dealer; and in Scotland is almost immediately transferred into bottles for use. The cleansing of *ale* is not continued so long as that of *porter*, and the fuller the body of each the more cleansing it requires.

In cleansing, it is of great consequence to supply the waste in the vats, occasioned by working, as speedily as possible, to prevent the yeast from forming an extensive head on the surface of the liquor. In most breweries this is done in the following manner. The cleansing vats, or casks, are laid upon their sides on stillions, with their bung-holes uppermost, and one of the workmen goes constantly round with a vessel of liquor from the gyle-tun to fill them up. As this would be extremely inconvenient in a large establishment, a method has been contrived in the London breweries for doing this in a mechanical manner. A vessel, called the *cleansing batch*, from which all the vats are filled by branches of the same pipe, is left with a certain quantity of liquor in it, and a small square cistern is placed beside the batch, and communicates with the same pipe from which the vats are filled, and this cistern also contains a quantity of liquor, on the surface of which there floats a hollow copper-ball, connected, by means of an iron-rod, with a valve at the bottom of the cleansing batch. This valve is opened by the copper-ball lowering as the liquor in the cistern is diminished, and thus allows the liquor to pass into the vats by the pipe till the surface of the liquor in the cistern again becomes so high as to close the valve by the rising of the ball. From the top of each cask at the bung-hole rises a tube about six inches high, with a spout to conduct the yeast into the receiver below; and by the contrivance above described, the liquor is made to stand at a certain height in the tubes, so as to insure the yeast's not mixing with the liquor in the barrel. Processes.

Another, and simpler method of cleansing, has been proposed by a late writer. His cleansing vats hold each about five barrels. A small hole is bored in the upper end of a stave, just below the head-hoop, and just under this hole is nailed a piece of leather to serve as a spout for carrying off the yeast. There is a bung-hole at the top of the cask, which during the cleansing is kept closed, and only opened every morning and evening to supply the waste. This method may do well enough in small breweries; but the mechanical contrivance above described is certainly superior, and answers the great object of this writer, preventing the access of external air quite as well.

7*th*, *Tunning*.—When the cleansing is completed, the liquor is ready for *tunning*, that is, putting it into those casks, or store-vats, in which it is to be kept till sold or used. The process of tunning in private brewing is very simple. The casks being properly scoured and freed from all unpleasant smell, are set upon the stillion in the cellar, either on one end or on their side, according to the fancy of the owner. They are filled from the fermenting-tubs by means of a funnel, formed of a small tub, with a metallic tube fixed in the middle of its bottom. The casks are filled as full as possible, and the bung-hole is left open, that any yeast which may form in consequence of the agitation of tunning may escape. When the bung-hole is pretty clear, it is closely stopped, and only a small hole called the *vent*, is either left open or loosely stopped by the *vent-peg*, till all danger of working, or of any great extrication of air, is over. The peg is then knocked in, and the liquor left to fine itself.

In the large breweries, the liquor, after cleansing, is pumped from the vats into enormous stone-cisterns, or wooden stores, containing, in general, many hundred barrels, where it is kept till sent out to the dealer.

Fining.—When beer is left to itself, it is generally a considerable time before it becomes transparent or fines itself. In domestic brewing this natural fining is always waited for, at the same time that the liquor is supposed to improve by long keeping; but in extensive establishments, where it is an object to have a quick return, the brewer fines his beer artificially. This is done by a liquor called *finings*, prepared by dissolving a quantity of isinglass in sour beer. A certain portion of finings is sent with the barrels to the innkeeper, who pours such a quantity into each barrel as experience has shewn to be sufficient for rendering the liquor transparent. The isinglass, from its glutinous property, entangles the flocculent particles that render the liquor opaque, and forms with them a filmy net-work, which, in the course of a few hours, sinks to the bottom. The particular mode of preparing finings varies among different brewers. According to Mr Morrice, as much isinglass is to be added to a cask half full of bright stale beer as will fill it. After standing for some time, and being stirred about frequently to promote the solution, the isinglass is strained through a coarse sieve over an empty cask; and those parts of it that will not pass the sieve, are returned to steep again; so that, by repeated strainings, nearly the whole is got through. The cask of strained liquor is now to be filled up with some sharper beer; and, after standing till the whole of the isinglass seems dissolved, the liquor is to be passed through a finer sieve into a clean cask, and is then fit for use. Ale finings require the finest isinglass, but for porter an inferior kind is employed.

Colouring.—It has been already observed that, finding it more economical to use pale malt, brewers have contrived to heighten the colour of their liquor artificially, and we believe the practice very good. The *colouring* is usually prepared from sugar, melted over a clear fire, and then inflamed, so as to burn for a few minutes, when it is extinguished, and a sufficient quantity of water added to reduce it to the consistence of treacle. Some brewers used to prepare the colouring from the richest of their wort, boiled down to the consistence of treacle, and then set on fire. The result is much the same in both cases. This colouring is sometimes put into the liquor before sending out, at others is mixed with the finings. The quantity of colouring depends on the intensity of colour required to be given, but the usual proportion is from two to three pounds per barrel.

It is proper to remark here, that, by a late alteration in the Excise laws, brewers are prohibited from making their own colouring, this being now the employment of a peculiar manufactory, yielding an addition to the revenue of ten shillings per barrel.

Having thus detailed the general operation of brewing malt liquors, as practised both in domestic and public brewing, we shall conclude this section with some remarks on the principal kinds of malt liquors, and their preparation.

Ale is the sweetest, lightest coloured, and, in general, the brightest of the malt liquors. It contains most undecomposed sugar, owing to its fermentation not having been carried to its utmost extent; and from its being brewed with a less proportion of hops, it has but little of the bitter flavour. Its strength varies exceedingly, being determined by the proportion of malt employed. When good, it is of a fine amber colour, as transparent as the finest wine, of an agreeable sweet but pungent taste, a slight bitter flavour, and not too frothy. The ales of particular districts, as Burton, Dorchester, Windsor, Edinburgh, are most prized in this country.

In brewing ale, the malt is either altogether pale, or pale malt mixed with a small proportion of amber, and hard water is generally preferred to soft. Supposing the proportions of malt and water to be one quarter of the former to three barrels of the latter, and the brewing to take place at the usual season, the process is generally as follows: The whole malt is first mashed, for about three quarters of an hour, with two barrels of water, at a temperature of 170°, or 180°; and, after standing an hour longer, this first wort is drawn off. One barrel of water, at the temperature of 180°, or 190°, is then added to the goods, mashed for three quarters of an hour, and, after standing about the same time, this second wort is drawn off. A third mashing for half an hour takes place, with a barrel of water at about 160°; and this wort, after standing quiet for half an hour, is drawn off, either to be kept separately for table-beer, or mixed and boiled with the two preceding worts. In general the two first worts are boiled, each for about an hour, with the usual proportion of hops, which is about eight pounds per quarter of malt, upon an average. The boiled worts are then cooled down to 65°, or 60°, and pitched for fermentation either separately or together, according to the object of the brewer. If the third wort is intended for table-beer, it is fermented separately, with the precaution already noticed under *fermentation*.

We know that good ale may be brewed from malt and hops alone, but in the receipts given in books of brewing several other substances are mentioned as ingredients; thus, Mr Morrice, in his receipt for London ale, mentions grains of paradise, coriander-seed, and orange-powder; for Wirtemberg ale he orders honey, sugar, hartshorn shavings, coriander, and carraway-seeds. There is good reason to believe that sugar is often added, and when malt is very dear this may be done with advantage.

Table and small-beer.—In domestic brewing, table and small-beer, which differ only in strength, are very commonly made from the wort produced by the last mashing, but in public breweries they are more commonly prepared from the first. The following is Mr Morrice's method of brewing table-beer. He uses eight quarters of malt, of which six are pale and two amber, seventy-two pounds of hops, and twelve pounds of Spanish liquorice, which we presume might as well be spared. He mashes three times, first with about fifteen barrels at about 168°, for three quarters of an hour; second, with the same quantity at 172°, for half an hour; thirdly, with twenty barrels, at 158°, for half an hour. He boils the first and second worts together with the hops, and the third worts separately with the same hops, and pitches

Processes. these worts mixed together at 70°. Other brewers, to make eight barrels of table-beer, use one quarter of malt, which they mash four times; *first*, with two barrels, at 170°, for about an hour; *second*, with one and a half barrels, at 145°, for half an hour; *third*, two barrels, at 165°, for half an hour; and, *fourth*, three barrels, at 180°. These worts are boiled successively for one, two, and three hours, with six pounds of hops, and set to work with about five pints of yeast to each quarter of malt, at the temperature of about 55°.

Beer and porter.—Beer differs from *ale* in being of a darker colour, and more bitter, and generally a sweeter taste. There are various kinds, as amber beer, or twopenny, entire butt, or common porter, and brown-stout. There is also a table-beer of this description. Formerly beer was brewed with a large proportion of brown malt, but at present less of this is employed, the deficiency being made up by colouring. As porter is most in request of all the varieties of beer, the following observations will relate chiefly to that liquor.

It is generally allowed that the porter of the present day is much inferior to what was brewed previous to the late war, and, though there is considerable difference of opinion with respect to the causes of this inferiority, it is attributed chiefly to the increased tax on malt. The best porter is of a full rich flavour, not too bitter, nor at all acid, of a moderately dark colour, so as to be easily seen through, and not carrying too large or dark a head. It is brewed in the following manner: Supposing 25 quarters of malt to be employed for brewing about 90 barrels of porter, the proportions usually employed are either equal parts of pale amber and brown malt, or from 9 to 13 quarters of pale, and from 8 to 6 quarters of amber, and the same quantity of brown. The proportion of hops for this quantity is 1½ cwt. and, according to Mr Morrice, some brewers use 30 lbs. of Leghorn liquorice, and from 4 to 6 lbs. of *cocculus indicus* berry. Nearly the whole of the malt is first mashed, with about half the quantity of water, heated to about 150°; and after the mashing has continued from three quarters of an hour to an hour, and the liquor has been suffered to remain on the goods for about an hour, the first wort is drawn off, and put into the copper-back, at the head of the great copper. In the mean time, the second liquor, to the extent of about 36 barrels, has been heating to 160°; and after mashing with this half an hour or three quarters, and standing an hour, this second wort is drawn off. During this second mashing, the first wort has been boiling in the copper with the hops for an hour, while the third quantity of water, equal to the second, has been heating in the copper-back, and is afterwards let down into the copper till it acquires the heat of about 180°. The second wort being pumped into the copper-back, the third mashing takes place for about half an hour; and after the liquor has stood for about an hour, it is drawn off. The second wort is boiled for two, and the third for four hours. When liquorice is used, it is generally put into the copper, and dissolved in the second wort. All the worts are now mixed together, after being cooled to about 60°, and yeast in the proportion of five English pints to each quarter of malt is added. The fermentation in the gyle-tun continues for a day or two according to circumstances, and is then checked by cleansing. Some brewers mash each kind of malt separately.

Brown stout is a stronger kind of porter, requiring, of course, a greater proportion of malt and hops. The following is Mr Morrice's method of brewing it. He uses 20 quarters of malt, of which twelve are brown, four amber, and four pale, two cwt. of hops, with 28 lbs. of sugar, 14 lbs. of Spanish juice, four lbs. of *cocculus indicus*, and six lbs. of *faba amara*. It is presumed that the two latter may be omitted, and their place supplied by a greater proportion of malt and hops. The malt is first mashed with about 30 barrels, at 168°, for one hour and a half, and the liquor stands an equal time upon the goods. The second mashing takes place, with about the same quantity of water, at 174°, mashed for one hour, and standing an hour and a quarter. The first wort is boiled for two hours very briskly, putting in the *drugs* about a quarter of an hour before the boiling is finished. The second wort may be boiled three or four hours; and when the two are mixed together, there should be about 50 barrels. The liquor is cooled down to 66°, and set to work with a gallon of good yeast. Cleansing takes place the second day after brewing, when half a pound of salt and a little flour is added.

Mr Morrice recommends a quarter of fresh amber malt to be added to the grains, and table beer to be brewed, with 50 barrels of water, at 170°, mashed for an hour and a quarter, and standing as long upon the goods; the liquor to be boiled with the old hops, proceeding afterwards as before directed.

There is a kind of beer similar to porter, but brewed from *pale* malt, called *hock*, which is brewed with water at a higher temperature, and mashed for a longer time. This liquor is used chiefly to mix with other porter, to give it a peculiar strength or flavour. It may be here remarked, that though porter is called *entire butt*, from the idea that it all comes from one cask, it is the custom of porter-dealers to mix two or more kinds together, so as to suit the palate of their customers, some of whom prefer a mild, and others a hard porter. It is, therefore, common for the brewer to send a barrel of stale porter for every three or four of mild; and where draught porter is in request, both these kinds are tapped at once, and mixed by the drawer in the proportions required.

Amber beer, or twopenny, is prepared with about three parts of pale malt and two of amber, in the proportion of 25 quarters of malt and one cwt. of hops to about 80 barrels, adding, according to Mr Morrice, 30 lbs. of treacle, 20 lbs. of Spanish juice, with a proper quantity of *grains of paradise*, and *faba amara*.

SECT. II. *Of Beers made from Sugar.*

Of beers made from sugar, we shall particularly notice only three.

1*st*, *Treacle beer*.—A very pleasant beer, fit for family use, is made from treacle in the following manner. About five lbs. (or more, according to the strength required,) of treacle or molasses are dissolved in a sufficient quantity of hot water, while an ounce or two of good hops are boiled for a few minutes in about a quart of water, and the liquor strained. These two liquors are mixed together, and the quantity made up with warm water to about eight English gallons. When the mixture is reduced to a proper temperature, between 60° and 80°, a piece of toasted bread, well spread with good yeast, is put in, and the liquor left to ferment for two or three days, when it is turned into a cask, or bottled up for use. The quantity here directed will fill about three dozen bottles.

In fermenting liquors made from sugar, or the juices of fruits, the head of yeast is proportionally thinner, and less irregular, than that on the surface of malt liquors.

2d, Spruce beer may be prepared by adding to the above solution of treacle, before it be set to work, a 3s. 6d. pot of essence of spruce. The following is the receipt of a late writer for preparing spruce beer. Ten English gallons of water are boiled, and allowed to stand all night in a clean tub. In the morning, ten pounds of treacle are dissolved in a sufficient quantity of water, in a brass pan, over a clear fire. In this solution of treacle, a 3s. 6d. pot of essence of spruce is added, and after mixing well together, the whole is put into a ten gallon cask, with about half the boiled water, and an English pint of good yeast. The cask is them well shaken, and filled with the rest of the boiled water. After standing to ferment for two or three days with the bung open, filling it up occasionally with boiled water, the cask is bunged up for about a week, after which it is fit for bottling.

3d, Ginge rbeer.—Ginger beer forms a very pleasant and wholesome beverage in warm weather. It may be prepared in the following manner. Boil as much water as will fill a ten gallon cask, and let it stand all night. Dissolve ten pounds of lump-sugar in a brass pan with a sufficient quantity of water; and if the sugar be coarse, add the whites of two or three eggs to clarify it. When the liquor is freed from scum, add the paring of six lemons, and the liquor obtained by steeping half a pound of bruised ginger in a quart of warm water for a night. Boil these together for about twenty minutes, and put them into the cask with the juice of six lemons, a pint of good yeast, and about half the boiled water. The cask is then well shaken, filled with the rest of the water, and left to work for two or three days, filling it up occasionally. After this it is bottled and set in a cool place, and will be fit for use in about ten or twelve days.

SECT. III. *Of Wines.*

1st, OF WINES FROM THE JUICE OF THE GRAPE.—Notwithstanding the great variety of these wines, the general process for preparing them is much the same in all. The grapes are gathered when they have arrived at such a state of maturity as the nature of the proposed wine requires. For the rich, luscious, or very strong wines, such as Malmsey or Madeira, the grapes are not only suffered to hang till they are perfectly ripe, but are half dried upon the vine, by partially dividing the stalk, and thus preventing the flow of sap, while the heat of the sun exhales part of the water in the juice, leaving the rest in a concentrated state. For the drier and weaker wines, the grapes are gathered earlier, and in a more succulent state. In expressing the juice, regard is also had to the nature of the wine. For some that are intended to be austere, as port and claret, the stalks are pressed together with the grapes; for others, the fruit is carefully separated. They are generally first trodden by several men with wooden shoes, and then the juice is squeezed out by means of a strong screw. The expressed juice is sometimes suffered to stand several hours mixed with the husks; and for the darker wines, it is set to ferment under the same circumstances. The fermentation of the juice is continued, from a few hours to several days, according to the heat of the weather, or of the room where the process is conducted, and the nature of the grape, some kinds requiring a longer fermentation than others. The weak sweet wines are fermented less than the full bodied stronger wines, but those which are dry and sharp, as Hock and Rhenish have undergone the greatest degree of fermentation. During this process, where the husks are put into the fermenting vats, they form a solid cake on the surface of the liquor which remains tolerably clear below, but further purifies itself after being tunned into the casks in which it is to be kept. A perfect state of fermentation requires a proper regulation of the heat, and the addition of sugar, or of must, concentrated by boiling where the juice is too watery.

After the wine is put into the casks, it gradually diminishes in quantity, owing as is supposed to the wood of the cask imbibing part of its water, as it is observed that it grows stronger by keeping. It is necessary, however, to supply the waste and keep the casks full, and care is taken to fill them up with wine of the same quality. It is usual to add a quantity of brandy to the wine when tunned, and in some wines, especially port, the proportion of brandy is very considerable. The casks are kept in cool cellars, made as dark as possible, that the wine may not be rendered sour by the rays of the sun.

The fermentation of the must, when it is likely to proceed too far, and cannot be sufficiently checked by racking into fresh casks, is effectually impeded by what is called sulphuring. In the simplest form of this process, matches tipped with sulphur are introduced into a clean empty cask, set on fire, and suffered to burn as long as the air in the cask will support combustion. Thus the cask is filled with that peculiar gas called sulphurous acid, and while in this state the wine is racked into it, and shaken so as to be impregnated with this gas.

Many foreign wines, especially the white, are nothing but the juice of the grape properly fermented; but others owe their *strength* to a mixture of sugar or brandy; their *flavour* to the addition of aromatic, vegetable, or essential oils, and their colour to various colouring materials, as logwood, red sanders, oak-chips, cochineal, &c. added during the fermentation, as well as to allowing the husks to steep or ferment in the juice; or their colour is heightened by the addition of a very dark wine called *Vino-Tinto.* Indeed, several of these wines, as port and claret, are made *up*, as it is termed, of two or more wines; and this making up is effected, by mixing them while one or both is in a state of partial fermentation, when, by *fretting* together, the mixture is rendered more homogeneous and complete.

Defects of wines.—Wines are subject to certain defects or diseases, as they have been termed, which require notice. Weak and thin wines are liable to *fretting*, that is, renewed fermentation, which, if not checked by sulphuring, is best removed by the salt called *sulphite of potass*, in the proportion of a drachm to each pipe. *Acidity* in wine, arising from over fermentation, is not easily removed, though for this purpose lead in various forms has been employed, but as this is a dangerous practice, chalk is to be preferred. *Turbidity* is removed by clarifying, as will be presently described. The other defects are chiefly *ropiness* and *mustiness*, the former of which is counteracted, by exposing the bottles to air and sunshine, by agitation, the addition of a little vegetable acid, and clarifying, and the latter may be diminished by pumping in contact with carbonic acid.

Red wines.—In the table given at p. 5, only seven red wines are enumerated, not because these are *all* the red wines known, for there are many red wines having the same denomination as the white, as *Champagne*, *Frontignac*, &c. Those in the table, however, are the principal. Of these, *Tokay* is a wine of Upper Hungary, so called from a mountain, otherwise denominated *Hegy-alya*, on which the finest vines are produced. It is peculiarly rich, keeps well, and is very wholesome. It has been called *imperial*, from an idea that it is reserved for the Emperor's use; but it is made in considerable quantity, and is drunk by the wealthy in every country, especially Russia. *Burgundy* is the richest of the French red wines, and, is made chiefly in the upper province of that name. It is prepared with the greatest attention from select grapes, and under the superintendence of the magistrates of the district. This wine keeps well, and though very generous, does not contain a large proportion of ardent spirit. *Lacryma Christi* is an Italian wine, made in the kingdom of Naples, and is fat, sweet, and of a grateful pungency. *Red Port* receives its name from Oporto in Portugal, where it is usually shipped to this country. It is the strongest of all the red wines, from the large proportion of brandy mixed with it, but it is also one of the wholesomest from its astringency. The must from which this wine is made is completely fermented in the vat, and then the liquor is transferred into large tuns, containing each twenty-five pipes, and at this time the brandy is added. There is a red *Lisbon* wine similar to port, but richer and of a deeper colour. *Claret* is of a lighter body than port, but proportionally more astringent. It is made in several provinces of France, especially Bourdeaux and Guienne, though the claret of the latter is of an inferior quality. This wine, at least as we generally meet with it, appears to contain some acid. *Hermitage* is similar to claret, but much stronger, more generous, and less acid. It is made in the Northern provinces of France, especially Picardy. *Tent* is a Spanish wine, sweet and pleasant, but not very strong; it is made chiefly in the provinces of Andalusia and Gallicia. It is now in less demand than formerly, and is used chiefly at sacramental tables in cathedrals.

White wines.—Among the white wines, *Champagne* holds a high rank, not so much for its strength, as it contains less alcohol than most of the white wines, as for its briskness, pungency, and flavour. It is made chiefly in the French province from which it takes its name, and in order to secure its briskness, which is owing to the quantity of carbonic acid gas which it contains, it is bottled while yet in a state of partial fermentation. Hence, when the cork is withdrawn it mantles, but is not considered good if the bubbles of air stand long upon its surface. Considerable nicety is observed in the making of Champagne. The must is suffered to ferment in the vat for only one night, after which it is transferred into casks which are kept full, with the bung hole open for ten or twelve days, when the bung is driven close, but a vent hole left, and opened occasionally to discharge the superabundant carbonic acid. This is done for eight or ten days, when the cask is filled up with fresh wine, which is repeated once a week for about a month, and then once a month till the wine becomes clear. It is then transferred into a fresh cask, clear from the lees, and fined with isinglass; but if the wine shall prove too sweet, a fresh fermentation is first excited by rolling the cask, and thus mixing the lees with the wine. After standing in the new cask for about six weeks, it is again transferred clear from the lees, again refined, and in the month of March in clear dry weather it is bottled. About eighteen months after first bottling, the corks are drawn, and the wine decanted into fresh bottles soon after which it is fit for the market.—*Madeira*, so called from the island of that name, when genuine, is of the colour of fine Florence oil, and adheres to the glass, which it tinges with a light-bluish hue, and it has a kernelly taste, approaching to that of walnuts. Like other strong wines, it is prepared from grapes that have hung till they are perfectly ripe, and begun to dry, and a portion of brandy is added to the must before fermenting. It is repeatedly racked at intervals of a month or two, till March, fresh brandy being added at each racking, and it is then bottled for use. *Teneriffe*, is a Spanish wine, made in the island whose name it bears, and much resembles Madeira, except that it is weaker, and less unctuous. The wine called *Vidonia* is a variety of Teneriffe, made from a grape of that name. *Malmsey* is the richest of all the white wines, has a sweet taste, and a golden or brownish-yellow colour. It was formerly prepared only in the Grecian islands, but is now brought chiefly from those of Spain and Portugal. Thus there is a Canary Malmsey and a Teneriffe Malmsey; but that most in estimation is called Madeira Malmsey. *Sherry* is a Spanish wine, of a drier quality, and containing more brandy than those above-mentioned, and receives its name from the town of Xeres. In its preparation the grapes are sprinkled with slaked lime, and brandy is added before fermentation. *White Port* differs from red port only in colour, owing to the juice not fermenting on the husks. It is a wholesome, not unpleasant wine, consumed chiefly in Portugal. *Lisbon* is a pleasant wine, similar to sherry, Processes, but weaker. *Constantia* comes from the Cape of Good Hope and is made at the village of Constantia from a species of Muscada grape. It is of exquisite flavour, and prepared with the greatest care. There are two varieties, white and red. The wine called *Cape*, or *Cape Madeira*, is a dry and rather harsh wine, brought from the same part of Africa. *Hock* and *Rhenish* are German wines, both dry, but the former is much stronger than the latter, and takes its name from the village of Hockheim, upon the Rhine. These wines appear to owe their sharpness to a quantity of malic acid. The best hock, commonly called Old Hock, is reckoned very salubrious, being less heating, though more exhilirating than many weaker wines. *Mountain*, sometimes called *Mountain Malaga*, is a rich sweet wine, brought from the south of Spain. There are two varieties, the dry or well fermented, and the sweet or luscious. *Calcavello*, or *Carcavella* is a Portugal wine, very similar to dry Mountain, but weaker, and now in little request. *Frontignac* is a sweet, high-flavoured, French wine, made from the grapes of that name.

After this concise account of foreign wines, we proceed to the preparation of those called *Domestic*, among which is reckoned the *British grape wine*. This, as we shall presently see, might be brought to considerable perfection, even in our northern climate.

2d, Of wines from other fruits.—The manufacture of home-made wines, or *sweets*, is now carried on in this country to a considerable extent, though still capable of great improvement. Attempts have been made to imitate the foreign wines, and we continually see British port, sherry, champagne, &c. advertised by the dealers in made wines. Now, though these attempts have in many instances proved abortive, there seems no doubt that wines of a very superior quality to those commonly sold may be manufactured in this country. The chief defects of our ordinary domestic wines are, that they are either too sweet, from containing too much undecomposed sugar, or so thin as easily to become sour, that they have either no flavour, or have a disagreeable taste and smell, from the nature of the matter by which they are fermented. As it is agreed that the foreign wines from the juice of the grape are decidedly superior to all other, it is evident, that the nearer our wines can be made to approximate to those, the better must be their quality. Now, we know that the principal ingredients in the juice of the grape are, *water*, *sugar*, *tartar*, and *vegetable extractive*, and that the fruits of this country, if we except the grape, are deficient in the second and third of these principles, while they contain, in many instances, an excess of *malic acid*. The great object, then, in making British wines is, to supply the saccharine and tartarous principles, and so to manage the fermentation as at least to avoid unpleasant flavour; and where a dry wine is required, to decompose as much as necessary of the sugar. The concrete juice of the sugar cane, and in a few instances molasses or honey, are the saccharine substitutes employed in addition to the juice of our native fruits. The tartar commonly called crude, or unpurified, as it is collected from the casks of foreign wine, is preferable to the purified chrystals, or cream of tartar, as the former contains, in a dry state, a portion of that vegetable extractive which is necessary to insure the fermentation of the sugar. Many of our domestic wine-makers employ the yeast from malt liquors in fermenting their must; but this practice is highly exceptionable, as it gives to the liquor a bitter taste and unpleasant odour. Processes.

The processes of making domestic wines consist chiefly of *preparing the must*, *fermenting*, *racking*, *clarifying*, and *bottling*.

The *must* for these wines must be regarded as altogether artificial, being made up of the juices of fruits mixed with sugar and tartar. The manufacturers of these wines for sale are accustomed to prepare a fundamental sweet, from which, by the addition of certain colouring and flavouring substances, they afterwards produce the particular wines. This fundamental must is generally made from raisins, sugar, or molasses, or honey, water, and tartar; the molasses being used when a dark wine is required, and the sugar for white wines. For domestic purposes, it is better to employ sugar, in the proportion of two, three, or four pounds to each gallon of fluid, according to the proposed strength of the wine; and this fluid should consist, as far as possible, of the juice of some native fruit, observing that the riper and sweeter the fruit, the greater may be the proportion of its juice; for though unripe or acid fruits will make good wine with a sufficient quantity of sugar, the strong acids in those requires dilution before a perfect vinous liquor can be formed. The proportion of tartar should vary according to the deficiency of it, and the degree of sweetness in the fruit used; but in general from two to four lb. per cwt. will be a good proportion. In some cases no fermenting matter but that contained in the tartar and the fruit, is necessary, but in others it may be proper to introduce an additional vegetable extract, and it has been found that vine leaves answer this purpose extremely well; though if the scum or lees of former brewings of the same wine can be procured, these constitute the most advantageous ferments.

Fermenting.—There are some niceties in the fermentation of this *artificial* must which require notice, in *addition* to what has been observed under foreign wines. Where a still wine is to be produced, the fermentation may be carried on in comparatively open vessels; but when a brisk wine, in imitation of Champagne, is to be the result, the vessels should be as close as possible, consistently with their safety. When any peculiar flavour is to be imparted, as that of raspberries, cowslip, elder-flower, &c. it is of advantage to introduce these substances towards the end of the first fermentation, or during the second, which usually takes place on the return of warm weather; thus a smaller quantity of the flavouring matter is required, and a fuller and more delicate flavour secured.

Racking.—The operation of racking in wines may be said to comprehend both the cleansing and tunning employed in malt liquors. When the fermentation is to be checked, the liquor is transferred from the fermenting vat or cask into a fresh cask, and when effectual means are to be taken to prevent further fermentation, this cask is sulphured. Racking is also employed for decanting the wine from its lees, which is done either by means of a syphon, or by compressing the air in the full cask, by the following simple contrivance. A flexible tube covered with leather is fixed at one extremity to the cock of the full cask, and at the other to the bung-hole of an empty one. A pair of bellows is now fitted so as to be air tight to the bung-hole of the full cask, and by its continued action, such a quantity of air is impelled as forces the wine out by the top of the tube into the empty barrel, so as not to disturb the lees.

Clarifying.—As all wines take a considerable time to become clear, it is found convenient to hasten their clarification artificially. This may be done either by whites of eggs or isinglass, in the proportion of about 18 of the former, or 1 oz. of the latter, to 100 gallons of wine. The clarifying substance is mixed or dissolved in a small portion of the wine, and then incorporated with the rest in the cask by stirring.

Bottling.—Wines should be bottled in the spring before the subsequent fermentation, which usually takes place at that season, has proceeded too far. For this process, clear dry weather should be chosen, as the wine is then in its clearest state; and the same caution will apply to racking. It is common with the dealers in made wines to use inferior and shorter corks, but it is not easy to explain why the corking of these wines should be more negligently performed than those of foreign countries, which are not so liable to injury from this neglect. It is usual to introduce a raisin or a small piece of sugar into each bottle for the wine to feed on, that is, to keep up an insensible fermentation, which prevents the wine from growing sour.

It is common in making domestic wines to add a portion of *ardent spirit* before bottling, a practice which, to say the best of it, is useless. It indeed checks fermentation, but it renders the wine flat and heating. If any such addition be necessary, it should be made before the fermentation has proceeded too far.

Cleaning of casks, &c.—In the preparation of wines, equally with that of malt liquors, the greatest attention should be paid to the cleaning all the utensils employed, especially casks and bottles. In ordinary cases casks are easily cleaned by scalding them with hot water, and when new this is all that is necessary, but old casks are apt to contract a musty smell, or become decayed in the inside. The former defect is removed by slaking lime in them, and afterwards scrubbing and washing them, but the latter is best removed by the aid of the cooper.

Particular domestic wines.—Instead of giving many receipts for the individual domestic wines in this treatise, we shall make a few remarks on each, and point out the general procedure as exemplified in one or two kinds.

Currant wine.—Good wine may be made from each variety of currant, and that either ripe or unripe, the former making a still, the latter, if properly managed, a brisk wine. Forty lbs. of the *unripe* fruit, picked carefully from the stalk, are to be bruised in a tub capable of holding 15 or 20 gallons, so as not to break the seeds; four gallons of water are then to be added, and the whole well mixed and squeezed together with the hand, till the juice and pulp are separated from the husks and seeds. The whole is to remain at rest for a period from 6 to 24 hours, when it is strained with moderate pressure through a coarse flannel bag, adding about a gallon more water to the *mare,* and again pressing out the juice. Thirty pounds of white sugar are dissolved in the liquor, and the whole is made up with water to 10½ gallons, so as to fill a 10 gallon cask. It is set to ferment in a tub covered with a blanket and board, and after remaining a day or two according to the weather and the degree of fermentation, is to be racked into the cask, and treated as already generally described. For *ripe* currant wine, from 40 to 60 lbs. of fruit, according as the wine is to be sweet or dry, are used to 30 or 40 lbs of sugar, and about six ounces of crude tartar in powder are added to the expressed liquor; but little or no water should be employed. Black currants require to be brought to the boiling point with a sufficient quantity of water to prevent burning. *Grape.*—Grapes, like currants, may be employed either in the ripe or unripe state, and the process is much the same as above described, except that, (when unripe,) the whole bunch may be bruised together, and that no tartar is required; but as the fermentation is generally slow, it must be watched with patience, and increased by occasional agitation, without filling up too often. When the grapes are ripe the stalks must be left out, and no water used; and the proportion of sugar should be 1 or 2 lbs. per gal. according to the ripeness of the fruit. In this way, British grape wine may be made equal to Cape. Wine has even been prepared in this country from grape leaves and tendrils, especially those of the claret grape, using 40 or 50 lbs of leaves, infused for 24 hours in seven or eight gallons of boiling water, and dissolving in the expressed liquor 25 to 30 lbs of sugar, or more, if a dry still wine be required. *Gooseberry* wine is prepared from either ripe or unripe fruit, in the manner directed for currants, except that greater care must be taken to separate the skins from the *must,* more especially in their *ripe* state, as they impart to it an unpleasant flavour. Wine from unripe gooseberries resembles Champagne, and has been called *British Champagne.* *Cherries* make an agreeable wine, if care be taken not to break many of the stones, which impart too strong a bitter flavour. From *damsons,* and still more from *sloes,* may be made a rough wine, of good quality, which, by a mixture of currant wine, made up as formerly directed, resembles port. The *elderberry* produces an excellent red wine; but being deficient both in acid and sugar, requires the addition of this latter, and of tartar in considerable quantity. The berries should be brought to a boiling heat before expression. *Oranges* and *lemons* possessing an excess of citric acid, do not readily form a good wine, and the liquor commonly made from them is both too sweet and has too much flavour of the peel. These should be made in small quantities of two gallons or so. *Strawberries* impart little to a vinous fluid but their juice; and *raspberries* are best applied in the form of syrup, to give an agreeable flavour to *currant* and similar wines.

Processes.

Quinces, apples and *pears*, from containing so much malic acid, form vinous liquors of a peculiar nature. Quinces also possess a degree of acerbity which produces a rough wine, and, indeed, are seldom employed for that purpose. *Cyder* and *perry*, the vinous liquors resulting from the fermentation of apple and pear juice, are prepared in a similar manner. The fruit reduced to *pommage*, in the manner already described at pages 10 and 11, is expressed, and set to ferment at the temperature of about 50°, either in a vat closely covered, or in a cask, where it is suffered to remain till it becomes tolerably clear, and has acquired the vinous flavour. It is then transferred into a fresh cask, and exposed for a day or two in a cool situation. It is then racked into another clean cask, where it remains for the winter, unless a fresh fermentation takes place, discovered by a hissing noise, in which case it is again racked; and this operation is repeated when necessary, till March, when the liquor is transferred into bottles, or the vessels into which it is to be kept for use. The casks are filled up from time to time as the liquor wastes, and when bottled the corks are secured with twine or wire, to prevent being driven out by the air which is still produced. Good perry resembles French Champagne even more than the wine from unripe gooseberries, and, if we are rightly informed, has not unfrequently been sold for that expensive wine.

Raisin wine differs from the rest of our domestic wines in being prepared from a dry fruit, which contains little more than the saccharine principle of the grape, with perhaps a little astringency from the skins. The usual proportions for making this wine are, from two to seven pounds of raisins, and from half a pound to three or four pounds of sugar to the gallon of water. The raisins are cut, and sometimes boiled with the water, or steeped in it at a boiling heat. A quantity of tartar may also be added, and the liquor is usually fermented with the raisins, and afterwards squeezed out by pretty strong pressure.

The following receipt for making an excellent raisin wine has been communicated by a friend: Take to each gallon of water seven pounds of Malaga raisins, pick them from the stalks and chop them; put in half the quantity of water boiling hot, and let it stand three hours; run this off, pour on the remainder of the water, and let stand for a night; then run it off, and press the raisins as dry as possible. Put the whole into a cask, and, when it has done fermenting, stop it up for six months, *i. e.* if the wine be made in March or April, which is the best time, let it stand till October, then rack it off. If the thick part at the bottom of the cask be distilled, and the spirit be added to the must, it will improve the wine, and nothing will be lost.

3d, Of wines from sugar.—Of the wines enumerated in the table, page 5, as made from sugar, the first five consist of a simple vinous liquor, flavoured with the several substances from which they take their name. *Ginger* wine, according to the usual process, is, indeed, little else than toddy impregnated with ginger, as, from the quantity of spirit employed, the liquor can be scarcely said to be fermented. The best porportions are 30 lbs. of sugar, and 6 oz. of sliced ginger, boiled for a few minutes in 8 gallons of water, and when the liquor is near cold a pint of lemon juice, and the rinds of 6 or 8 lemons are added, and a sufficient quantity of lees, or scum of wine, to produce fermentation, and when this has continued two days, the liquor is put into a cask, with about two quarts of ardent spirit. For *cowslip wine*, a must is prepared with 3 or 4 lbs. of sugar to each gallon of water, and when the fermentation has proceeded sufficiently, some *cowslip* flowers, lemon-juice, and a little lemon-peel, are added. *Clarey*, *baum*, and *elder-flower* wines, are prepared in a similar mannar.

Birch, *palm*, and *parsnip* wines, are made from the juices of these vegetables, boiled with a sufficient quantity of sugar, the ordinary proportion of which is 2 lbs. to every gallon of juice, and fermented in the usual way; the fermentation is continued for a day or two, when the liquor is racked into a fresh cask, prepared with sulphur to check excessive fermentation. After standing for about three quarters of a year close stopped in the cask, it is bottled.

The vinous liquor called *Mead*, or *Metheglin*, when properly prepared, and suffered to stand for a sufficient time, much resembles *Mountain Malaga*. There are several varieties of mead, both simple and compound, the former being prepared with honey and water only, the latter with a mixture of other fruits, especially raisins, raspberries, and currants, and it is commonly flavoured with elder-flowers, or other aromatic plants. Several receipts have been given for making mead, but that of Mr Huish, as given in his late work on Bees, appears to be the best. His proportions are thirty pounds of honey to about nine gallons of water, which are boiled together till one half is reduced. He then puts two thirds of this liquor into a clean cask, rinsed with brandy, and the remainder into bottles, which are tied over with muslin. This bottled liquor is reserved for filling up the cask. The cask is set in such a heat as is sufficient to produce fermentation, which may be either that of a warm room or sunshine, and it is suffered to stand for about two months, filling it up from time to time, as the liquor wastes. When the fermentation has ceased, the bung is driven in, and the cask set in a cool place, where it should stand for two or three years before it be fit for bottling. Mr Shannon recommends the addition of tartar, in the proportion of four pounds to the hundred weight of honey.

To render mead purer, by abstracting from the must its peculiar honey flavour, and any acidity it may have contracted, Mr Huish advises to boil in the liquor first some chalk, and then some charcoal, each for about two minutes; and he clarifies the liquor, before fermentation, with the white of eggs. The clarification, however, would be better effected in the usual manner, with isinglass, after fermentation.

The consumption of mead in this country is now but trifling; but in some of the northern countries of Europe, especially Russia and Poland, where bees are very common in the wild state, it is the ordinary beverage of the people; though, from Mr Huish's account of its preparation there, it must be a most impure and naueous liquor.

BRIAREUS, in the mythological history of the ancients, a giant, the son of Æther, Titan, or Cœlus and Terra, and called on earth *Ægeon*, was at first serviceable to Jupiter, when Juno, Pallas, Neptune, and some of the other gods, conspired against his authority, and attempted to dethrone him; but he afterwards united with his gigantic associates for the same rebellious purpose; and as a punishment he was buried under Mount Ætna, which, according to the fable, throws out fire and smoke as often as he moves. Virgil represents Briareus with 100 hands, 50 heads, and breathing out fire.

BRIBERY, from the French word *bribe*, which, in its original meaning, signifies a piece of bread, or fragment of food taken off the table, denotes a reward which is given for the purpose of biassing the person who receives it in the discharge of a public duty. The term bribery, in a more enlarged sense, has been sometimes applied to undue influence in private transactions, but in general it is restricted to the effects of rewards, or the promise of rewards, to persons in public official situations, and particularly to those who are engaged in the administration of justice. By the law of England, bribery is punished, in the case of judges and officers of the crown, with forfeiture of treble the amount of the bribe, chastisement at the king's pleasure, and dismissal from office for ever; and on inferior officers the punishment is fine and imprisonment. By the law of Scotland, the offence of bribery, in judges of the supreme court, is punished with infamy, loss of office, confiscation of moveables, and discretionary punishment in the person of the offender; and in inferior judges and other persons it is punished with loss of fame and office, reparation of damages, payment of the parties costs, and discretionary censure, according to the nature and extent of the crime. In most countries where bribery is regarded as an offence, and a subject of punishment, the person who gives is considered as equally guilty with him who receives, and is exposed to the same penalties.—Blackstone's *Commentaries*, and Hume on *Crimes*.

BRICK, an artificial stone, composed of clay formed in moulds, and either dried in the sun, or baked or burnt in a kiln, for the purpose of building. In those parts of the world where stone is scarce, or the art of cutting it into proper forms is little known, the use of bricks is very extensive. In the earliest periods of society of which any record is preserved, bricks formed the materials of all buildings which were intended to be of a durable nature. They are alluded to in scripture history; one of the pyramids of Egypt is constructed of these materials; and the chief edifices of the Babylonians, the Greeks, and the Romans, in the early part of their history, were constructed of bricks. See Pottery.

BRIDGE, a structure of wood, stone, or iron, for the purpose of forming a convenient communication between the opposite banks of rivers. For the principles of construction, and for an account of some remarkable bridges, see Architecture.

BRIDGEND, a town of Glamorganshire in South Wales, stands on the opposite banks of the river Ogmore, and between which a communication is formed by means of a good bridge. The remains of ancient castles are still to be seen, and give name to some divisions of the town. The surrounding district is fertile and well cultivated, and the river abounds with salmon, trout, and other fish. The population is about 2000; and the manufacture of blankets and other woollen stuffs, by means of machinery, is considerable.

BRIDGENORTH, a town of the county of Salop in England, which is divided into the upper and lower town by the river Severn, on whose banks it is situated. The upper town occupies the summit and declivity of a hill, and consists chiefly of two spacious streets, from which others pass off towards the river, the bank of which is so steep that the passage is formed by flights of steps. Some of the houses are entirely excavated out of the sand-stone rock. The ruinous remains of walls, and a castle, indicate that it was once a place of some strength. A square tower of the castle, which, it is said, was undermined during the civil wars between Charles I. and the parliament, deviates, in a height of 70 feet, more than 20 from a perpendicular line.

The population is about 5000, and a large proportion of the inhabitants is engaged in the manufacture of leather, carpets, stockings, and hardware, in a cast-iron foundery, and in the building of barges for the navigation of the Severn. Placed in a central situation, in a rich country, Bridgenorth enjoys a considerable trade, which is greatly facilitated by water-carriage. The view from Bridgenorth, particularly from the elevated site of the castle, round which a fine terrace has been formed for the accommodation of the inhabitants, commands one of the finest and richly-wooded prospects of the western districts of England.

BRIDGETOWN, the capital of the island of Barbadoes in the West Indies, stands on Carlisle bay, in the south-west part of the island. Before it suffered from the destructive ravages of hurricanes and fires, Bridgetown was considered the most elegant town in the West Indies, and afforded almost all the conveniences and amusements of European cities. The streets are spacious, and the houses are lofty and well built. The church is a magnificent structure, furnished with a peal of bells, a clock of curious workmanship, and an excellent organ. Bridgetown has the advantage of a free school for the education of poor boys, and an hospital. The college, liberally endowed by Colonel Codrington, for maintaining professors and scholars to teach and study divinity, surgery, and physic, is the only institution of the kind in the West Indies. This college is, by the will of the founder, under the superintendence of the Society for the Propagation of the Gospel in Foreign Parts; and in the reports, presented to the House of Commons in 1812, it is stated that its funds were in a flourishing condition; but it is at the same time added, that the institution seems susceptible of considerable improvement; from which probably it may be inferred, that the objects in the contemplation of the founder have not been fully attained.

The population of Bridgetown, including the parish, exceeds 5000 whites, 1500 free persons of colour, and about 12,000 slaves. The harbour is spacious, and well secured from the prevailing north-east wind. Bridgetown is well defended against the attacks of an enemy; and it is the residence of the governor, and the seat of the public courts and offices of the island.

BRIDGEWATER, a borough-town of Somersetshire in England, is situated in a flat country on the banks of the river Parret, and at the distance of twelve miles from the sea. The communication between the opposite banks is facilitated by means of two bridges, one of stone and the other of iron. The streets are irregular, but they are spacious, and the houses are well built. St Mary's church is a fine structure, with one of the largest spires in the kingdom. A lofty cross is remarkable, by being surmounted with a cistern, from which water is conveyed to the different streets. The river is navigable to the town for vessels of 200 tons burden, and barges ascend as high as Taunton and Langport. The tide rises to the great height of six fathoms at high water and the influx, to the height of ten or twelve feet, is sometimes almost instantaneous. This impetuous flow, of which a similar effect is observed in the mouths of the Ganges, has received the same appellation of *Bore*.

The population, stated in 1801 at 3634, had increased in 1811 to 4911. Bridgewater enjoys a considerable coasting trade, and transmits to the interior parts of Devonshire and Cornwall the manufactures of Birmingham, Manchester, and Liverpool. Coals are imported from Wales, and distributed to the surrounding country; and the fairs, which are held four times in the year, are well supplied with cloths and linen, cattle, horses, and sheep.

BRIDLE, an apparatus variously constructed for regulating the motions of a horse, or keeping him under the restraint of the rider. The bridle originally was of a very simple construction, and consisted only of a cord or thong thrown round the head or neck of the animal. Reins for the management of the horse were in use among the ancients; but it has been doubted whether the curb or bit of modern times was known. The Roman youth were taught the art of guiding their horses while engaged in battle without bridles; and in some sculptures, as those on Trajan's column, soldiers are represented riding at full speed without the appendage of the bridle.

The improved bridle of the present day, composed of the reins, bit or snaffle, and curb, with the occasional addition of chains, is various in the form and dimensions of the different parts. The bit, or snaffle, which is one of the most essential parts of the bridle, and gives the rider great power in the management of the horse, is different in its form and appendages, and has received different names, as the Hessian, the Weymouth, or Pelham bit. The European bridle is usually plain in its construction; but in some countries, and particularly among eastern nations, it is often composed of very expensive materials, and sometimes adorned with a profusion of precious jewels.

It has been truly observed, that the inhabitants of those countries who are much accustomed to the management of horses, make little or no use of the bridle in guiding or directing their motions; and hence it has been justly inferred, that the coercive and harsh treatment of so noble and docile an animal as the horse might be dispensed with, and replaced by gentle treatment and judicious training.

BRIDLINGTON, sometimes called Burlington, is a sea-port town in the east riding of Yorkshire, in England, stands on a bay not far distant from Flamborough-head, and about a mile and a quarter from the harbour called Bridlington-quay. The houses are not of modern date, and the streets are not very regular. The church, of which the nave only remains, seems to have been a fine structure. The number of inhabitants exceeds 3000, and they are chiefly employed in the fisheries and other maritime affairs. Bridlington is a place of considerable resort, on account of its mineral waters and of sea-bathing.

BRIDPORT, a borough town of Dorsetshire; stands in a valley between two branches of the river Brit, about a mile north from Bridport bay. The streets are spacious, and the houses, of brick and stone, are well built. Of the public buildings, the market-house, in the centre of the town, a fine structure, the church of St Mary, a large ancient edifice, the charity-school, and some alms-houses, are the principal. The population, in 1811, was estimated at 3597. The manufacture of small cordage, nets, and sail-cloth, chiefly for the British and Newfoundland fisheries, and the building of ships, particularly smacks for the coasting trade between Scotland and London, furnish employment to the greater part of the inhabitants. An act passed in the time of Henry VIII. ordains that all the cordage used in the English navy should be made at Bridport, or within the limits of five miles. The harbour, lately improved, admits vessels of 200 tons burden.

BRIEF, a term in English law, denoting an abridgement of the case of a client, drawn up for the instruction of counsel in the management of a trial. Brief, in the law of Scotland, signifies a writ issued from the Chancery, and directed to any judge-ordinary, commanding and authorising him to call a jury to inquire into the case alluded to in the brief, and upon their verdict to pronounce a decision.

BRIEF, Apostolical, a letter addressed by the pope to princes and magistrates, relative to any public affair, and distinguished from a bull by being more concise, written on paper, and sealed with red wax. The form of the bull is more ample; it is written on parchment, and sealed with lead, or green wax.

BRIEG, a town of Silesia in Germany, and capital of the principality of the same name, stands on the left bank of the Oder. The houses are generally well built. The principal buildings are the Lutheran college, the academy, the arsenal, and several churches. The town was nearly reduced to ashes in the disastrous siege of 1741, when it fell into the hands of the Prussians, but it has been since repaired and fortified. Spinning and the manufacture of fine cloth have been introduced, and the trade in the wines of Austria and Hungary is considerable. The principality, which is from 12 to 20 miles broad, and about 35 miles long, produces corn, madder, and tobacco.

BRIEL, or BRILL, a sea-port town of Holland, and capital of the island of Voorn, is situated at the mouth of the Meuse, holds the fifth rank among the cities of Holland, and is celebrated in history as the place where the confederates of the United Provinces first established their independence in the struggle between the Dutch and the Spaniards, and laid the foundation of the republic. Being driven from the Low Countries by the Duke of Alva, they retired to England, and having hastily equipped a small fleet, they were compelled by Queen Elizabeth to depart from her territory, in consequence of the complaint of the Duke; and setting sail for the coast of Holland, they were driven, by an unfavourable wind, on the isle Voorn, and having attacked the town of Briel, they became masters of the place, which they afterwards fortified, and made the first asylum of their liberty. In the treaty between the States of Holland and Queen Elizabeth in 1585, Briel was delivered up to the English, in security for the performance of the conditions of the treaty, and was garrisoned by English troops till 1616, when it was restored. This city is also celebrated as the birth-place of the famous Admiral Von Tromp, who fell in a desperate engagement with the English fleet off the Texel, in 1653. Briel is 16 miles from Rotterdam, and 13 miles from Delft.

BRIG, or BRIGANTINE, an appellation denoting a merchant-ship with two masts; but the term is variously applied by different European nations to a vessel of a particular construction of their own marine.

BRIGADE, a term in military affairs, applied to a division or body of soldiers, either horse or foot, composed, when of cavalry, of eight or ten squadrons, and when of infantry, of four, five, or six battalions.

BRIGANTES, a people of Britain, alluded to by the Roman historians, and, according to Camden, occupying the northern counties of England.

BRIGGS, HENRY, an eminent English mathematician of the 16th century, was a native of Yorkshire, and was born in 1556; studied at Cambridge, and, having passed through the degrees of bachelor and master of arts, became at last fellow of his college. His predilection for mathematical science appeared early; and in 1592 he was nominated examiner and lecturer in mathematics, and was afterwards chosen reader of the physic lectures founded by Dr Linacre at Cambridge. Four years afterwards, when Gresham college, in London, was established, Mr Briggs was appointed the first professor of geometry; and while he held this official situation, it appears that his labours extended beyond the mere duties which it required; for he drew up a table for determining the latitude of places from the variation of the magnetic needle, which was published by Dr Gilbert in his treatise *on the Magnet*.

The name of Briggs is, in some degree, associated with the illustrious Napier in the improvement proposed by the former in the system of logarithms, the splendid discovery of which is owing to the latter, who announced it to the world in 1614. On this subject the two learned geometers first corresponded by letter; and in 1616 Mr Briggs visited Scotland, for the purpose of seeing and conversing with Lord Napier, and of discussing the alteration in the logarithmic scale which he proposed. The visit was repeated in the succeeding year; but as it seems

to be hinted, Baron Napier was not much disposed to admit any to a share in the discovery, or to allow Briggs the merit of the improvement to which he was entitled. Briggs asserted his claim in the preface to his *Arithmetica Logarithmica*, which was published in 1624, a work of great labour, which occupied a considerable share of the future part of his life.

In 1619 Mr Briggs was nominated the first Savilian professor of geometry at Oxford; next year he resigned his professorship in Gresham college, and retired to Oxford, where he spent the remaining years of his life, and died in 1630, when he had reached the venerable age of 74. For an account of his works, see Hutton's *Mathematical Dictionary*.

BRIGGS, WILLIAM, an eminent physician of the latter part of the 17th century, was a native of Norwich, studied at Cambridge, and, after travelling on the continent, settled in London. He was the author of a *Theory of Vision*, which was published by Dr Hooke in 1682; and at the suggestion of Sir Isaac Newton, then professor of mathematics at Cambridge, a Latin version of the same treatise appeared in 1685, with a recommendatory epistle by that great man prefixed to it; from which it may be fairly inferred that it is not destitute of merit.

BRIGHTON, or BRIGHTHELMSTONE, a sea-port town of Sussex in England, which, from being only a village chiefly inhabited by fishermen, has become a place of considerable extent, and of great resort for sea-bathing. It is chiefly built on a rising ground, with a gentle slope towards the east, and is well sheltered from the north and north-east winds by the South Downs. The new streets are regularly laid out, and are furnished with many elegant houses; but the chief ornaments of Brighton are the Steyne and Crescent, which consist of splendid lodging-houses, the Marine Pavilion, the magnificent residence of the Prince of Wales, the fine mansion of the Duke of Marlborough, a theatre, two elegant assembly-rooms, public libraries, a church and a chapel belonging to the establishment, and churches and meeting-houses for other denominations. The baths near the Steyne were erected in 1789, and are commodiously fitted up with hot, cold, vapour, salt-water, and air-pump water baths; and not far from the town a mineral spring, of a chalybeate nature, has been found useful to invalids who frequent the place.

The population of Brighton, estimated in 1801 at 7339, in 1811 exceeded 12,000; but this number, it is supposed, includes more than the permanent inhabitants, to whom the mackarel and herring fisheries afford the principal and often a very lucrative employment. Brighton also derives some advantage from its maritime situation, as being the station of the packet-boats between this part of the English coast and Dieppe in France; but the chief support of this place is derived from its baths, which for some years past have become a fashionable resort for the most distinguished company in the kingdom. Brighton is 55 miles from London.

BRIMSTONE, or SULPHUR, an inflammable substance; for the properties and combinations of which see CHEMISTRY.

BRINDISI, the Brundusium of the ancient Romans, and the scene of many important events connected with the history of that people, is a city of Italy in the Terra d'Otranto, and kingdom of Naples. The irruption of the Vandals was fatal to Brundusium, and it was nearly destroyed by the Saracens about the beginning of the ninth century. During the crusades it was the chief rendezvous of the armies collected in Europe destined for the conquest of the Holy Land, and recovered some degree of its former prosperity.

Of the ancient city, part of the light-house, a capacious marble bason, supplied with water from deers heads of brass, fragments of columns, pieces of coarse mosaic, inscriptions, coins, and ruins of aquæducts, are the only remains. The walls of the modern city include a spacious area, which is scarcely half occupied with inhabited houses. The streets are irregular and ill paved, and the houses are decayed and ruinous. The harbour of Brindisi is one of the safest and most commodious in the Adriatic, and from its local situation affords great facilities for commercial enterprize; but at different times it has been greatly injured by sinking ships and throwing in heaps of rubbish into the passage, to prevent the approach of hostile invaders.

The population of Brindisi is stated by some at 2000, and by others at 6000; but perhaps this difference may arise from the sad reverses to which this place has been subject by pestilential disorders, during some of which 1500 persons have been swept away in the course of a few weeks. This excessive mortality is ascribed to the noxious exhalations from the marshes in the neighbourhood. The soil in the vicinity produces vines, olives, and cotton; the latter of which furnishes employment to some of the inhabitants.

BRINDLEY, James, a celebrated English engineer, remarkable for the extraordinary powers of native genius, unaided by education; he was born at Tunsted, in Derbyshire, in 1716; and to the imprudence of his father in the management of a small patrimonial property, and his consequent embarrassment, the defects of the son's education are ascribed. Having finished his apprenticeship to a millwright near Macclesfield, in Cheshire, he commenced business for himself, and by his improvements in machinery, or by his own inventions, soon acquired the reputation of an ingenious mechanic. But the powers of his genius were not confined to the immediate business of his profession. The construction of a water-engine at Clifton, in Lancashire, for draining coal-mines, the improvement of a silk-mill in Cheshire, and some valuable additions which he made to the flint-mills in Staffordshire, fully established his reputation as an able engineer.

But the fame of Brindley is closely associated with the splendid works which were begun and carried on under his superintendence by the liberal and patriotic Duke of Bridgewater, who first introduced on a large scale the plan of inland navigation, which has proved of such incalculable benefit to the manufactures and trade of the kingdom; and in the construction of canals no difficulties were too great for the inexhaustible sources of his ingenuity. He carried them over wide vallies and large rivers by means of aquæducts, and through mountains by means of subterraneous tunnels. The first canal in which he was engaged was between the Duke's coal-works at Worsley and Manchester, for the purpose of supplying that town with fuel at a cheap rate; the plan was extended, and a similar communication was formed with Liverpool. The apparent advantages of water-carriage was so great that the proprietors and manufacturers of Staffordshire were induced to engage Mr Brindley to make a survey from the Trent to the Mersey, and, according to his plan, the canal was begun in 1766, and continued under his direction as long as he lived, and was finally completed under the management of his brother-in-law, Mr Marshall, in 1777. To this splendid undertaking he gave the name of the Grand Trunk Navigation, on account of the numerous branches which he supposed would in time be extended from it. This canal is 93 miles in length; and beside a great number of bridges thrown over it, has 76 locks, and five subterraneous tunnels, one of which, at Harecastle, is 2880 yards in length, and more than 70 yards below the surface of the earth.

Mr Brindley was engaged in many other works, chiefly of a similar nature. He was carried off in the year 1772, when he had reached his 56th year. Intense application, it is supposed, shortened his days, and induced a hectic fever, which rarely left him during the latter years of his life. For the common amusements of the world he had no relish, and therefore never indulged in them, or relaxed his mental exertions in devising the means for the accomplishment of the great plans which he had contrived or suggested. It was his practice, when any unusual difficulty arose in carrying on his works, to retire to bed, and sometimes to remain two or three days till he had surmounted the difficulty; and, without model or drawing, put the design which he had formed in execution. The fame of Brindley is finely commemorated in the poetry of Darwin:

> So with strong arm immortal Brindley leads
> His long canals, and parts the velvet meads;
> Winding, in lucid lines, the watery mass,
> Mines the firm rock, or loads the deep morass;
> With rising locks a thousand hills alarms,
> Flings o'er a thousand streams its silver arms,
> Feeds the long vale, the nodding woodland laves,
> And plenty, arts, and commerce freight the waves.
>
> *Botanic Garden, Canto 3.*

BRISAC, a town of Germany, and capital of Brisgaw, stands on the right bank of the Rhine, and was at one time a place of great strength, and the scene of many severe struggles for its possession between France and Austria. It was restored to the empire in 1715, and in the year 1741 the fortifications were entirely destroyed. Brisac is 40 miles from Strasburgh, and 27 miles north from Basle.

BRISAC, New, a town in the district of Colmar, stands nearly opposite to the former, and about a mile distant from the left bank of the Rhine. It was built by Louis XIV. and fortified by the celebrated Vauban. The population is stated at 2000.

BRISGAW, a district in the circle of Swabia in

Germany, extends along the east bank of the Rhine about 50 miles, and is about 30 miles in breadth, including within its territory Freyburg the capital, Brisac, Rhinmarck, and an island in the Rhine.

BRISTOL, from *Brightston*, the Saxon name, a city and sea-port, which stands on an elevated situation between the rivers Avon and Frome, partly in Somerset, and partly in Gloucestershire, in England; and, for opulence and commercial activity, is inferior to few towns in the kingdom, with the exception of the metropolis. Bristol lays claim to considerable antiquity. According to tradition, it was built nearly four centuries before the Christian era; but before the middle of the 5th century it is recorded as one of the fortified cities of Britain. It was surrounded with a wall, and defended by a castle, built about the middle of the 12th century; and, being regarded as a place of great strength, continued to be an object of importance to contending parties till the time of Oliver Cromwell, when the fortifications were razed to the ground by his order in 1665.

Bristol is about seven miles in circumference, and in one direction is about three miles long; about two-thirds of the space which it occupies belong to Gloucestershire; and the number of streets, lanes, courts, and squares, is computed at 600. The streets of the old town are crowded and less regularly disposed, and the houses are chiefly built of wood and plaster; but in the suburbs, and modern parts of the city, the houses, which are of brick or stone, are elegant, and the streets spacious and commodious. The chief buildings of Bristol are the cathedral, the church of St Mary Radcliffe, a fine Gothic structure, the exchange, the coffee-room, the theatre, the assembly-rooms, the guildhall, the mansion-house, and the custom-house, beside the infirmary, several hospitals, and other benevolent institutions. Bristol was erected by Edward III. in 1372, into an independent county, and since that period has received various privileges and immunities. The municipal government is entrusted to a mayor, twelve aldermen, justices of the peace, sheriffs, common-councilmen, &c. The bishopric was founded by Henry VIII.

The population of Bristol, which in 1801 amounted to 63,645, had advanced in 1811 to 71,297. The woollen manufactures, which were once flourishing and extensive, are now limited to serges and some other woollen stuffs; but the manufacture of glass is conducted on a large scale, as well as the refining of sugar and soap-making. Distilleries, iron-founderies, at which cannon are cast and bored, manufactures of brass, zinc, and lead shot, of white and red lead, turpentine, sulphur, and sulphuric acid, and of china-ware, have been established and successful. The manufactory of pins and other brass wares at Warmley, between Bristol and Bath, gives employment to many hundred persons; and the machinery is set in motion by two steam-engines.

Bristol has been long celebrated for commercial enterprize; the merchants of this city are extensively concerned in the West India trade, as well as with different parts of Europe. Its situation is peculiarly favourable; and the improvements which have been made of late years, in the navigation of the river and the formation of ample wet-docks, afford the greatest facilities to its commercial activity.

Bristol is a place of great resort during the summer months on account of its mineral waters. The spring rises at the bottom of St Vincent's rocks, close by the river, and about a mile west from the city; it is so copious that it discharges nearly forty gallons in a minute. The temperature is $74\frac{1}{2}$ Fahrenheit; and the saline ingredients with which the water is impregnated are muriate of magnesia, common salt, sulphate of soda, sulphate of lime, and carbonate of lime, beside carbonic acid gas. These waters are found highly beneficial in various diseases; and it can scarcely be doubted that the pure air and romantic scenery in the vicinity contribute their share to the restoration of the health of the invalid.

BRITAIN.

Introduction

No part of the inhabited globe, whether we consider its natural advantages, its national character, or its political importance, is more worthy of our notice than the island of Great Britain; and in sketching the principal features which it exhibits, we shall attend, first, to its statistics, and then to its civil history.

PART I. STATISTICS.

Chap. I. Name, Boundaries, Extent, and Division.

Name.—Etymologists are not agreed as to the origin of the name Britain, some tracing it to *Brutus*, or *Brito*, grandson of the Trojan prince Æneas, some to *Pryd Cain*, signifying a white form; some to *Brith*, painted; some to *Brydio*, rage; and others to *Barat Anas*, the country of tin. Without, therefore, presuming to decide between these different and discordant conjectures, let it suffice to observe that, in the time of Julius Cæsar, this designation was substituted for that of Albion, by which the island had been previously known.

Statistics.

Boundaries and extent.—Britain is bounded on the south by the English channel, on the north by the Deucaledonian sea and Pentland firth, on the east by the British or North sea, and on the west by the Atlantic ocean and St George's and the Irish channels. It extends from 50° to $58^{\circ}\ 42'$ north latitude, and from $1^{\circ}\ 46'$ east to $6^{\circ}\ 30'$ west longitude from Greenwich, being about 600 miles in a straight line, from the Lizard-point to Duncansbay-head, and 310 from the South Foreland to the Land's-end; containing a furface of about 85,500 square miles, or 54,720,000 acres.

Division.—The river Tweed, the Cheviot hills, and the Solway firth, divide the island into two parts, called SOUTH and NORTH BRITAIN, or England and Scotland.

SOUTH BRITAIN, before the Roman invasion under Julius Cæsar, was parcelled out into *seventeen* petty states, each governed by a separate king. The 1st, including Cornwall and Devonshire, was inhabited by the *Domnonii;* the 2d, Dorsetshire, by the *Durotriges;* the 3d, Wiltshire, Somersetshire, and the principal part of Hampshire, by the *Belgæ;* the 4th, Berkshire, by the *Atrebattii;* the 5th, Surry, Sussex, and the sea-coast of Hampshire, by the *Regni;* the 6th, Kent, by the *Cantii;* the 7th, Gloucester and Oxfordshires, by the *Dobuni;* the 8th, Buckinghamshire, Hertfordshire, and Bedfordshire, by the *Catecuchlani;* the 9th, Essex and Middlesex, by the *Trinobantes;* the 10th, Suffolk, Norfolk, Cambridgeshire, and Huntingdonshire, by the *Iceni;* the 11th, the counties of Northampton, Leicester, Rutland, Lincoln, Nottingham, and Derby, by the *Coritani;* the 12th, Cheshire, Shropshire, Staffordshire, Worcestershire, and Warwickshire, by the *Cornavii;* the 13th, Radnorshire, Brecknockshire, Glamorganshire, Herefordshire, and Monmouthshire, by the *Silures;* the 14th, Caermarthenshire, Pembrokeshire, and Cardiganshire, by the *Demetæ;* the 15th, Flintshire, Denbighshire, Isle of Anglesea, Caernarvonshire, Merionethshire, and Montgomeryshire, by the *Ordovices;* the 16th, Yorkshire, Lancashire, Durham, Westmoreland, and Cumberland, by the *Brigantes;* and the 17th, Northumberland, by the *Ottadeni.*

Roman Provinces.—But after the Romans gained possession of South Britain, they divided it into four great provinces. These were, BRITANNIA PRIMA, comprehending that extensive tract from the English channel to the mouths of the Severn and the Thames; BRITANNIA SECUNDA, constituting the territory of modern Wales; FLAVA CÆSARIENSIS, extending from the Thames to the Humber; and MAXIMA CÆSARIENSIS, stretching from the Humber on the east, and the Dee on the west, to the wall of Adrian between the Tyne and the Solway firth. The remaining part was included in the province of VALENTIA.

Heptarchy.—Under the Saxons, who, about the middle of the fifth century, had effected a settlement in the island, England was divided into *seven* kingdoms, generally styled the HEPTARCHY. The names, commencement, and extent of these kingdoms were as follows. *Kent,* founded by Hengist in 455, embraced the county now distinguished by that appellation. *Sussex,* erected by Ella in 477, contained Sussex and Surry. *Wessex,* established by Cerdic in 519, included Cornwall, Devonshire, Dorsetshire, Somersetshire, Wiltshire, Hampshire, and Berkshire. *Essex,* erected by Erchewin in 527, comprehended Essex, Middlesex, and part of Hertfordshire. *Northumberland,* founded by Ida in 547, comprised Lancashire, Yorkshire, Durham, Cumberland, Westmoreland, Northumberland, and Scotland northward to the firth of Forth. *East Anglia,* established by Uffa in 571, embraced Norfolk, Suffolk, Cambridge, and the isle of Ely. And *Mercia,* erected by Creda in 584, included Gloucestershire, Herefordshire, Worcestershire, Warwickshire, Leicestershire, Rutlandshire, Northamptonshire, Oxfordshire, Staffordshire, Shropshire, Derbyshire, Nottinghamshire, Cheshire, and the remainder of Hertfordshire.

Counties.—After many violent struggles for the ascendancy, these kingdoms were, in 828, united under the dominion of Egbert, king of Wessex, when they were, for the first time, denominated *England,* a name of uncertain etymology. By his grandson, Alfred the Great, England was divided into 32 counties; each of which was originally governed by a *count,* who, on his dignity and title becoming hereditary, appointed a deputy, called the *shire-reeve, shrieve,* or *sheriff;* that is, the manager of the *shire, share,* or division. But this number has been since augmented to 40, and, including Wales, to 52 counties. These are the following: Four *southern* counties, Dorsetshire, Hampshire, Wiltshire, and Berkshire: Three *south-western,* Cornwall, Devonshire, and Somersetshire: Three *south-eastern,* Sussex, Kent, and Surry: Four *bordering on Wales,* Monmouthshire, Herefordshire, Shropshire, and Cheshire: Twelve *midland,* Bedfordshire, Buckinghamshire, Oxfordshire, Gloucestershire, Worcestershire, Warwickshire, Northamptonshire, Rutlandshire, Leicestershire, Staffordshire, Derbyshire, and Nottinghamshire: Eight *eastern,* Middlesex, Hertfordshire, Essex, Suffolk, Norfolk, Cambridgeshire, Huntingdonshire, and Lincolnshire: Six *northern,* Lancashire, Westmoreland, Yorkshire, Durham, Cumberland, and Northumberland: Six of *South Wales,* Glamorganshire, Brecknockshire, Caermarthenshire, Pembrokeshire, Cardiganshire, and Radnorshire: And six of *North Wales,* Montgomeryshire, Merionethshire, Caernarvonshire, Anglesea, Denbighshire, and Flintshire.

Three of these counties, namely, Durham, Cheshire, and Lancashire, are termed *counties palatine,* having been invested by the crown with regal rights and prerogatives. And, distinct from the counties in which they are situated, some cities and boroughs are styled *counties corporate;* the kings of England having annexed to them certain territories, and granted them the liberties and jurisdiction of counties. Of this description are the cities of York, Chester, Bristol, Norwich, Exeter, and Worcester, and the towns of Poole, Haverford-west, Southampton, Newcastle-upon-Tyne, Berwick-upon-Tweed, and Kingston-upon-Hull.

Counties, again, have been sub-divided into trithings, lathes, rapes, hundreds, tithings, wards, and wapentakes. By *trithings* is meant a threefold partition, such as that which still obtains in Yorkshire, where the appellation is now corrupted into *ridings.* Almost synonymous with trithings are *lathes* and *rapes;* the former of which designations is met with only in Kent, and the latter in Sussex. Every *hundred* includes a hundred families, and every *tithing* ten. The terms *wapentakes* in Yorkshire, and *wards* in Cumberland, Westmoreland, Northumberland, and Durham, are applied to small districts, whose inhabitants were, in ancient times, obliged to *take up weapons,* and to *watch* against the irruptions of their northern enemies, the Picts and Scots.

NORTH BRITAIN, at the time of the Roman invasion, was also divided into a number of petty states, inhabited by independent tribes of Aboriginal

Statistics.

Britons: these were 21 in number. Together with Northumberland, the *Ottadeni* occupied the counties of Berwick, Roxburgh, and Haddington. The *Gadeni* extended over Selkirkshire, Peebleshire, most of Edinburghshire, and nearly all Linlithgowshire. Dumfries-shire, and Kirkcudbrightshire, westward to the river Dee, were inhabited by the *Selgovæ;* and the rest of Kirkcudbrightshire, and the whole of Wigtonshire, by the *Novantes*. The *Damnii* possessed Ayrshire, Renfrewshire, Lanarkshire, Stirlingshire, and the remainder of Edinburghshire and Linlithgowshire, with a portion of the shires of Dumbarton and Perth. The *Horestii* spread over the counties of Clackmanan, Kinross, Fife, and part of Perthshire on the south. The eastern side of Perthshire, the whole of Angus-shire and Mearnshire, northward to the river Carron, were occupied by the *Venricones*; while the rest of Mearnshire, and nearly the whole of Aberdeenshire, were inhabited by the *Taxaili*. The *Vacomagi* held Braemar in Aberdeenshire, the whole of the shires of Banff, Murray, Nairn, and the eastern part of Inverness-shire. The *Albani*, afterwards called *Damnii Albani*, inhabited Athol and Braidalbin in Perthshire, Glenorchy and Appin in Argyllshire, with a small portion of Lochaber in Inverness-shire. The *Attacotti* possessed Cowal in Argyllshire, and the most of Dumbartonshire; the *Caledonii*, the interior of the counties of Inverness and Ross; the *Cantæ*, the eastern parts of Ross-shire, from the Moray firth to the Dornoch firth; and the *Logi*, the south-east coast of Sutherland, from the Dornoch firth to the river Ila. Caithness-shire on the south, the east, and the north-west, was occupied by the *Carnabii*; its north-west corner, and part of the county of Sutherland, by the *Catini*; the interior of Sutherland by the *Mertæ*; its northern and western coasts, and a small part of the western shore of Ross-shire by the *Carnonacæ*; and the remainder of the western shore of Ross-shire by the *Creones*. The *Cerones* possessed the west coast of Inverness-shire, and a considerable portion of Argyllshire; and the *Epidii*, the south-west of Argyllshire, from Linne-loch to the Mull of Cantire.

Provinces.—During the Roman period, North Britain was divided into three provinces, Valentia, Vespasiana, and Caledonia. The first extended from the wall of Adrian to Graham's dyke, between the Clyde and the Forth: the second stretched over that tract of country which was bounded on the south by Graham's dyke and the Forth, on the north and east by the German ocean, and on the west by a straight line running from Loch Linnhe to the Moray firth; Caledonia comprehended the remainder, namely, the north-west corner of Argyllshire, and the whole of the counties of Inverness, Ross, Sutherland, and Caithness. But sometimes this last, in the middle ages styled Albania, embraced all the territory beyond the Forth and Graham's dyke; and at other times, in its most enlarged sense, all that part of the island northward of the Tweed, the river Eden, and the Solway firth.

Kingdoms.—On the departure of the Romans from Britain, Scotland was soon occupied by four warlike and independent powers. To the kingdom of Northumberland, formerly mentioned, belonged *Bernicia*, or Lothian, including the shires of Berwick, Roxburgh, Haddington, Selkirk, Peebles, Edinburgh, and Linlithgow. The *Cambrian* kingdom, or as it is most generally designated, the kingdom of Strathclyde, founded about the middle of the fifth century, reached westward from the counties now enumerated, to the Irish sea, and from the river Eden and the Solway firth to the Clyde, Loch Lomond, and the Forth. Subsequently to the Roman abdication in 446, the kingdom of *Pictavia*, inhabited by the Picts, descendants of the ancient Caledonians, spread over the whole region on the north of that boundary; and its extent continued undiminished, until a colony of Scots, sometimes called Dalriads, from Ireland, effected a settlement in Argyllshire and some of the circumjacent districts, where they established a kingdom in 503. After a struggle of 340 years between the Picts and the Scots, the latter prevailing, both were united into one sovereignty under Kenneth the son of Alpin. Strathclyde and Lothian, too, at length merged in the Scottish nation, and from that time the common country was denominated Scotland.

Counties.—The division of North Britain into shires or counties, unknown till the Scoto-Saxon period, which extended from the year 1097 to the year 1306, seems to have been gradually introduced as the Saxon colonists gained upon the Gaelic inhabitants. These counties, as they at present stand, are *thirty-two*, and taking in Orkney and Shetland, *thirty-three* in number. They may be arranged in the following order: Six *northern* counties, Orkney, Caithness, Sutherland, Ross, Cromarty, and Inverness: Fourteen *midland* counties, Argyll, Bute, Nairn, Moray, or Elgin, Banff, Aberdeen, Mearns, or Kincardine, Angus, or Forfar, Perth, Fife, Kinross, Clackmanan, Stirling, and Dumbarton, or Lennox: Thirteen *southern* counties, West-Lothian, or Linlithgow, Mid-Lothian, or Edinburgh, East-Lothian, or Haddington, Berwick, Renfrew, Ayr, Wigton, Lanark, Peebles, Selkirk, Roxburgh, Dumfries, and Kirkcudbright.

Chap. II. Aspect of the Island.

The island of Great Britain forms an irregular figure, not unfitly represented on the coins of Antoninus Pius and Severus, by a woman sitting upon rocks. Its shores, which are much deflected by deep inlets and projecting headlands, are in some places marshy, flat, and tame, and in others, bold, precipitous, and wild. In its general surface, the great diversity of its features presents to the eye a highly picturesque and delightful prospect. Here are extensive plains, laden with all the riches of luxuriant vegetation; and there gently rising hills, covered with waving woods, flocks of cattle, and fields of corn. Here are craggy and dusky mountains, burying their alpine heads in the clouds; and there, narrow winding ravines, with the foaming torrent tumbling, with terrific grandeur, down its steep and rugged channel. Here are beautiful lakes, whose pure and unrippled waters give back the sublime and enchanting landscapes on their banks; and there, majestic rivers sweeping their serpentine course through a long tract of country, and appearing at a distance like stripes of crystal amidst the surrounding verdure. The scene is not a little

Statistics.

varied, enlivened, and adorned, by smiling meadows, bustling cities, towns, villages, princely seats, and pleasure grounds. But it will be necessary to attend more particularly to some of the more striking features.

Sea-coasts.—In proceeding eastward along the *southern* shore, from the Lands-end, a high rugged projection, the spacious bay of St Michael, soon opens on the view; and on doubling the Lizard point there appears a large semicircular sweep, including, among other inlets and capes, Falmouth haven, Rame-head, and Plymouth sound. Nearly opposite to Rame-head, about fourteen miles in the sea, are situated the Eddystone rocks, over which the waves frequently break with tremendous violence, and on which is built a strong light-house, for the direction of vessels entering and leaving the Channel and Plymouth sound. Between Prawle-point and Portland-bill, is another vast indentation, the most remarkable objects in the curvature of which are, Start-point, the bay of Dartmouth, Froward-point, Torbay, Hopes-nose, and the estuary of the Ex. Next follow Portland road, Weymouth bay, and St Alban's head. From this promontory to Selsey-bill, the coast is very much deflected by several creeks and headlands; among which are Peverel-point, Sandwich bay, Poole harbour, with an island in its entrance, Christchurch bay, Hurst cape, Southampton water, Portsmouth harbour, and a capacious basin interspersed with small islands. Opposite to the estuary of Southampton lies the isle of Wight, which forms, with the main land, a sheltered channel, consisting of the Needles passage, the Solent, and the famous road of Spithead. Beyond Selsey-bill, the shore in general takes a north easterly direction, and nothing remarkable occurs until Beachy-head, a bold and elevated point, makes its appearance. The only other objects which attract particular attention are the Rock of Hastings, Dunge-ness, and Dover-cliffs.

Off Kent, as we enter on the *eastern* coast, are the Downs, a road much frequented by ships, and defended from the heavy swells of the British ocean by the Goodwin sands, which are situated about five miles distant from Deal. Here a level sandy beach separates the high chalky rocks which face the coast, for a considerable way on each side of the South Foreland, from those which skirt the bold and rugged shore of the isle of Thanet, a place formerly detached from the rest of Kent by a navigable river, but now little more than a peninsula. The most easterly point of this isle is the North Foreland; between which and Orfordness, there is a vast gulph, into which the rivers Medway, Thames, Crouch, and Maden, discharge their waters, and along which, the shore, after passing the Shippey isle, is for the most part flat and marshy. From Orfordness to the spacious inlet called the Wash, the coast assumes a circular direction, and presents an intermixture of low ground, sandy hillocks, and clayey precipices. Crossing the Wash, and keeping the level beach of Lincolnshire, we come to the Humber, beyond which, to the firth of Forth, there are few indentations and promontories of any note. From Spurn-head to Flamborough-head, the coast is commonly flat; from this to Bamborough castle, it is first bold and precipitous, and then descends to low cliffs of sandstone and other materials; and from this again to Berwick-upon-Tweed, it is tame and sandy, but afterwards becomes bold and rocky, especially at St Abb's head, and westwards. Not far from the shore, opposite to the Northumbrian coast, appear the Coquet isle, the Fern isles, and Holy isle.

Statistics.

Between Fife-ness and Button-ness, on the other side of the Forth, there is a considerable inlet, containing the estuaries of the Eden and the Tay. The land here rises gradually from the shore, which, for the most part, is rather high and rugged. Beyond this the coast runs N. N. E. with but few windings to Kinnaird's-head, and is generally bold, and sometimes lofty and precipitous. The Redhead promontory, in Angus-shire, rears its perpendicular front about 200 feet above the sea; and in the county of Mearns there is a stupendous eminence, called Fowls-heugh, about a quarter of a mile long, and nearly 300 feet high, whose base is beaten with fury by the swelling billows. But the bullers or boilers of Buchan, in Aberdeenshire, present an object of the most majestic and terrific grandeur. These consist of a spacious cavity, open at the top, formed by projecting rocks of immense elevation, and perforated towards the ocean by an arched way, through which the water rushes into the basin, where it foams and boils up like the ebullitions of a cauldron. A vast triangular indentation, including the Moray, Cromarty, and Dornoch firths, occupies the whole space from Kinnaird's-head to Duncansbay-head; and on both the land sides of the triangle, the shore is, with some exceptions, elevated, steep, and magnificent. On the eastern coast, particularly of Scotland, there are many excavations, or caverns, running far into the rocks, and which sometimes afford excellent specimens of stalactitic petrifactions.

The *northern* coast, which extends nearly 70 miles in a south-westerly direction, exhibits a bold and precipitous appearance. In some places the rocks, with which it is lined, rise to a stupendous height, frowning in sullen majesty over the sea below. Duncansbay-head and Dunnet cape, about 12 miles distant from each other, are two projections of very conspicuous elevation; the latter of which is not less than 400 feet above the surface of the water. To the northward of these projections, separated from them by the Pentland firth, are situated the Orkney islands; and a great way off, to the north-east, those of Shetland. Passing many bays, openings, and headlands, we arrive at cape Wrath, a dreadful precipice, which completely justifies the application of its name by the violence with which it repels the raging waves which dash against its proud and lofty front.

From cape Wrath to the Mull of Galloway on the *western* coast, the promontories and recesses are too numerous to be here particularly described. The most considerable are, Ardnamurchan's point, the most westerly projection of the island, Loch Linnhe, the Mull of Cantire, and that spacious bay into which Loch Fine and the estuary of the Clyde open. Along this stretch of coast, the shore, from which the ground often rises suddenly into mountains of alpine grandeur, is commonly bold, rocky, and dangerous. Opposite are the Hebrides or *Western isles*, the principal of which are Lewis, North and South Uist, Skye, Mull, Islay, and Jura; and, not properly included in this designation, are two beautiful islands, Bute and Arran, lying at the mouth of the Clyde. Between the Mull of Galloway and Braich-y-pwll point, where the shore is partly flat and partly bold and elevated, there is a wide inlet, containing, among other intrenchments, the bays of Glenluce and Wigton, the estuary of the Solway frith, Morecombe bay, and the estuaries of the Ribble, the Mersey, and the Dee. In almost the centre of this inlet is the isle of Man, and directly south from it the isle of Anglesey, separated from the main land by a long and narrow passage, called the Menai straits. Cardigan bay, another immense opening, stretches from Braich-y-pwll point to St David's head, presenting a coast in general rugged, mountainous, and wild; and between St David's head and the Land's-end there is another vast indentation, which gives space to St Bride's bay, Milford haven, Caermarthen and Swansea bays, Bristol channel, or estuary of the Severn, and Barnstaple bay. The beach along this tract continues mostly high and rocky; off from which there are some small scattered islands, of no particular note, if we except the isles of Scilly, which lie nearly 30 miles west from Cornwall.

Thus, it may be observed, the horizontal position of the island resembles somewhat the shape of a wedge, shelving from west to east, and may be considered as not unfitly represented in miniature by the Salisbury crags near Edinburgh.

Mountains and hills.—The mountains and hills form the most prominent feature in the face of a country; a feature for which Great Britain is eminently distinguished. On the south of the island a group called the Devonian range, stretches from the Land's-end through Cornwall, Devonshire, and part of Somersetshire, and rises at its greatest height to 1800 feet above the level of the sea; from which level the following admeasurements are also calculated. A ridge, likewise of considerable elevation, runs from the sea coast of Dorsetshire north-east to the county of Suffolk, with two lateral branches extending from the plain of Salisbury, the one to Sussex, where it forms the South Downs, and the other to the eastern shore of Kent. The Cambrian range, which traverses Wales from south to north, boasts of Plinlimmon in Montgomery and Cardigan shires, whose altitude is 2463 feet; the steepy Cader Idris in Merionethshire, 2914; and the cliffy Snowdon in Caernarvonshire, 3571. Another range, sometimes styled the Apennines of England, commences in Derbyshire, and terminates at Geltsdale forest in Cumberland, having a ramification shooting off on the north of Westmoreland towards the Irish sea. Of this range, in Westmoreland, Wharnside 2475 feet, Bonyfell 3084, and Ingleborough 2380,—in Yorkshire, Crossfell 3390, Bowfell 3440, and Helvellin 3225,—and in Cumberland, Grasmire 2865, Saddleback 3048, Skiddaw 3175, and Seafell 3240,—are the principal mountains. In different parts there are other hills and mountainous tracts of inferior note; such as the Chiltern hills, between Tring in Hertfordshire and Henley in Oxfordshire; the Malvern hills in Gloucester, Hereford, and Worcester shires; the Cotswold and Stroudwater hills in Gloucestershire; the Wrekin in Shropshire; the Morelands of Staffordshire, Yorkshire, Lancashire, and Northumberland.

The Cheviot, Tiviot, or Border hills, celebrated in the ballad of "Chevy Chase," for a battle between the Scots and the English under Douglas and Percy, run in a westerly direction, and form a continuous chain with those in the south-west region of Scotland. Many of the elevations in this chain are very considerable. In Roxburghshire, Cheviot Top is 2682, and Millenwood Fell 2000 feet; in Selkirkshire, Etterick Pen 2200, Windleshaw Law 2295, and Blackhouse Heights 2370 feet; in Dumfriesshire, Lauders 3150, Hartfell 3300, and Black Larg 2890 feet; in Kirkcudbrightshire, Criffel 2044, and Cairnsmuir nearly 4000 feet; and in Lanarkshire, Leadhills 1564, and Tinto 2368 feet. The rugged and heathy mountains of Tweedsmuir, in Peeblesshire, rise in Hartfield and Broadlaw to about 2800 feet; Loganhouse-hill, 1700 feet, is the highest of the Pentland ridge in Edinburghshire; and between East Lothian and Berwickshire, the Lammermuir chain, which terminates in St Abb's head on the eastern coast, has Soutra-hill, 1000 feet, for its greatest altitude. In Fifeshire, there is a small ridge, with two conical eminences, called the Eastern and Western Lomonds, the former of which is 1260, and the latter 1280 feet. An extensive chain, commencing at Dumbarton, and stretching in a north-easterly direction to the neighbourhood of Brechin, is by the Forth and the Tay broken into three divisions, denominated the Lennox, the Ochil, and the Sidlaw-hills. To the first division belong the Campsy Fells in Stirlingshire, 1500 feet; to the middle division, Dumiat, in the same county, upwards of 2000 feet, and Bencleugh, in Clackmannanshire, 2420; and to the last division, Dunsinnan-hill, 1025 feet, King's-seat 1400, and Kinpurnie, 1151, in Perthshire, and Craigowl, in Angus-shire, 1600. The Grampian range, so designated from the *Mons Grampius* of Tacitus, where the Caledonians were defeated by the Romans under Agricola, extends from Loch-Lomond, in Dumbartonshire, to Stonehaven, in the county of Mearns, having a branch shooting off from it into the shires of Inverness and Banff. Of this range Stirlingshire claims Ben-Lomond 3260 feet, Perthshire Ben-Ledi 3009, Ben-More 3903, Ben-Lawers 4015, Ben-Voirlich 3300, Bengloe 3725, and Shechallien 3564; Aberdeenshire, Loch-na-garaidh, and Binn-na-muich-duidh, which are constantly covered with snow, and not less than 4000 feet; Kincardineshire, Kloachnabane 2370, and Mountbattock 3465 feet; Inverness-shire, Cairngorm 4060 feet; and Banffshire, Benrinnes 2650 feet. It would be difficult to group the remaining mountains; because, from their irregular and insulated positions, few of them can be reduced to any distinct arrangement. Let it suffice, therefore, to mention some of the most remarkable, following the order of the counties in which they are placed. Ben-Cruachan, in Argyleshire, is 3390 feet; Ben-Nevis, in Inverness-shire, the loftiest mountain in Great Britain, raises its rugged front 4370 feet; Ben-Wyves, in Ross-shire, is 3720, and Benuaish nearly the same height; Ben-Hope, in Sutherlandshire, and the Pap of Caithness, are each of considerable elevation; the latter is 1920 feet.

Lakes.—Although many of the British lakes are well calculated to reward the visit of the traveller, yet comparatively few, in the southern division of the island, possess striking peculiarity of character, or exhibit features of wild and impressive grandeur. It is not among the fens of Huntingdonshire, Cheshire, and Lincolnshire, that these are to be found; but among the mountains of Wales, and particularly those of the north-west of England. Lyn Savadham in Brecknockshire, Bosherton-mere in Pembrokeshire, and Lyn Tegid in Merionethshire, are each worthy of notice; the first for the long thundering sounds which it emits on the bursting of the ice in the return of spring; the second for the rumbling noise heard from many parts of it before a change of weather; and the other for keeping within its banks, even on the reception of the most copious torrents, and for overflowing them when agitated by storms of wind. In Lancashire, Coniston-mere, six miles long, and three-quarters of a mile broad, has its shores finely indented by a succession of small bays; and, in connexion with the surrounding scenery, presents to the eye a soft and delicate landscape. Winder-mere, between the counties of Lancaster and Westmoreland, is in length 15 miles, and in average breadth one mile. The hills which hem in its borders generally ascend in a gentle acclivity, but in some places rise in abrupt and perpendicular rocks; and the romantic beauty of the picture is not a little heightened by the wooded islands which stud its waters. Ulls-water, between Westmoreland and Cumberland, is nine miles long, and upwards of one at its greatest breadth, and is unequalled in England for the vastness and sublimity of its accompaniments. Buttermere, in Cumberland, about a mile and three-quarters long, and half a mile broad, is formed by cataracts falling from a rock of stupendous height, and is guarded on the west by a ridge of rugged mountains which tower precipitately from its edge. To the north of this, Crummock-water expands itself into four miles in length, and nearly half a mile in breadth; and, for the interest which it excites, is indebted to the isles which rise from its surface, and to the rich and varied drapery of the mountains which skirt its sides. Derwent-water, three miles long and one and a half broad, and Bassenthwaite-water, four miles long, and a mile across at its greatest breadth, are highly distinguished for their picturesque and imposing beauties. The former of these two lakes, besides being decorated with islands, strikes the visitor with its brilliant transparency, and sometimes with its violent agitations without any apparent cause.

The lakes in Scotland, not to mention those *arms* of the sea by its inhabitants improperly called *lochs*, are more numerous, and in general formed on a grander and more extensive scale. Loch-Leven, in Kinross-shire, is a beautiful sheet of water, about 12 miles in circumference, interspersed with four islets, and is of great historical notoriety, both for the siege of its castle by Sir John de Stirling in 1335, and for being the spot where the unfortunate Mary Queen of Scots was doomed to close and rigorous confinement, after the battle of Pinkie, in 1567. For magnificence of expanse, richness of prospect, and pleasing sublimity of scenery, Loch-Lomond, in Dumbartonshire, stands unrivalled among the British lakes. It is 30 miles long, and nine at its greatest breadth, and is adorned with about thirty mountainous and romantic islands, supposed a continuation of the Grampian chain, which terminates on its western shores. At the south end its depth is seldom more than twenty, but north from the foot of Ben-Lomond is from sixty to a hundred fathoms. Eastward from this, in Perthshire, lies a group of lakes, imbosomed among those rugged and stupendous masses, called the *Trosachs*, forming a landscape which, for its rude and gloomy grandeur, exceeds all the powers of description. Of this group Loch-Catherine, ten miles long and one and a half broad, is the largest and most celebrated: Bold and rocky islands rise from its clear and unrippled waters. In the same county, Loch-Erne, eight miles long and one and a half broad; Loch-Tay, 15 miles long and two where widest; Loch-Rannoch, 12 miles long, and from one to two in breadth; and Loch-Ericht, 14 miles long and nearly one broad,—present in general a mixture of the soft and bolder features of nature. Loch-Awe, in Argyleshire, about 30 miles long, and two at its greatest breadth, contains a number of beautifully wood-tufted islands, and affords a view, perhaps the most picturesque of any to be met with in the kingdom. Inverness-shire boasts of Loch-Laggan, about 12 miles in length, and one and a half in breadth; Loch-Lochy, 14 miles long, and two where broadest; and Loch-Ness, 22 miles in length, and nearly three at its greatest breadth, and from 60 to 135 fathoms deep, surrounded with grand and magnificent scenery. There are many lakes in the three northern counties; but the enumeration shall here close with the mention of Loch-Mari, in Ross-shire, 16 miles long, and from one to two broad; and Loch-Shin, in Sutherlandshire, 20 miles in length and two at its greatest width.

Rivers.—The rivers which water and fertilize the island of Great Britain, are too numerous to be particularly noticed. By far the largest and most commercially important is the Thames, which originates in a copious spring on the confines of Gloucestershire, two miles south-west from Cirencester; and having received, in a circuitous course of 160 miles, seventeen tributary streams, falls into the British ocean between Kent and Essex, and is navigable for 130 miles. The Severn, from its rise in Plinlimmon mountain, takes a semicircular sweep through the counties of Montgomery, Salop, Worcester, and Gloucester, to the Bristol channel, into which it discharges itself, after increasing its waters by its junction with other rivers. It admits barges as far as Welch-pool. Commencing in the northern extremity of the Peak in Derbyshire, the Mersey flows in a north-westerly direction; is augmented in its progress by the Irwell near the village of Flexton, and by the Weaver at Frodham, where it forms a basin; and, for vessels of considerable burden, is navigable from Liverpool to the mouth of the Ir-

Statistics. well. The Humber, which mingles its waters with the ocean between the shires of Lincoln and York, is composed of innumerable streams flowing into it from various quarters; the principal of which are, the Trent, which rises in the moorlands of Staffordshire, and is navigable to Burton in the same county, and the Ouse, which has its source in the northern parts of Yorkshire, and is navigable to Rippon. From its origin in Stanmore, in Westmoreland, the Tees proceeds in a south-easterly course, dividing Yorkshire from Durham, and falling into the sea below Stockton, above which it is innavigable. The Tyne, formed by the meeting of two branches near Hexham, called the South and North Tyne, the one from the borders of Cumberland, and the other from the Cheviot-hills, empties itself into the ocean at Tynemouth, and affords water for vessels of moderate burden as far as Newcastle. Rising in Westmoreland, on the confines of Yorkshire, the Eden flows in a north-westerly direction until it enters the Solway firth, from which it is navigable to Carlisle.

On the south of Scotland, the Annan; springing from the Moffat hills, and passing through a tract of thirty miles, falls into the Solway firth; into which also the Nith, from the elevated land of Ayrshire, discharges itself. Tweedsmuir, in Peeblesshire, gives birth to the pastoral river Tweed, which, after its meeting with other streams, loses itself in the ocean at Berwick. The Forth has its source near the foot of Ben Lomond, and, moving onwards with many beautiful windings towards the east, and increasing its volume in its progress by the accession of the waters of Teath, Allan, and Ardoch, it expands below Alloa into a capacious firth of unequal width. Opposite to Limekilns it is *three* miles, to Queensferry *two*, to Leith *seven*, to Prestonpans *thirteen*, and to Dunbar *fifteen* miles in breadth. At its mouth lies the isle of May; and further up are the Bass, Inchkeith, Inchcolm, Cramond, and Inchgarvie. It is navigable to Stirling bridge for vessels of 30 tons, and to Grangemouth for ships of any burden. The river Clyde flows about 81 miles from its origin in the southern borders of Lanarkshire, and, opposite to Cowal in the county of Argyle falls into the firth which bears its name, forming in its course, in the vicinity of Lanark, those wonderful and stupendous cascades called the *Falls of the Clyde*, and affording an easy navigation for small-craft to the city of Glasgow. Issuing from its source in Braidalbin, in the western confines of Perthshire, the Tay, swelling as it moves along by the tribute of many streams from the mountains, pours into the sea, between the shires of Fife and Angus, a greater quantity of water than any other river in Britain, and admits vessels of considerable size as far as the town of Perth. The only other rivers of note which remain to be mentioned are the Dee and the Don, which, proceeding from the Grampian mountains on the west of Aberdeenshire, mingle with the ocean, the one at New, and the other at Old Aberdeen; and the Spey, which, from its rise in Badenoch in Inverness-shire, flows with a rapid current down its declining channel in a north-easterly course into the Moray firth.

Statistics. *Canals*.—The commercial interests of Britain are greatly promoted by means of numerous canals, which in the southern parts of the island run in almost every direction. Passing by Stroud to Lechlade, one joins the Severn and the Thames, and from the latter of these rivers canals stretch into various quarters. The Grand Trunk, uniting the Trent and the Mersey, was begun in 1760 and completed in 1777; it sends off many branches, and opens an important communication between most of the principal cities and towns in England. Another canal reaches from Chesterfield in Derbyshire to the Trent at Stockwith; another from Liverpool to Leeds, in a winding course of 117 miles, with an arm extending to Manchester; and a third from West Houghton in Lancashire to Kendal in Westmoreland. The earliest canal of which there is any authentic account, is that between Liverpool and the coal-pits at St Helens, for which an act of Parliament was obtained in 1755. But besides those now mentioned there are others in England, though chiefly of inferior consideration.

In Scotland the canals are but few, and of course inland navigation is conducted on a less extensive scale. The principal canal yet opened was finished in 1790, connecting the Forth and the Clyde, and affording a passage between the British and Atlantic oceans, for vessels not exceeding nineteen feet of beam, nor drawing more than eight feet of water. From it a branch, called the Monkland canal, runs twelve miles into the country, touching Glasgow on the north-east. Between this city and Ardrossan bay, by the way of Paisley, another has been long projected, but has hitherto been carried no farther than the village of Johnstown; and between Edinburgh and lock sixteenth of the Forth and Clyde canal, the Union canal, recently sanctioned by an act of Parliament, is to extend. In Argyleshire there is a small one about six miles long and nine feet deep, which joins Loch-Crinan with Loch-Gilp, an arm of Loch-Fine; and from Loch-Linnhe, the Caledonian canal, which is now in a state of considerable forwardness, proceeds through Loch-Lochy, Loch-Oich, and Loch-Ness to the Moray firth. Of this canal the surface width is 110, the bottom width 50, and the depth 20 feet.

Chap. III. Natural History.

The natural history of Britain opens up a wide field of interesting research; but the following observations on its different branches must of necessity be very general.

Meteorology.—Although the geographical position of the island be within the northern region of the temperate zone, yet it is by no means exposed to such extremes of heat and cold, as are experienced in parallel latitudes on the continents of Europe, Asia, and America. The cause of this mediocrity of climate is doubtless to be traced, partly to the shelter and reflecting surface of its mountains and hills; partly to the high state of cultivation at which it has arrived; and partly to the tepid breezes, wafted from the surrounding sea which bathes its shores. July and August are commonly the two warmest, and December and January the two coldest months of the year. The difference of temperature between England and Scotland, is chiefly observable with regard to the degree of heat in summer. According to Fahrenheit's thermometer, the mean annual temperature at London is about 51° 9′, the range of the annual variation being 61°, that is 31° 9′ below and 29° 1′ above the mean; leaving 20° for the lowest, and 81° for the highest degree of heat. At Edinburgh the annual mean is about 47½°, the lowest being seldom less than 20° and the highest seldom more than 75°, affording an annual range of 55°. In the vicinity of the former of these cities, the thermometer in June last (1817) stood in the shade at 84°, and in exposed situations at 113°; and in the neighbourhood of the latter at 82° in the shade, and at 107° in exposed situations. This is the greatest heat which has been known in Britain since 1808, when at London the thermometer rose nearly to 90°, and at Edinburgh to 82°.

More *rain* falls in the western than in the eastern parts of the island; and although it be impossible to ascertain precisely the real quantity which annually occurs, yet the indications of the rain-gauge kept at different places, may serve to give some idea of their relative moistness. At Liverpool the annual average is 34.4, at Keswick 68, at Kendal 64, near Leeds 27.5, and at London 23 inches; at Largs, near the mouth of the Clyde, 39.7, at Greenock 32.4, at Glasgow 28.3, at Edinburgh 25.3, but at the top of Nelson's monument only about 15.3, and at Gordon castle 25 inches. According to Sir John Sinclair's General Report of Scotland, the difference of fair weather throughout the year, in favour of the eastern coast, is seventy days.

The state of the barometer tends to confirm the above indications. From the greater humidity of the atmosphere the mercury usually stands lower at Kendal than at York or London, and lower at Greenock than at Edinburgh or Dalkeith. Its mean annual height in Britain is about 29.8; it seldom rises higher than 30.5, nor sinks lower than 28.5; having a range of about two inches. A drizzling *mist* sets in, and heavy *dews* begin to fall in spring; and evaporation, which is very considerable, is three times greater from the 21st of March to the 21st of September, than during the rest of the year.

In Britain the most prevalent *winds* are those from the west; and to this circumstance is to be ascribed the quantity of rain which deluges its western parts, where the mountains intercept the clouds charged with vapours from the Atlantic ocean, and nearly deprive them of their contents before they reach the east. At London the wind blows, on an average during the year, 215 days from the west, and 116 from the east; from the south 18, and from the north 16 days. It appears from 620 observations made in the vicinity of Edinburgh, that in the year ending 16th November 1816, the wind blew 185 days from the west, and 112 from the east; from the south 18, and from the north 26, with 25 days variable; and that from the 16th November 1816, to the 28th July 1817, the wind blew 165 days from the west, and 63 from the east, from the south 9, and from the north 3, with 14 days variable. The westerly winds are the highest, the most regular, and the most salubrious.

As to the electrical phenomena of the island, *thunder* and *lightning*, which seldom do much mischief, generally occur during the summer months, between May and September, although they sometimes happen even in December and January. Until the beginning of the 18th century the *aurora borealis* rarely appeared; and its brilliant and beautiful coruscations, which subsequently to that period had often excited attention, have since 1793 been less frequently observed.

Zoology.—According to Mr Pennant there are twenty genera of *animals* in Britain, besides those which are now extinct. The island, at an early period of its history, could enumerate among its quadrupeds, the buffalo, the bear, the wolf, and the wild boar; but these, since the woods in which they ranged have so generally yielded to the hand of cultivation, have long given place to others of a domestic and more useful kind. If we except the red deer and roe-buck, which still bound over the Highlands of Scotland, the wild quadrupeds which are at present to be found are of a less size; such as the fox, the badger, the martin, the otter, the hedgehog, the hare, the squirrel, the mole, the rat, and the mouse. The horse, undoubtedly the noblest animal over which man has extended his conquests, is met with in great perfection, and of different breeds. Oxen and sheep of various casts, and of every degree of excellence, graze on the richest pastures; but the indigenous horned-cattle, which are long-legged, of a pure white colour, with black muzzles, &c. exist only in Needwood forest in Staffordshire, at Chillingham castle in Northumberland, and in Hamilton wood in Lanarkshire. Of the hog, which forms a part of the stock of almost every farmer, and also of the domestic species of the dog kind, there are great varieties. The goat, an inhabitant of the rocks, is common in the mountainous districts; and the sea-calf and great seal are frequently to be seen on the surrounding coasts.

The *ornithology* of the island consists of 48 genera; of which the bustard is the largest, and the golden-crested wren the smallest bird. The nightingale, peculiar to England, is confined chiefly to the eastern and midland counties, and is seldom observed farther north than Doncaster, in the west riding of Yorkshire. All the domestic birds seem to be of a foreign origin; the poultry from Asia, the Guinea fowl from Africa, the peacock from India, and the pheasant from Colchis in Asiatic Turkey. There are four genera of reptiles; namely, the frog, the lizard, the serpent, and the snake. And, abstracting from those called crustaceous, there are 40 genera of fish. The whale sometimes appears in the circumambient sea, but the basking shark is often seen playing on the western coast. Some of the most excellent of the edible among the finny tribe, are the turbot, the salmon, the cod, the smelt, the mullet, and the skate.

Botany.—From the lofty pine, which waves in the forest, down to the humblest vegetable that creeps on the ground, the Flora of Britain is highly interesting to the botanist. It consists of about 2000 plants and the discoveries of every succeeding year are adding to their number. Of these, besides grasses, ferns, and sea-weeds, some are *leguminous*, some *umbelliferous*, some *bulbous*, some *rosaceous*, some *radiated*, some *evergreens*, and others *deciduous*. Most of them are common to England and Scotland, although each country contains a few peculiar to itself. But as our limits forbid us to enter at large into the subject, and as no useful purpose could be served by a partial or mutilated view of it, the reader who may wish a description of the generic and specific characters of our indigenous plants, is referred to Smith's *Flora Britannica*, or *Withering's Botanical Arrangement of British Plants*.

Mineralogy.—Great Britain presents a wide field of investigation to the mineralogist. All the varieties of primitive and secondary rocks are met with; coal, which gives life and vigour to her manufactures, is abundant in many places; and the more useful metallic ores may be enumerated among her mineral treasures.

Primitive rocks.—Granite is the common rock in Cornwall, is sparingly found in some of the interior districts of England, and occupies the central parts of some of the mountains of Scotland, as in Galloway, the Grampians in the north, and in the islands of Arran and Mull on the west. Gneiss, or schistose granite, is less frequent, but appears on the sides of the Grampians and in the islands of Coll and Tirie. Micaceous schistus is the prevailing rock on the flanks of the mountains in some of the islands of Scotland, as well as in some of the central regions; and common slate is abundant both in England, Scotland, and the islands. Scotland affords some varieties of primitive limestone, or marble, which are not destitute of beauty. Serpentine appears in Cornwall and at Portsoy, nearly at the extremities of the island. Porphyries of the primitive class are occasionally met with; syenite forms extensive beds in Islay and on the western coasts of Ross-shire; and quartz rock composes the central range of the mountains in Islay and Jura.

Secondary rocks.—Of the secondary rocks the grey wacken of the Germans occupies a great extent of the southern districts of Scotland; and it is not an uncommon rock in some of the northern parts. All the varieties of sandstone are common; gypsum, or plaster of Paris, is frequent in some parts of England, but rare in Scotland; and the extensive deposition of rock-salt in Cheshire has been long wrought. Chalk is abundant in England, but is unknown in Scotland. A range of chalk hills begins at Flamborough-head in Yorkshire, and runs in a westerly course for the distance of twenty miles; two ridges traverse the middle counties, and approach nearly to the borders of Oxfordshire; and on the south side of the Thames a ridge commences at the North and South Foreland, passes through Kent and Surrey, and terminates in Hampshire; and another ridge begins near the lofty promontory of Beachy-head, and passes through Sussex and the south of Hampshire into Dorsetshire.

Coal.—Coal is far from being universally distributed in Great Britain; two great belts of coal traverse the island from sea to sea. The first great belt, of which the Newcastle and Whitehaven coal-fields form the extremities, crosses the northern district of England; and the great belt of coal in Scotland occupies the vallies of the Forth and Clyde, and the adjoining districts. Beside these extensive depositions, coal is abundant in the counties of Stafford, Derby, Gloucester, and South Wales; and in Scotland, in small patches in the counties of Dumfries, Argyle, and Sutherland.

Metallic ores.—Great Britain furnishes some of the more useful metallic ores in great abundance. The search for gold, and the operation of separating it from the alluvial soil in which it was found, were carried on in the mining district of Leadhills in Scotland during the reign of Queen Elizabeth, and, it is supposed, by persons sent from England; they were resumed on a large scale at a much later period, but, excepting as an amusement, are now entirely discontinued. Excepting a few globules of native mercury, which were discovered in a bed of clay in digging the foundation of a house at Berwick-upon-Tweed, none of the ores of that metal has been found in Britain. Silver ores are rare in this country. Some of the lead ores afford a considerable proportion of silver; and the mines of Cornwall yield a small quantity of the native metal. From L.40,000 to L.50,000 worth of silver were obtained from a vein in the parish of Alva, in the county of Stirling in Scotland, before it was finally exhausted, but the researches made to recover it proved fruitless. Valuable copper mines have been long wrought in Cornwall, in Derbyshire, and in Wales; but although appearances of copper ores are not unfrequent in Scotland no productive mines have been opened up. Iron ores are abundant in many places; and lead mines have been long wrought in different places of England and Scotland. Tin has never been discovered in any part of Britain excepting in the mines of Cornwall, which were known from the earliest ages, and are still productive. The ores of zinc are common in some of the lead mines; and antimony has been met with in Cornwall and Devonshire; but the greatest repository of that metal is in Dumfries-shire. Cobalt is rare in Britain, but some of its ores have been found in considerable quantity in Cornwall, and in the copper mine of Alva in Stirlingshire in Scotland. The chief source of manganese, a valuable commodity in various manufactures, is in Devonshire; and a vein of the same metal was discovered some years ago in the primitive rocks of Aberdeenshire.

Chap IV. Soil and Agriculture.

In an extent of surface so great, and so diversified by hill and dale, as that of Britain, a variety of soil is naturally to be expected. Some tracts, accordingly, present clay and loam; others chalk and calcareous earth; and others gravel, sand, and moss. Good and productive soil is most prevalent in the southern, midland, and eastern counties. The proportion of waste to cultivated lands is greater in Scotland than in England and Wales, arising from the sterility of its numerous bleak and shelterless mountains, which must ever bid defiance to the efforts of human industry and improvement. Of the

Statistics.

38,498,572 acres which the southern division of the island is computed to contain, about 7,787,000 are waste, and nearly 31,000,000 are either cultivated or planted with useful timber. The northern division, including its islands, is estimated at 19,352,320 acres, of which about 13,900,000 are waste, and 5,452,320 are either cultivated or covered with valuable wood.

The art of husbandry seems to have been first practised in the south-eastern corner of the island; but at what period it was formed into a regular system is not certainly known. During the Roman possession, as early as the third century, considerable progress in this art was made; woods were hewn down, and marshes were drained. From that era agricultural improvements have advanced, sometimes with slower, and at others with more rapid steps, to its present state. These improvements have been promoted by the exertions of several distinguished proprietors, the writings of different individuals of great professional eminence, and the zeal and encouragement of the British Board of Agriculture. The value of the whole land produce of England, according to Mr Arthur Young, in his Agricultural Report of Essex, is L.145,800,000,—and of Scotland, according to Sir John Sinclair, in his General Report, L.23,261,155, making a total for Britain of L.169,061,155. In no country of the world is agriculture carried to greater perfection; the preparation of the ground, the rotation of the crops, and the mode of conducting every branch of rural economy are well understood. See Agriculture.

The *horticulture* of the island is not inferior to its agriculture. By this art in the raising of culinary vegetables, the rich and delicate fruits of more southern latitudes, and other productions of the garden, the defects of the climate are in some degree compensated, and the tables of the wealthy are loaded with luxuries.

Chap. V. Inhabitants.

Respecting the first inhabitants of Great Britain, the most probable opinion is, that they migrated from Gaul, at an early period, when but one race of men existed in western Europe. And, indeed, the declarations of Cæsar and Tacitus as to the identity of the people of those two countries, tend powerfully to confirm this opinion. The Celtic tribes, who settled on the southern shores, would gradually move northward, as they were prompted by curiosity or by interest, until they at length diffused their population over the whole island. Accordingly, we find that the same worship, and manners, and language, prevailed in both of its local divisions; and these furnish proofs, " which," says Mr Chalmers in his Caledonia, " demonstrate the sameness of the people with greater conviction than the fanciful theories of philosophers, or the absurder intimations of ignorant chroniclers."

Present state.—But by foreign intermixture the inhabitants, if we except the Welsh and the Scotch Highlanders, who still retain their original characteristics, soon lost their national and distinctive features. To their Celtic blood was added an infusion from that of their Roman, Saxon, Danish, and Norman invaders; and in later times the confusion of races has been considerably increased by an influx of strangers from different countries, impelled thither by the motives of safety, commerce, or employment. Hence it is, that while the language which is now spoken has for its basis a dialect of the Teutonic tongue, it is much indebted for the copiousness which it displays to most of the other languages of Europe, from which it has so liberally borrowed its treasures.

Statistics.

Character.—The British, generally considered, are well made, brave, and generous. They are inclined rather to be taciturn than loquacious; and although impatient of controul or of insult, they are far from being implacable when offended. No people rank higher in a moral and intellectual point of view, or evince greater vigour of mind, and observe more correctness and integrity in their conduct. If their imagination be not so sprightly and luxuriant as that of their neighbours, who enjoy a purer and serener atmosphere, their judgment is at least more solid, and their ratiocinations more profound. In the departments of history and of metaphysics they stand unrivalled.

Number.—The population of Great Britain has since the Revolution been gradually increasing, as will appear from the following statement:

England in	1688 contained	6,500,000 inhabitants.
	1786	8,000,000
	1801	8,872,980
	1811	10,106,780
Scotland in	1755	1,266,380
	1799	1,526,492
	1801	1,599,068
	1811	1,804,864

Thus, according to the last return, the population of the whole island is 11,911,644; and if to this number we add 640,500 for the army, navy, &c. the aggregate sum will be 12,552,144, or somewhat less than one person for every four acres.

Chap. VI. Manufactures, Commerce, Revenue, &c.

Great Britain, in respect of the excellence of her manufactures, the extent of her commerce, and the magnitude of her revenue, surpasses every other country in Europe, if not in the world.

Manufactures.—In consequence of the division of labour, the application of improved machinery, and other contributory causes, the manufactures have arrived at great perfection. Woollen cloths and kerseymeres of the finest quality are made in different counties of England, such as Wilts, Somerset, and York; and stuffs of various kinds are fabricated in Norfolk, Suffolk, Essex, Leicester, Nottingham, Montgomery, and Denbigh, and in some places of Scotland, especially the shires of Selkirk and Stirling.

The *cotton* manufacture, which is of more recent origin, is now carried on very extensively in different districts of the country. Its principal seats are, Stockport, Manchester, Bradford, Carlisle, Glasgow, and Paisley. To facilitate the process of weaving, and to improve the quality of the texture, many ingenious mechanical inventions have been employed; and, in respect of variety and elegance, there is no sort of goods in which the superiority of the British fabric is more apparent and generally acknowledged. *Linen*, of various descriptions, is wrought in Scotland and the north of England; and the manufacture of silk, begun about the middle of the 15th century, and afterwards greatly promoted by the French refugees in 1685, is very considerable at Spitalfields, Coventry, Leek, Ockingham, and other towns in South Britain.

In point of excellence, the different branches of *metallic* manufacture cannot be surpassed. At London and Edinburgh, especially the former, the most accurate and finished mathematical and optical instruments are executed; besides a variety of workmanship in gold, silver, and jewellery. Locks, hinges, polished steel, cutlery, plated goods, and different kinds of tools, unrivalled for their beauty and their cheapness, are produced at Birmingham and Sheffield. Porcelain, of the finest patterns and in the most exquisite taste, is made at Worcester, Derby, and Colebrookdale; and potteries of earthen ware are common throughout the island, although the preference is generally given to the ware of Staffordshire. In addition to those now enumerated, there are many other manufactures, such as glass, paper, hats, leather, gunpowder, copperas, white-lead, soap, and turpentine.

Commerce.—Great Britain, from the excellence of her manufactures, the advantages of her insular situation, and her ascendancy in the scale of nations, is well fitted for carrying on an extensive trade. Claiming the dominion of the ocean, she spreads her ships over its surface, and, possessing almost universal commercial relations, lades them with the riches of the world. On the 30th September 1813, her merchant-vessels were 19,315 in number; of which 16,602 belonged to England, and 2713 to Scotland, bearing, in all, 2,260,910 tons, and manned with 144,673 seamen, including boys. To give some idea of her traffic, a table is here subjoined, shewing the official value of her exports at different periods, and distinguishing her own produce and manufactures from her foreign and colonial merchandise.

Year.	British.	Foreign.	Total Exports.
1792...	L.18,336,851	L.6,129,998	L.24,466,849
1796...	19,102,220	8,923,848	28,026,068
1800...	24,304,283	13,815,837	38,120,120
1804...	23,935,793	10,515,574	34,451,367
1808...	26,691,962	7,862,305	34,554,267
1815...	44,053,455	16,930,439	60,985,894
1816...	36,714,534	14,545,933	51,260,467

From the numerous regions to which Great Britain extends her commerce, she imports goods of various descriptions; and, on an average of many years, the balance of trade has been very considerably in her favour.

Her principal imports from the continent of Europe are, hides, furs, silks, cambrics, wool, carpets, flax, tallow, bar-iron, tar, pearl and pot-ashes, drugs, gums, dye-stuffs, corn, cheese, butter, fruits, wines, geneva and brandy;—from Asia, tea, spices, opium, drugs, gums, saltpetre, quicksilver, raw silk, cotton, and various products of the loom;—from Africa gold-dust, gums, and ivory;—from North and South America, flour, rice, tobacco, timber, indigo, and furs;—and from the West Indies, sugar, rum, coffee, pepper, ginger, drugs, cotton, and mahogany.

Revenue.—The chief sources from which the revenue of Great Britain is derived are two, the Permanent and War Taxes. To the first of these belong the duties of customs and excise, the stamp-duties, the post-office duties, the land and assessed taxes, and some miscellaneous taxes; and to the latter are referred those occasional taxes which are rendered necessary by extensive and protracted hostilities, as, for instance, the property-tax, imposed during the late struggle with revolutionary France. With the growing prosperity and demands of the country, the annual revenue, arising from these different branches, has likewise increased,—as will appear from the following statement:

Year.	Net revenue.
1812...............	L.60,866,652
1813...............	63,763,864
1814...............	65,429,981
1815...............	66,443,802
1816...............	57,360,694

When the public income is too small to support the public expenditure, extraordinary grants, called aids, subsidies, or supplies, are usually voted. Out of the revenue resulting from the permanent taxes, the interest of the national debt is discharged; a debt which, since its commencement with L.5,000,000 in 1697, was, in 1816, about L.800,000,000. To pay it off, a sinking fund, planned by Mr Pitt, was instituted in 1786.

Army and Navy.—In the year 1801, Great Britain maintained 149,865 regular troops; and in 1814, which witnessed the first promise of the liberation of Europe from French tyranny and oppression, upwards of 247,500 troops, including cavalry, foot-guards, infantry, and militia. But since the decisive victory at Waterloo in 1815, their numbers, which have been much reduced, are not so easily ascertained; although, on a rough guess, they may be stated at about 110,000. The Navy, which has long been the glory and the bulwark of the nation, amounted in 1784 to 496 ships; in 1801 to 787; in 1814 to 1022; and in the present year, 1817, to 503, of which 151 are of the line.

Chap. VII.—Civil and Ecclesiastical Constitutions.

It has been observed by the Abbe de Condillac, that "Every state is more or less happy in proportion as its laws approximate to the impartiality of nature." This remark, when applied to Great Britain, points out the excellence of her civil and ecclesiastical constitution, which, being founded on principles of justice and of freedom, regards, with as jealous an eye, the rights of the lowest as the highest of its subjects, and procures for all, over whom it extends its authority, a greater sum of prosperity and happiness than perhaps that of any other nation.

Civil Constitution.—In 1603 both kingdoms became subject to the sway of one sovereign; but it was not until 1707, that the Scottish was merged in the English legislature. Of these kingdoms thus united, the government, which has long excited the admiration and the envy of foreigners, is of a mixed character, being composed of three branches, the King, the Lords, and the Commons. Each of these branches operates as a check upon the other, and prevents all encroachments on the constitutional rights of the nation. With the King, whose crown is hereditary, and whose person is held sacred, the executive power is lodged. His are the prerogatives of making peace and declaring war; of sending and receiving ambassadors; of forming treaties and alliances; of levying armies and fitting out fleets; of disposing of all magazines, castles, forts, havens, and ships of war; of nominating all the great officers of the state and of the household; of summoning, adjourning, proroguing, and dissolving Parliament; of confirming or rejecting any bill to which his sanction is requested; of conferring all titles of rank and honour; of pardoning criminals, or mitigating their punishment; and of managing the coinage, and determining its alloy, its weight, and its value.

The Lords and the Commons, convoked by writs from the King, to deliberate on the affairs of the state, compose the national Parliament, which is divided into what is called the Upper and the Lower Houses. The nobility, who occupy the Upper House, are distinguished into the Lords Spiritual and Temporal; the former consisting of two archbishops, and twenty-eight bishops; and the latter, of those who are peers by descent, by creation, or by election. In the Lower House sit the Commons, of whom there are 658, elected from among the knights, the citizens, and the burgesses, respectively representing counties, cities, and burghs.

The House of Lords is the highest court of justice in the realm, and from its decisions there is no appeal. The House of Commons is the grand inquest of the nation, and with it all grants of subsidies, and all bills, which more immediately affect the interests of the people, must originate. Freedom of speech, and protection from all arrests, except for treason, felony, or the publishing of seditious libels, are among the peculiar privileges common to both houses of Parliament.

In all essential points, the present constitution of Parliament was marked out, as early as the reign of King John, in the great charter of their privileges which his barons compelled him to sign in the year 1215. The Lords and the Commons originally met in the same place; but at what particular period the separation of the one from the other was effected is uncertain. Every act must first be presented in the shape of a bill, which after passing, in due form, through both houses, and receiving the sanction of the crown, is converted into a law. It would be entering on too wide a field, to describe here the character and functions of the different offices of state, or of the different courts of justice. Some account of these will be found under their proper titles.

Ecclesiastical Constitution.—In South Britain, the established form of ecclesiastical government is diocesan Episcopacy; the mode of worship is liturgic; and the creed, as unfolded in the thirty-nine articles, embraces the doctrines of the Calvinistic system. The King who, since the time of Henry the VIII. has been styled the head of the church, nominates to the vacancies in all episcopal sees. Properly speaking, there are only three orders among the clergy, namely, bishops, priests, and deacons; but the titles of archbishop, dean, prebendary, canon, &c. are also acknowledged. There are two archbishops, those of Canterbury and York, the former of whom is the primate of all England, the first peer in the realm, and next to the royal family; and there are twenty-four bishops, who enjoy the privilege of peers, besides the bishop of Sodor and Man, who has no seat in the House of Lords. Among the church courts are the convocation, now merely nominal, the court of delegates, the court of arches, and the court of audience. In all there are 1881 parishes, 2533 churches and chapels, and, it may be added, 3,438 dissenting places of worship. The average livings, taking in the higher and lower clergy, are about L280 annually.

Since the revolution in 1688, the Presbyterian form of church government has been established in North Britain. In this division of ecclesiastical polity, the most distinguishing principles are parity among the clergy, and the absence of all prescribed forms. The creed, as embodied in the confession of faith, and larger and shorter catechisms, is purely Calvinistic. Church sessions, presbyteries, provincial synods, and the general assembly, are the order of the ecclesiastical courts, proceeding from the lowest to the highest. There are 893 parishes, and 928 churches and chapels on the establishment, to which belong 1,408,388 individuals; and there are 397,300 dissenters of different denominations. The average livings are about L.200 annually, without allowing for manse and glebe.

The reader who wishes to pursue the preceding subjects farther, may consult Pinkerton's and Playfair's *Systems of Geography;* Aikin's *Geographical Delineations*; Chalmers' *Caledonia*, and his *Domestic Economy of Great Britain and Ireland*; Campbell's *Survey of Great Britain*; Wedderburn's *View of England;* and Sir John Sinclair's *Statistical Account*, and his *General Report of Scotland.*

PART II. CIVIL HISTORY.

In the following sketch of the history of Great Britain it is proposed, *1st*, To take a view of the history of England from the earliest times to the union of the crowns of England and Scotland; *2d*, Of the history of Scotland preceding the same era; and *3d*, The history of Britain from the union of the crowns to the present times, forming three separate chapters.

Chap. I. History of England.

Fabulous accounts.—The early history of this country, as of most other nations, is obscure, unauthentic, and, it might be added, uninteresting, if this did not impeach the judgment of our great dramatist, to whom it furnished materials for one of the finest exertions of his muse, and if the example of another poet, of no less splendid fame, did not assign a reason and an apology for avoiding such an imputation. Speaking of the generally, but not universally distrusted, relations respecting the most ancient affairs of the island, Milton does not hesitate to declare both his intention and his inducement to repeat them. "Seeing, (says he,) that oftimes relations heretofore accounted fabulous, have been after found to contain in them many footsteps and reliques of something true, as what we read in poets of the flood and giants, little believed, till undoubted witnesses taught us that all was not feigned; I have therefore determined to bestow the telling over even of these reputed tales, be it for nothing else but in favour of our English poets and historians, who by their art will know how to use them judiciously." To these, indeed, and to all "fables which are commonly employed to supply the place of true history," the authority of Hume prescribes an entire disregard; but the terms of his interdict, it will be seen, imply an assumption, not altogether warranted by the circumstances of the case,—that falsehood is substituted for truth; and, besides, he himself admits an exception in favour of the ancient Grecian fictions, for a reason that is totally destructive of the principle contended for—their being so *celebrated* and so *agreeable*, "that they will ever be the object of the attention of mankind." In place of such partiality and such indifference, on the mere ground of more or less pleasure from their perusal, it is an essential duty of the historian to rescue and to sustain what is probable, though it be neither certainly true nor yet agreeable and celebrated, from the contaminating mass of obvious absurdities and unaccredited legends. With this intention, therefore, a brief recapitulation of some "reputed tales" is now offered to the reader's attention. They are assuredly not employed to supply the place of true history, for nothing deserving that title exists, respecting this period, to be injured by so humiliating a preference; and though not, perhaps, equal to Grecian fictions, they have nevertheless a connection with the sentiments and the literature of our ancestors, which ought at least to exempt them from annihilation.

Samothes, Albion, &c.—The vanity of some of their own writers, anxious for the imaginary honour which antiquity confers, availed itself of unworthy and fictitious authors to carry back the establishment of the original inhabitants of England to a Samothes, or Dis, a fourth or sixth son of Japheth, whom they assert to have planted colonies about 200 years after the flood, first in Celtica, or Gaul, and afterwards in this island, thence named Samothea, where he reigned, and from whom descended four kings, Magus, Saron, Druis, and Bardus. Nothing but the most determined credulity could have listened to a fabrication so totally unfounded and so improbable. A branch of this story bears, that the inhabitants of Samothea were subdued in the reign of Bardus by Albion, a giant, and son of Neptune, who gave the island his own name, and ruled in it for forty-four years, when, having gone over to Gaul to assist his brother Lestrygon, whom Hercules was hastening out of Spain to attack, he was slain in battle.

In part of this, properly interpreted, there is a shadow of meaning not unworthy of regard, though too general in its import to satisfy national partiality,—that a navigator and a man of power, so named, having visited the island some time after it had been peopled, made a settlement in it, and obtained authority among the former inhabitants. Certain it is, that both Greeks and Romans anciently styled the island Albion; and that some authors make mention of a place between Arles and Marseilles, in France, where the chief so named, and his brother Bergion, or, as others have it, Dercynus, lost their lives in a contest with Hercules, and to which, from the circumstance, as it is related, of this semi-deity being favoured with a shower of stones during the battle, but rather owing to its abounding in rocks, the epithet of *stony*, or, in the Celtic tongue, the title of the *crag*, or *craig*, was afterwards applied.

Dioclesian's daughters.—"Too unconscionably gross," to use the language of Milton, is another and a fond invention, that "wafted hither the fifty daughters of a strange Dioclesian king of Syria." This is a patriotic, but very unwise adaptation of the well known, though totally apocryphal story of Danaus, king of Argos, and, like it, does equal injustice to the fair sex. The whole number of the ladies, with the exception of one, it is vilely reported, murdered their husbands on the night of their marriage,—a summary cruelty, which no doubt richly deserved their being "turned out to sea in a ship *unmanned*," as the poet has it, "of which whole sex they had incurred the hate." Fortune, or the fates, according to the story, drove them to this island, "where the inhabitants, none but devils, as some write, or, as others, a lawless crew left here by Albion, without head or governor, both entertained them and had issue by them, a second breed of giants, who tyrannised the isle till Brutus came." From the eldest of these nefarious damsels, called Albina, says the legend, the name of Albion was derived.

Story of Brutus.—"Hitherto the things themselves have given us a warrantable dispatch to run them soon over." The attempt to obtain a Trojan origin for our ancestors, so that in one thing, at least, we might resemble the Romans, unlikely and unsuccessful as it may have been, has had too many admirers, and is too seducing to common minds, to be so readily discharged. Whether certain or uncertain, such a report, if it "keep aloof from impossible and absurd, and be "attested by ancient writers, from books more ancient," is not to be refused "as the due and proper subject of story." The authors who have chiefly mentioned it are Geoffry of Monmouth, Henry of Huntingdon, and Matthew of Westminster.

Brutus, son of Sylvius, the grandson of Eneas, whose piety and wanderings are blazoned by the prince of Latin poets, having the misfortune, according to prophetic intimation, to occasion the death of both his parents, some time after the establishment of the Trojans in Italy, was induced, at the instigation, or by the dread of his kindred, to retire into Greece. Here he met with some of the descendants of Helenus, son of Priam, in a state of slavery under king Pandrasus. Ingratiating himself with them, and obtaining their confidence, he is induced to become their leader in an attempt to recover freedom, which having accomplished, after various difficulties, the display of courage and subtlety, and acquiring the king's eldest daughter, Innogene, in marriage, he sets sail with the Trojans in a fleet of 324 vessels. A voyage of two days and a night brings them to a certain island, named Leogecia, now unknown, and at that time dispeopled and laid waste. Here a temple and image of Diana being discovered, it was determined that Brutus should solicit an oracular response as to the future course to be pursued. The goddess, propitious to his wishes, answered him in a vision:

"Brutus, far to the west, in th' ocean wide,
Beyond the realm of Gaul, a land there lies;
Seagirt it lies, where giants dwelt of old,
Now void, it fits thy people; thither bend
Thy course, there shalt thou find a lasting seat;
There to thy sons another Troy shall rise,
And kings be born of thee, whose dreaded might
Shall awe the world, and conquer nations bold."

Thus encouraged, Brutus again sets sail in the direction suggested. During his course, he arrives at a place in the Tyrrhene sea, where he finds the offspring of those of his ancestors who had come into Italy with Antenor. These, under Corineus, join him. He now passes the straits of Hercules, and casts anchor on the coast of Aquitania in Gaul, where he sustained considerable loss in several engagements with king Goffarius, particularly that of his nephew Turon, from whom the city of Tours had its name. This calamity, and his recollection of the oracle, induce him to leave the country; and, accordingly, prosecuting his voyage, after an easy course, he arrives at the promised island, near the spot where the town of Totness now stands, in the county of Devon. The only remaining inhabitants, at this period, were some giants of the race of Cham, who of course are slain, after which Brutus divides the country among his followers. He himself reigned over the whole island for twenty-four years, when he died, and was buried in the city which he had founded, Troja Nova, afterwards denominated Trinovantum, and now London, having bequeathed his dominions to his three sons, viz. Loegria, the same as modern England, exclusive of Wales, to Locrin, or Loegrin, his eldest; Cambria, or Wales, to Camber, whose name it inherited; and Albania, since called Scotland, to Albanact, the youngest. These events are related to have occurred about 1200 years after the flood, and upwards of half a century from the destruction of Troy.

Locrine,—in whose fortunes we are most concerned, though contracted in marriage to Guendolen, daughter of Corineus, long held illicit commerce with Estrildes, the daughter of a king of Germany, remarkable for her beauty, and whom he had made captive in an engagement with Humber, king of the Hunds. On the death of Corineus, whose authority he feared, Locrine divorces Guendolen, and proclaims Estrildes queen. The former flying into Cornwall, where her son, Madan, had been brought up by his grandfather, gathers her fathers friends and subjects, with whom she makes war on Locrine, gives him battle, in which he loses his life, and following up her success and revenge, throws both Estrildes and a daughter whom she had born to him into a river, which thence took the name of the latter, Sabra, but was afterwards changed to Sabrina, or Severn.

Madan, Ebranc, &c.—After a reign of fifteen years, Guendolen resigned in favour of her son Madan, who ruled prosperously and in peace for forty years, and left two sons, Mempricius and Malim, by no means so fortunate. The former dreading the ambition of his brother, treacherously slew him, but afterwards reigned ingloriously, and was at last devoured by wolves. His son, Ebranc, succeeded, and reigned forty years in no small splendour. He is said to have carried on a predatory war in Gaul, and, after his return with great riches, to have laid the foundation of two celebrated cities, Caerebranc, now York in England, and Alclud, Mount Agned, or the Castle of Maidens, the ancient title of the metropolis of Scotland. After him, in succession, reigned a second Brutus, who carried on his father's wars abroad; Leil, a peaceable man, whose latter years were troubled with civil discord; Rudhuddibras, or Hudibras, the alleged founder of Caerkeynt, now Canterbury, Caerguent, now Winchester, and Mount Paladur, now Septonia, or Shaftesbury, as his father was of Cairleil, now Carlisle; and Bladud, an ingenious and skilful man, who is said to have built Caerbadus, now Bath, and to have dedicated its medicinal waters, already celebrated, to the goddess Minerva.

King Lear's fortunes, &c.—Then succeeded Leir, or Lear, part of whose eventful history is immortalized by the genius of Shakespeare. This amiable but imprudent man, feeling the infirmities of age creep upon him, and having no son, resolves to divide his kingdom among his three daughters, not indeed equally, but with some respect to the largeness of their professed affections towards him, as ascertained by simply questioning them in order. In this foolish trial, the sincere but unostentatious regard of the youngest, Cordellia, previously his favourite, and from whom he expected the most zealous declaration, excites his indignation, in consequence of which he disinherits her, sends her into banishment, and having given the other two daughters in marriage to Maglaunus, duke of Albania, and Henninus, duke of Cornwall, divides between them one half of his territories, promising the remainder at his death. Their piety, little promoted by their pompous flattery, does not prevent them from encroaching on his authority, and at last depriving him of every portion of his kingdom. Repeated indignities and acts of aggravated cruelty, apparently concerted to drive him to despair and death, at last convince him of the injustice and folly of his decision. Then the remembrance of his youngest child, whose candour and good sense he had despised, awakens a ray of hope, mortifying as it was, that her love towards him "being what her duty bade," might form as great a contrast to that of her sisters, as her modesty did to their fulsome protestations. The far-famed wisdom and graces of this excellent lady had ere now obtained for her the esteem and the hand of a great king in Gaul, whither, Lear, overwhelmed with distress, takes his journey. He is received in a manner fitting his misfortunes and her own character; and such is the regard and the confidence of her husband, that an army is immedidiately appointed to aid in recovering his throne. Their enterprise is fortunate; Lear reigns again for three years, and is succeeded by Cordellia in her own right for five years, when she is deposed and imprisoned by Marganus and Cunedagius, her sister's sons. These part the land between them, but soon quarrel. A battle ensues, in which the former perishes. Cunedagius now reigns alone for many years, about the time when Rome was built. His son succeeds him; and the line of Brutus is carried on for several generations without any very remarkable occurrence.

Contest of Belinus and Brennus.—On the extinction of this race, the land is rent into five kingdoms, which continue at war with each other for about fifty years, but is at last reduced under one head by Dunwallo Molmutius, son of Cloten, king of Cornwall, and the first person who is said to have worn a crown of gold in the island. He is said to have established a system of laws long after famous, and, in a reign of about forty years, to have given a degree of civilization and improvement to his country which it had never previously known. His two sons, Belinus and Brennus, after a contest for the crown, agree to a mutual participation of the land, vesting, however, the sovereignty in the elder. But this last concession soon proves disgusting to Brennus, who accordingly goes to Norway, where he forms an alliance with king Elsing, and obtains a fleet to support his ambitious pretensions. This was attacked on its way to Britain, by Guithlac, a Danish king, actuated by motives of jealousy, and a wish to obtain the wife of Brennus. The battle appears to have been disastrous to both parties, the fleet of Brennus being scattered, and the Danish king, after having got possession of his lady, being driven on the coast of Northumberland, where he is made prisoner, and whence, together with her, he is brought to Belinus. Collecting again his navy, Brennus resumes his enterprise, lands in Scotland, gives battle to his brother, is completely defeated, and obliged, with one ship, to flee into Gaul, where, in course of time, he acquires the friendship of Saginus, duke of the Allobroges, whose daughter he marries, and to whose dominions he latterly falls heir. By this success, and through the aid of several kings of Gaul, he thinks himself more able than ever to gain a settlement in his native country, now peaceably and wisely governed by his brother. With great force, therefore, he lands in Britain, and finding Belinus totally unprepared, promises himself certain victory, when, on the very eve of battle, his aged mother, Conuvenna, appears on the field, throws herself between the two brothers, and by the most forcible appeals to affection, duty, and respect, accomplishes an entire reconciliation.

Barbirus said to have peopled Ireland.—Now joining hands and forces together, Belinus and Brennus prepare for foreign conquests. In a little time they over-run most of Gaul, and actually push into Italy, where they give no small annoyance to the Roman state. Belinus at last returns home, reigns in peace and honour, builds various cities, beautifies the metropolis with a gate, a haven, and a tower, and devolves a flourishing kingdom on his son Gurguntius Barbirus. This prince, though mild and just, inherited his father's courage. He vanquished the Dane, whom Belinus had liberated on condition of becoming tributary, but who had violated his engagement. An event of still greater consequence, imputed to him, was the peopling of Ireland, which he is said to have effected by sending over some of his subjects with a colony from Spain, which he happened to find on board a fleet at the Orkneys, on his return from this successful war. They were led by Bartholinus, unjustly banished his country, as he alleged, and who now sought an asylum in the king's dominions.

Martia enacts laws. Morindus, &c.—Some useful laws are said to have been instituted in the reign of his son Guitheline, aided by the queen-mother Martia, whose wisdom is much extolled, and to whom in reality they have been ascribed. It is a little curious, and worthy of remark, that Milton, in relating this, is anxious to deprive her of such an honour, excepting in so far as she was guided by sage counsellors of the other sex, asserting, in his nervous but uncourtly style, that there can be "nothing more awry from the law of God and nature, than that a woman should give laws to men." During the reign of the third or fourth descendant of this legislatrix, as she may be called in spite of such authority, a king of the Morines, or Picards, is reported to have invaded Northumberland, but with no success, the British monarch Morindus, a man of uncommon strength and bravery, having overthrown his army,—a victory which he dishonoured by the inhuman slaughter of all the prisoners. This prince is said to have perished in a singular manner, being devoured by a monstrous creature which had arisen from the Irish sea, and infested the neighbouring coast, and which, confiding in his personal ability, he had ventured to encounter.

Generosity of Elidure, &c.—Gorbonian, the eldest of his five sons, is highly extolled for his piety, wisdom, and affectionate regard for the welfare of his subjects. He was succeeded by his brother Archigallo, not by any means equally praised. Being deposed from the government, the next brother, Elidure, of promising character, was called to the throne. The romantic behaviour of this prince, surnamed the pious, merits distinguished notice. After a conciliatory and equitable reign of five years, as he was one day hunting, he happened to meet his deposed brother in a very mean condition, immediately on returning from abroad, where he had long vainly solicited aid to effect his restoration, and now so much humbled as to be obliged to beg subsistence among any secret friends at home. Elidure affectionately embraces him, welcomes him to his native land, and immediately contrives means to prove the sincerity of his brotherly regard. Having concealed the wanderer in his own bed-chamber, he feigns himself so unwell as to require the assistance of his peers, in order to determine on a successor to the throne, in all likelihood soon to be vacant. These he admits to his counsel one by one, as if his weakness could not endure the fatigue of more at a time, and induces, each in his turn, to swear allegiance once more to Archigallo, whom, after reconciliation on all sides, he conducts to York and has immediately crowned. Such generosity was not unrewarded by the subse-

Civil history.

quent behaviour of the prince, so unexpectedly restored to empire. The heroic deed seems to have wrought his conversion, and promoted a worthy reign of ten years duration. On his death, Elidure reassumes the government, but soon finds occasion to put his virtue to the test,—his younger brethren, Vigenius and Peredure, not won by such excellence, rebelling against him, and that indeed with too much success. After defeating him, and making him prisoner in the Tower of Trinovant (London,) they divide his kingdom, Vigenius taking the south and Peredure the north. On the death of the former, the whole fell into the hands of Peredure, whose government, notwithstanding the means by which it was acquired, deserved commendation. He, too, dying, Elidure, after many years confinement, is again seated on the throne, which he continued to fill in tranquillity, and with exemplary mildness, till his decease.

Long series of uninteresting reigns.—To these five brethren, succeeded several of their sons in order; at last the son of Elidure reigns, and gives rise to a race which is prolonged for many generations, but with few, if any, remarkable peculiarities, till we arrive at Blegabedrus, who is reported to have excelled all before him in the art of music, " opportunely, says Milton, had he but left us one song of his twenty predecessors' doings." Then comes a series of nine kings, equally mute and insignificant, or equally unfortunate in want of historians, the last of them alone, Cliguellius, having an addition to his name of modest, wise, and good. Heli, son of this commendable personage, after reigning forty years, left three sons, Lud, Cassibelan, and Nennius. The first of these, a hardy soldier, and a noble feaster, conquered many islands of the sea, says one of the historians, and was buried in the city henceforth called after him Caerlud, or Lud's town, now London, by the gate still bearing his name, viz. Ludgate. The two sons of this prince, committed to the tuition of his brother Cassibelan, were so far favoured by him, as to have portions of territory consigned them, viz. London with Kent on Androgeus, and Cornwall on Tenuantius; Cassibelan himself, whose liberality and behaviour had won the affections of the people, retaining sovereign power till the arrival of the Romans in the island.

Probable origin and early history.—The only inference which it may be safe to deduce from the preceding relation, is, that long before the event now alluded to, this island had undergone a great variety of revolutions, and that its inhabitants were accustomed, on various accounts, to carry on an intercourse with several parts of the continent. It is the probable opinion of some authors, that it was originally peopled from that portion of Gaul which corresponds with the opposite shores of Flanders and France. Hence the term Gael or Guydel, as the Welsh denominate their Celtic predecessors in the country, by way of distinction from their own ancestors the Cumri, Cymri, or Cimbri, who acquired it either by conquest, or, which is more likely, after the departure of the former for Ireland, which seems to have been peopled by them, and from which a branch of the same stock latterly found their way into the Highlands of Scotland. To the Celtic, it is said, succeeded a Gothic race in England, a branch of the Scythians, which, in its career from Asia, drove the Cimbri from their abodes, and under the name of Belgæ obtained a settlement in that part of Gaul which is nearest Britain, long antecedent to the Christian era. The Phenicians are understood to have early carried on a commercial intercourse with this island, and to have called it Baratanac, whence Britain, perhaps, signifying *land of tin*, a metal in which some parts of it abounded.

Civil history.

Arrival of the Romans in 55, B. C.—Animated by his success in Gaul, and incited by its reputed wealth, as well as a desire to chastise its inhabitants for their repeated services to certain of his enemies, Julius Cæsar determined on visiting, and, if possible, subduing Britain, known to him already by frequent but not perfectly correct report. As he was little acquainted with the extent and nature of the country, and was more particularly uninformed as to the number and security of its harbours, he dispatched Volusenus, one of his officers, to view the coast, and in the meanwhile advances his troops to the place of embarkation. The Britons, soon apprised of his purpose, sent ambassadors with offers of obedience to the Romans, and hostages in pledge of their sincerity. These were civilly received, but did not accomplish the object of their mission, which was to prevent the meditated invasion. Volusenus having now returned, the general embarked his troops, and speedily got in sight of the British coast, probably near the cliffs of Dover, on which the islanders had assembled themselves in great force. Shortly afterwards he landed, as is imagined, near Deal, but not without a resistance in which he could easily discern their valorous and obstinate disposition. His troops, for some time almost panic struck, and repeatedly thrown into disorder, gradually, but with difficulty, obtained some advantage, on which they so far improved as at last to put the Britons to rout, though they were unable, from want of horse, to pursue them. The Britons, thus worsted, send ambassadors to sue for peace, which is granted on certain conditions, and the delivery of hostages. But a violent storm which soon afterwards came on, having dispersed or injured the greater part of the Roman fleet, they were induced, by the hope it afforded of expelling or destroying their invaders, to recommence their hostilities. They were again unsuccessful, notwithstanding a mode and a spirit of fighting which threatened the extermination of the enemy. Another proposal for peace was scarcely less necessary for Cæsar than for those who made it. He insisted only on doubling the number of hostages; and finding the season advanced so far as to render farther stay in the island injudicious and unsafe, immediately afterwards set sail for Gaul.

Cæsar's second visit.—Having prepared a larger and better-fitted army, Cæsar returned in the following summer; and landing at a place formerly marked by him, immediately after fortifying a camp, according to the Roman custom, proceeded with part of his troops in search of the Britons, who, intimidated at the vast display of force brought against them, had hitherto given no opposition, but waited in anxiety for a suitable opportunity to attack with advantage, or resist with effect. They were united under Cassibelan, king of the Trinobantes, who had previously carried on almost perpetual wars with his neighbours, but whom they found it convenient to appoint commander-in-chief. After various encounters, in which the Romans suffered severe losses, and had reason to put in full force their military virtues, these brave islanders were completely defeated. Farther resistance was attempted, but proved in vain. In the issue, Cassibelan solicited peace, which Cæsar more readily granted, as it was again necessary for him to retire to the continent.

Such is the substance of this able general's own statement of his expeditions into Britain; in considering which with attention, and every allowance for both his modesty and his virtual self-commendation, more especially when compared with the reports of other writers, and paying due regard also to the little immediate fruits of any claimed victory, it seems fair to conclude that he was very far from being fortunate in the enterprise. To his spirited and intelligent Commentary, nevertheless, posterity is indebted for something like authentic information respecting the early, though, probably, not the original inhabitants of this island.

Milton's summary description of the inhabitants.—The sentence, in which our illustrious poet has summed up the particulars of his intelligence, aided by remarks from other authors, is an instance of condensation of matter perhaps unexampled in any writer but himself. With very little modification, it is here inserted, in place of any more lengthened, but very probably less satisfactory observations on the various subjects to which it relates. "At Cæsar's coming hither, such likeliest were the Britons, as the writers of those times, and their own actions represent them,—in courage and warlike readiness, to take advantage by ambush or sudden onset, not inferior to the Romans, nor Cassibelan to Cæsar,—in weapons, arms, and the skill of encamping, embattling, fortifying, over-matched; their weapons were a short spear and a light target, a sword also by their side; their fight, sometimes in chariots, fanged at the axle with iron-scythes; their bodies most part naked, only painted with woad in sundry figures, to seem terrible, as they thought; but if pursued by enemies, not nice of their painting, to run into bogs up to the neck, and there to stay many days, holding a certain morsel in their mouths, no bigger than a bean, to suffice hunger: Their towns and strongholds were spaces of ground fenced about with a ditch, and great trees felled overthwart each other; their buildings within were thatched-houses for themselves and their cattle: In peace, the upland inhabitants, besides hunting, tended their flocks and herds, but with little skill of country affairs; the making of cheese they commonly knew not; wool or flax they spun not; gardening and planting many of them knew not; clothing they had none, but what the skins of beasts afforded them, and that not always; yet gallantry they had, painting their own skins with several portraitures of beast, bird, or flower: Towards the sea-side they tilled the ground, and lived much after the manner of the Gauls their neighbours, or first planters; their money was brazen pieces or iron rings; their best merchandize tin, the rest trifles of glass, ivory, or such like, yet gems and pearls they had in some rivers; their ships of light timber, wickered with ozier between, and covered over with leather, served not therefore to transport them far, and their commodities were fetched away by foreign merchants; their dealing, plain and simple, without fraud; their civil government under many princes and states, not confederate or consulting in common, but mistrustful, and oftimes warring one with the other: their religion was governed by a sort of priests or magicians, called Druids, from the Greek name of an oak, which tree they had in great reverence, and the misletoe especially growing thereon. Pliny writes them skilled in magic, no less than those of Persia; by their abstaining from a hen, a hare, and a goose, from fish also, saith Dion, and their opinion of the souls passing after death into other bodies, they may be thought to have studied Pythagoras; yet philosophers I cannot call them, reported men, factious and ambitious, contending sometimes about the archpriesthood, not without civil war and slaughter; nor restrained they the people under them from a lewd, adulterous, and incestuous life, ten or twelve men, absurdly against nature, possessing one woman as their common wife, though of nearest kin, mother, daughter, or sister; progenitors not to be gloried in. But the gospel, not long after preached here, abolished such impurities; and of the Romans, we have cause not to say much worse than that they beat us into some civility, likely else to have continued longer in a barbarous and savage manner of life."

Britain neglected by the Romans.—The Britons lived unmolested by the Romans for near a century after the invasion of Julius Cesar, various causes preventing the first three emperors, his successors, from carrying their arms into the island. During the greater part of this time they paid no tribute, and only on particular occasions sent gifts to the capitol. Their country, however, became pretty well known throughout the empire, from the reports of travellers and merchants, who continued to visit it. Of their internal affairs, nothing very memorable is related. Tenantius the younger son of Lud, succeeded Cassibelan, and is noted as a just and warlike prince. After him came his son Kymbeline, or Cunobeline, said to have been brought up in the court of Augustus, and to have continued on the most friendly terms with that monarch to the end. Then followed Adminius, and his brothers Togodumnus and Caractacus.

Visited by Claudius.—It was in the joint sovereignty of these two last princes, that the emperor Claudius, desirous of doing something that might merit the honours of a triumph, and signalize his reign, resolved on the complete conquest of the island, to which he was apparently farther induced by the treacherous solicitations of Bericus, a Briton, but, as is imagined, banished his country for some seditious purposes. Claudius first sent over Plautius, one of his generals, by whom the two princes were separately defeated with great loss. The emperor afterwards arriving, obtained another victory, subdued some of the states, and, contrary to Roman economy,

Civil history.

which allowed the title to be taken only once in the same war, was several times saluted *Imperator*. But his moderation in a more important matter was displayed towards the Britons, by whom he was venerated, in consequence, with religious honours. Their excessive gratitude, nevertheless, was not extended to the Romans in general, with whom, on the speedy departure of Claudius, they continued to carry on a desultory and ruinous war, in which Vespasian and his son Titus, both of them afterwards made emperors, greatly signalized themselves.

Plautius, who had been left commander-in-chief of the army, in the absence of the emperor, after various successes, and subduing a great part of the island, returned to Rome, where he had the honour of an ovation decreed him. Ostorius Scapula, sent over in his place, met with many difficulties, but by prudence, spirit, and contriving to gain over some of the native princes to his cause, gradually extended his power; and at last encountering the main body of the Britons, under their noble and valiant leader Caractacus, obtained a decisive victory. That prince himself was shortly afterwards delivered up into his hands by the queen of some of the northern states, to whom he had fled for protection, but whom dread of incurring the Roman vengeance prompted to such a violation of fidelity.

Magnanimity of Caractacus.—The long and able resistance of Caractacus was matter of astonishment and indignation to the Romans. His capture afforded no less satisfaction. The Emperor, accordingly, willing to gratify the malignant passions of the people, and desirous himself of seeing a man whom bravery and skill, though not fortune, rendered so formidable an opponent, ordered him and his family, who were also taken captive, to be sent to Rome. A day was then appointed for exultation, when the people assembled, and the Emperor, with Agrippina his Queen, sat enthroned, to enjoy the triumph of his slavery.

It was on this trying occasion that the manly Briton, having, with undaunted countenance, followed the sad pageantry of his household, his brothers, his daughters, and his wife, all in chains, stood before the imperial tribunal, and made the following short but animated speech, as related by Tacitus: "If my moderation in prosperity had equalled my rank and fortune, I should have come to this city as a friend and not as a captive; nor would you have disdained to accept the offered alliance of a man, sprung from such illustrious ancestors, and acknowledged chief of so many nations. My present condition is no less dishonourable to me, than it seems gratifying to you. I once had horses, subjects, arms, riches,—what wonder is it that I should unwillingly relinquish them? Think not, because you wish for universal empire, that, therefore, all mankind will readily submit to slavery. Had I been earlier betrayed, neither my calamity nor your glory would have been so illustrious. Your ungenerous treatment of me may, indeed, be forgotten; but if you preserve me uninjured, I shall certainly become an eternal monument of your clemency." The emperor, moved at so spirited an address, immediately granted him pardon, and decreed liberty to all the prisoners.

The natives still resist.—The Britons, not yet subdued, had in the meantime taken advantage of some negligence on the part of Ostorius, who now conducted himself as if he had rather to reap the fruits of victory, than to render it availing. A bold attack on some of his troops roused him to a sense of danger, and renewed his exertions; in several skirmishes which followed, he recovered the ground which he had lost; but impatience and vexation at such continued, and, in reality, now no longer honourable warfare, at last ended his days. His immediate successors disappointed expectation. Paulinus, a prudent and experienced officer, appointed by Nero, was more successful. He effected the conquest of Mona, understood to be the island of Anglesey, and esteemed the chief seat of druidical mysteries and veneration. But, while engaged in this undertaking, a general insurrection among the Britons, thinking to profit by his absence, and stimulated by intolerable injuries, forced him to attend to the safety of the Roman colonies, now threatened with their vengeance.

Civil history.

Are totally defeated.—About this period Boadicea, queen of the Iceni, (the inhabitants of Suffolk and Norfolk,) in whom the most indecent and barbarous usage had stirred up a spirit of vindictive bravery uncommon in her sex, headed her tumultuous countrymen, to the number it is said of more than 200,000. They attacked with effect several settlements of the Romans; London itself, which Paulinus, though anxious to succour, had found it requisite to abandon, fell into their hands, and was soon reduced to ashes; no less than 70,000 persons, inhabitants of it and some adjoining towns, being, at the same time, put to the sword. So signal a display of resentment seemed to imply the absence of both hope and desire of ever coming to any peaceable understanding with the Romans. It was no less signally revenged by a total defeat of the Britons, about 80,000 of them being slain on the field, and Boadicea afterwards poisoning herself from grief and shame at the loss. To add to their miseries, a famine, the natural consequence of their present unsettled habits, swept off great multitudes. Paulinus used his victory with little moderation; and being thought, by his rigorous measures, to have irritated the Britons to excess, was speedily recalled. The command was now given to Cerealis, who maintained the authority of the Roman arms. To him succeeded Frontinus, equally fortunate in preserving and extending his power.

Entire subjugation by Agricola.—The complete reduction of the country, notwithstanding the perpetual and vigorous exertions of the Romans, was not accomplished till the reign of Titus, under the government of one of their most illustrious men, Julius Agricola, whom Vespasian had sent over in the end of his life. His first campaign gave promise of his glory, both as a soldier and a promoter of the arts of peace. The victories which he gained over the Britons were made conducive to their improvement; and in a few years the whole of England, submitting to the power of his arms and his judicious policy, assumed the name and appearance of a Roman province. Nor was he inattentive to its future security. The establishment of walls, and a chain of garrisons, between the friths of Clyde and Forth, undertaken by his orders, was intended to guard against invasion from the Caledonians, who had experienced indeed something of the terror of his name, but by no means generally acknowledged his authority.

Romans defend their conquests.—Nothing very important occurred after this time till the reign of Adrian. This emperor, during a short visit to the island, built a rampart between the Solway frith and the river Tyne, to protect what was Roman from the ravages of the northern barbarians. But this wretched substitute for patriotic hardihood was only of use when defended by disciplined soldiers. It was repeatedly transgressed, and in the reign of Antoninus Pius, considerably injured, which induced that monarch to send over one of his officers for the purpose of chastising the invaders, and confining them within narrower limits. A renewal of their ravages excited the still more energetic resentment of the emperor Severus, who extended the province far into the north of Scotland; but perceiving at last the extreme insignificance of his conquests, he finished his labours by building a wall very nearly in the same situation as Adrian's rampart. This monarch died at York in the beginning of the third century after Christ.

The island improves, is again divided, &c.—The spirit of the Britons was now completely quiescent under the Roman yoke, and readily admitted the various refinements which it was the policy of the masters of the world to promote among their subjects. For some years, accordingly, the dull uniformity of events in the island was but occasionally broken by dissentions among the Romans themselves, or the paltry visitation of some northern stragglers, who contrived to evade the vigilance or elude the pursuit of the soldiery. Good historians were become scarce; those who were in any measure respectable, found objects of more consequence to engage them than the concerns of a distant and little prized province. The few events worthy of being recorded may be therefore briefly stated. The emperor Probus permitted the cultivation of the vine in Britain about A. D. 276. In the reign of Dioclesian, a persecution of the Christian religion, which had been early introduced into the island, and extended rapidly, took place. Several persons of consequence were put to death for their faith, especially at Litchfield, "for which cause," says an old writer, "that city doth bear, for their seal of arms, a field charged with many martyrs." Constantius Chlorus, who succeeded to the western empire, was more mercifully disposed, and is said, indeed, to have become a convert during his former command in the island, through the instrumentality of his wife, Helena, daughter of a British prince, and mother, as some think, of Constantine the Great. Constantius died at York in 307, immediately on commencing an expedition against the northern people, but not before he had the satisfaction of seeing his son, now named, and appointing him his successor to the throne. During Constantine's reign the Britons enjoyed profound peace, and were at liberty openly to profess Christianity. Having divided the empire into four governments, this island became subject to the præfect of Gaul, and was administered by a *vicarius* or deputy under him. Hitherto, at least for some time, it had been subdivided into two provinces, but now, by Constantine's direction, into three, denominated,—*Britannia Prima*, which comprehended all the country south of the Thames, having London for its capital, and so called from its having been first conquered; *Britannia Secunda*, containing all the country west of the Severn to the Irish sea, now called Wales, with Caerleon, or Chester, for its capital; and *Maxima Cæsariensis*, comprehending all the remainder, lying northward of the Thames and eastward of the Severn, having Eboracum or York for its capital.

Troubled by the Scots, &c.—The Britons suffered much in the reign of Constantius, one of the sons of Constantine, from the cruelties and exactions of Paulus, an officer sent over by him, and suffered, in spite of various complaints, to continue his iniquitous proceedings. Their country was invaded in the time of Julian by the Picts and Scots, now become extremely troublesome; and still more so in the reign of Valentinian I. several of whose officers were worsted in attempting to keep them in check. Theodosius the elder, at last appointed by him to this undertaking, was more fortunate in beating them back into their own territories. This general repaired London, at this period greatly declined from its former splendour. He farther extended the Roman power in the island, and built various fortresses for the defence of the inhabitants. Maximus, in the reign of the second Valentinian, was no less successful against the Scots, many of whom he forced to fly into Ireland and the adjacent isles. But they returned in a subsequent reign, and, in conjunction with the Picts, pursued their wonted ravages on the northern borders.

The Romans withdraw, A. D. 426–448.—The period was now hastening, in which the accumulated distresses of the empire precluded the possibility of affording adequate support to this remote province. Repeated solicitations, in which the Britons displayed little of their former spirit, were ultimately met with a reply which absolved them of their allegiance, and left them without hope of farther assistance. The last service which the Romans performed was the rebuilding of the wall of Severus, when they took their departure, after a residence and dominion of about four centuries duration. This took place in the reign of Honorius.

The Saxons invited over, A. D. 450.—It does not exactly appear what kind of government was left in the island; but it is certain, that, in a short time, the different and frequently-contending parties and states found it necessary to acquiesce in the ascendancy of a prince named Vortigern, or Gwrtheyrn, king of Devon and Cornwall, by whose advice, after some unsuccessful endeavours to repel their northern invaders, the Britons determined on calling in the Saxons to their aid. Some of these people had already landed in the south of England, which they were in the habit of visiting during their piratical expeditions. Their countrymen at home readily acceded to a request so flattering to their country and so promising to their expectations. Hengist and Horsa, sons of Witigisil, their general, were appointed to the command of about sixteen hundred men destined to this service. They were welcomed with extraordinary joy, and put in possession of the isle of Thanet, which, after some altercations among the states, had been selected as the fittest place for their landing, and their residence when about to return to their own country. Their first engagement with the Picts and Scots, who had by this time advanced as far south as Stamford in Lincolnshire, confirmed the opinion and hopes which were entertained of them. These confident invaders, astonished at their appearance and military skill, made but feeble resistance, and speedily fled from the field; nor was any subsequent attempt on their part more fortunate. They therefore gradually abandoned their conquests, and finally retired to their own country.

The Saxons contrive to remain.—A discovery was now made of the weakness of the Britons, and at the same time the comparative fertility and agreeableness of the island, of which their new associates were not tardy in availing themselves. Hengist, the leader of the Saxons, discerning his feeble character, contrived to engage the attention of the British prince, whilst some schemes for acquiring power were carried on. With this view he introduced his daughter to that vicious man, but, with affected modesty, declined an offer of marriage, till won by the generosity of Vortigern, who, becoming indulgent from impatience, grants a portion of Kent to the Saxons, in addition to the isle of Thanet, now represented as too small for their augmented numbers. This was followed by permission to bring over still more of his countrymen, under his son and nephew. It was suggested, that if they were allowed to settle towards the north of the island, they would operate as a continual check on their troublesome neighbours. Northumberland was accordingly assigned for their residence. But the consequences of such imprudent policy were soon manifested. Causes of quarrel arose between the Britons and their artful visitors, who fully developed their designs by actually forming alliance with the very people whom they had engaged to repel. This odious treachery excited the indignation of the Britons. A rebellion against Vortigern, whose imprudence and vices had occasioned general dislike, ended in his deposition. The people now put themselves under the command of Vortimer, his son, and fought many battles with the Saxons. In one of these Horsa was slain; so that Hengist was left sole leader of his countrymen. Reinforcements from Germany enabled him to prosecute his object with vigour. He accordingly spread the terror of his name throughout the island, sparing neither age nor sex, wherever any resistance was made to his victorious army. Thousands were butchered, and many more, dreading a similar fate, fled over to the continent, where they were humanely received, and at last settled in a province, which, from them, has ever since borne the name of Brittany.

They are ably opposed.—Hengist had now assumed the title of king of Kent, but was far from having attained the height of his ambition. New difficulties presented themselves. Ambrosius, a noble Briton, but of Roman descent, having been chosen leader of his countrymen, either on the death of Vortimer, or in preference to him, in some degree revived their courage. This enterprising man not only arrested the progress of their enemies, but also greatly allayed their mutual animosities, which were perhaps fully more injurious. It was in the army, under this chief, that Arthur, afterwards so illustrious, first appeared. The unexpected opposition which he thus encountered, obliged Hengist to call over more of the Saxons to his assistance. These, under Ella, landed at Whittering in Sussex. The war was resumed, after some respite, equally necessary for both parties. Ambrosius gained a signal victory over that general and his two sons, which necessitated the Saxons to retire to their strongholds, till supplies of troops came from Germany. Hengist himself did not live to finish the war, but died in 488, after residing in Britain thirty-nine years. His successor in the kingdom of Kent did not inherit his father's talents, and preferred the pleasures of peace to the fatigues of war. This enabled Ambrosius to improve his victory by the capture of London, Winchester, and Lincoln, which had formerly been seized by the Saxons.

Death of Arthur in 542.—A truce followed for about three years, in which time Arthur, who had greatly signalized himself, made a voyage to Jerusalem. On his return he found as much occasion as ever for his exertions. Successive reinforcements of Saxons, induced by the reported prosperity of their countrymen, had now arrived in the island, and aiding one another, gave great vexation to the Britons. In addition to the original kingdom of Kent, two separate estates were established, that of Ella in South Saxony or Sussex, comprehending Surrey, Sussex, and the New Forrest, and extending to the frontiers of Kent; and that of Cerdic in West Saxony or Wessex, including the counties of Hants, Dorset, Wilts, Berks, and the isle of Wight. It was chiefly in opposing this last named prince and his son Kenric, both of whom had landed in 495, that Arthur obtained his fame. He is reported to have vanquished the Saxons in twelve battles. But his personal valour and military talents were not alone sufficient to retrieve the declining fortunes of the Britons. His last days were imbittered by domestic trials, and he had the misfortune to be mortally wounded in a battle between him and his own nephew Modred, in the 90th year of his age, without perceiving that his heroic deeds could avail to prevent as they had retarded the subjugation of his country.

Complete establishment of the Saxons, 586.—After the death of this prince, the affairs of the Britons went speedily to ruin. No man of equal abilities arose to guide them by his counsel, or lead them to victory. A few attempts to resist their oppressors failed in their object; and more foreigners continuing to arrive at various times to share in the spoil of their country, completed their destruction. Many of those who survived such repeated defeats and the cruelty of the Saxons, took refuge in Wales, where the kindness of nature provided a defence in almost inaccessible mountains and rocks. Others, nearer the eastern side of the island, fled to that part of the continent where their countrymen were already settled. A few submitted to the power of the conquerors, accepting of life on low and unworthy conditions. Thus, after an obstinate and sanguinary contest for 130 years, the whole of England was re-

Civil history.

duced under the government of the Saxons. The people so denominated were, properly speaking, of three tribes, to whom the distinct names of Saxons, Jutes, and Angles have been given. They appear to have come originally from the same region, viz. the southern part of the peninsula of Jutland, and some adjacent isles, and, from their similarity in several respects, may be considered as the offspring of one stock. The first of these names has been retained in the history of this country, as generally applicable to its conquerors, but the island itself derived its most usual title from the last of them. Accustomed, from an early period, to subsist by piracy, these people had little cultivated any of the arts which contribute so much to human happiness. They were brave and hardy, indeed, but extremely rude in manners, addicted to gross vices, and scarcely less odious superstition, and shewed an utter dislike to that system of religious and moral truth which had already made considerable progress in the land of their conquests, but which they persecuted with the bitterest and most unrelenting rage.

Summary account of the Saxon States.—The government established by the Saxons in Britain, has commonly been denominated a Heptarchy, as supposed to comprehend the seven kingdoms of Kent, Sussex, Wessex, East-Anglia, Essex, Northumberland, and Mercia. But the title of Octarchy is more appropriate, Northumberland being divided into Bernicia and Deira.

The kingdom of Kent was established by Hengist. His son and successor, Escus, but not the inheritor of his abilities, scarcely retained the dominions bequeathed to him. In the reign of Octa, who then followed, Essex and Middlesex were dismembered from Kent, by the new establishment of the East Saxons under Ella, on whom Escus had conferred the command of the Saxon army. After this prince reigned Hermenric, the father and colleague of Ethelbert, one of the most illustrious monarchs in the history of these times. His first attempt to recover the lost dignity of his family was unsuccessful. He was worsted by Ceaulin, king of Wessex, whose ambitious designs, and oppressive conduct, at last produced a league among the other states. Ethelbert, chosen their general, defeated him in turn, and speedily acquired ascendancy in the island, all the princes, with the exception of the Northumbrian, chusing to submit to his power rather than run the risk of contention. The haughtiness and arbitrary principles of this monarch were a little moderated by his apprehension of exciting such a coalition against him as had ruined Ceaulin. He prudently, therefore, relinquished some measures which he perceived to occasion dislike, and so preserved himself from the like fate. The most remarkable event in this prince's reign was the introduction of the Christian religion, originally by means of Bertha his wife, daughter of Caribert, king of Paris, whose influence over her husband so far prevailed over his prejudices, as to give encouragement to Pope Gregory the Great to send over Augustine as a missionary among the Saxons. This monk arrived in England in 597, and immediately commenced his spiritual labours. Ethelbert himself became a convert, and his example was soon followed by his subjects. This prince died in 616. None of his successors was either possessed of his talents, or enjoyed his good fortune. The kingdom of Kent soon languished, and was merged in the time of Baldred, its last prince, in the dominion of one monarch over the Saxon states.

The kingdom of Northumberland was established by Ida in 547. On the death of this prince in 559, it was divided into two parts, already mentioned, Bernicia and Deira. His successors were no way eminent till 590, when Adelfrid, prince of the former, distinguished himself by his military talents and his re-combining the two kingdoms, to the prejudice of Edwin, rightful heir of the latter, whose misfortunes, wanderings, prosperity, and death, have altogether more the interest of fiction than the evidence of truth. His reign in Northumberland was marked by the introduction of Christianity, the rigorous administration of justice, and a reputation for activity and power which secured the highest respect among the other states. Envy of his greatness prompted the Mercians and Welsh to form a league against him. This led to a battle, in which, from excessive grief or rage at the death of his son, who was slain at his feet, he plunged amongst the ranks of his enemies, and fell in the 48th year of his age. The affairs of his kingdom went immediately to ruin, the conquerors behaving with extreme cruelty, and the people themselves being divided as to the succession. After various calamities, and an interregnum, Oswald, son of Adelfrid, ascended the throne of both kingdoms. He is represented as a religious and able prince, but his short reign did little service to his country. He perished in battle with Penda, king of the Mercians, the enemy of Edwin, and was succeeded in Bernicia by his brother Oswy, and in Deira by Oswin, son of Osric, formerly king of the same country. The former having murdered Oswin, reunited the two kingdoms in his own person, but his affection induced him to divide it with his natural son Alfred, to whom he gave Deira. Egfred his son, by a daughter of Edwin, succeeded him in Bernicia, and, by a revolt of the people, acquired also that kingdom, Alfred being obliged for a time to retire into Ireland. This prince dying without issue, Alfred was recalled, and put in possession of both kingdoms, which he had extreme difficulty to preserve against the attacks of his neighbours. The subsequent history of Northumberland presents a series of discontents, anarchy, and calamities, which fitted it for complete subjection to a foreign yoke on the dissolution of the Octarchy.

The kingdom of East-Anglia, containing the counties of Norfolk, Suffolk, and Cambridge, was founded in 575. Its history is almost totally uninteresting. Earpwold, the fourth king, embraced Christianity, and afterwards abandoned it at the suggestion of his wife. Sigebert, his successor, was educated in France, where he acquired a more rooted attachment to that religion. Ethelbert, the last prince, was murdered by Offa king of Mercia.

The kingdom of Mercia, comprehending the middle counties of England, was established about 590, by Crida, to whom, after an interval filled up by the conquest of Ethelbert king of Kent, succeeded his son Wibba. Of Penda, the next but one in succession, mention has already been made in the history of Northumberland, to which he proved so vexatious an opponent. He was slain in battle in the 80th year of his age, after a restless and sanguinary reign. Wulfer his son, like himself, was a pagan at ascending the throne, but afterwards embraced Christianity, in which faith his children were educated. The greatest princes of this kingdom were Ethelbald and Offa, in the beginning and middle of the 8th century. Offa, particularly, is distinguished by military spirit, successful enterprize against the kings of Kent and Wessex, and his having acquired the friendship of Charlemagne. His merit is eclipsed by great hypocrisy, and the treacherous murder of Ethelbert king of East Anglia. Wiglaff, the last king, had, like all the other Saxon princes his contemporaries, to submit to the superior power of Egbert king of Wessex.

Kingdom of Essex.—The history of this state, founded in 527, is extremely imperfect, and void of any subject deserving much notice. Sabert, who ascended the throne in 604, embraced the Christian religion at the solicitation of his uncle Ethelbert king of Kent. His three sons, who jointly reigned after him, forsook his faith, and were all cut off in battle with the kings of Wessex. Sigebert, denominated *the good*, who succeeded his father of the same name, but styled *the little* from his smallness of stature, restored Christianity in his dominions. Swithred was the last king.

The kingdom of Sussex, founded by Ella in 477, makes as poor a figure as the preceding. Cissa, son of Ella, had a reign of seventy-six years duration, the only peculiarity for which he is remarkable. Leaving no issue, Ceaulin king of Wessex seized the kingdom. This occasioned a league against him, by which he was overcome; but he was not prevented from leaving it to his nephew and successor Ceolric. It was the misfortune of this small state to be almost constantly exposed to the dominion of some powerful neighbour, till its union with Wessex, by which all the rest were finally vanquished.

Wessex was founded by Cerdic in 519, but not without the greatest opposition on the part of the former inhabitants, a circumstance which might both have required and kept up that high degree of military spirit displayed by the Saxons of this state. Kenric, the son and successor of Cerdic, defeated the Britons in 552. After him reigned Ceaulin, who extended his territories by wars with that unfortunate people, but who, by provoking some of the Saxons of thea djoining states, and incurring the dislike of his own subjects, was expelled from his throne, and died in exile. Kyneglis, who mounted the throne in 611, embraced Christianity. His successor, Kenwalch, was victorious over the Britons. He left his crown to his widow Sexburga, a woman of great courage, by whom it was kept till her death. After some princes of no note came Ceodwalla, celebrated for his abilities, and then Ina, one of the most illustrious princes during the Saxon dominion. He was successful over the Britons, whom he afterwards treated with exemplary mildness; he compiled a body of laws, and published them throughout his territories; he built and repaired several places of worship; and, after a prosperous reign of thirty-seven years, he made a pilgrimage to Rome, and, on his return, devoted the remainder of his days to pious seclusion from the world. His cousin, Adelard, succeeded him; then, after two unimportant princes, followed Kenulph, who gained several battles against the Britons. In the reign of Brithric his son, from 784 to 799, the Danes, now formidable at sea, are said to have made their first appearance in the kingdom of Wessex. This prince was poisoned by his wife, which occasioned the West Saxons to enact a law prohibiting the wives of their future sovereigns from taking the title of queen, or sitting on the throne of their husbands. It was during this reign that Egbert, grand-nephew of Ina, and afterwards so great a personage, began to attract the regard of this people. He had too much good sense not to perceive the danger of popularity under a jealous monarch, and accordingly withdrew in time to the court of Charlemagne, where his natural talents found a suitable soil for their growth and perfection, and where, it is no less probable, his political views were pointed to the ostensible advantages of an extensive territory under the guidance of one skilful head. Opportunities were afterwards afforded him of realizing some of them in his own land.

Egbert crowned king of England, A. D. 827.—The death of Brithric occasioning a vacancy in the throne, Egbert was recalled from France in order to fill it. At this period he was the only surviving descendant of those Saxon warriors who had conquered Britain, which, together with his great reputation, may have conduced to such a preference. His first measures were moderate and conciliatory, calculated rather to heal the differences which had arisen among the various states, than to excite alarm as to his intentions of profiting by them. He was accordingly often chosen mediator among the princes, which necessarily gave him influence, and furnished information suitable to his views. A politic attack on the Britons in Cornwall seemed still more decidedly to indicate his patriotic disposition; but, while engaged in this enterprize, his own dominions were invaded by the king of Mercia, a measure which plainly justified and required the most resolute opposition on his part, and afforded a pretext for a very different line of conduct from what he had hitherto pursued. He obtained a victory over that prince at Wilton, and, during the pursuit of the enemy into their own country, dispatched some of his forces, under his son Ethelwolf, into Kent, where the people had shewn a dissatisfaction with the reigning monarch, which promised him a fair opportunity of acquiring the sovereignty of that nation. His hopes were realized in both directions. The Mercians were entirely subdued, and Kent acknowledged his power. The other states were successively obliged to fall into his hands, that of Northumberland being the last which submitted. A general council of the clergy and laity, assembled at Winchester, crowned him king of England, by which name the united kingdom was now called, nearly 400 years from the time when the Saxons first arrived in the island.

Arrival and progress of the Danes.—The ascendency of so able and enlightened a prince, by combining the energies of the separate states, doing away their dissentions, and directing their respective advantages to the improvement and happiness of the whole, promised a state of prosperous tranquillity to the island. But this was far from being enjoyed. The frequent arrival of the Danes, in great numbers, on various parts of the western coast, was a source of continual apprehension and general uneasiness. Egbert prepared to repel and chastise their temerity, but not with that promptness or efficiency which their magnitude and formidable appearance required. In his first battle with them, at Charmouth in Devonshire, in 833, accordingly, he had the misfortune to sustain great loss, though the invaders were ultimately obliged to take to their ships for safety. About two years afterwards he was more successful, obtaining a signal victory over them at Hengston-hill in Cornwall, which for a time freed his country from their assaults. Egbert did not long survive this event. He was succeeded by Ethelwolf, a prince of much less ability, and whose resistance to those invaders was far from being equally effectual. He obtained indeed one complete victory; but, as he speedily sunk into sloth and superstitious debasement, this occasioned only a temporary delay to their progress. The visits of these people became more frequent than ever, and excited universal alarm, no place being secure from their depredations, and scarcely any power able to repel them. Instead of exciting and guiding the energies of his subjects, Ethelwolf proceeded on a pilgrimage to Rome, taking with him his fourth and youngest son Alfred, on whom he had at least the merit of bestowing all commendable affection and care. On his return, about a year afterwards, he was surprised to find a conspiracy had been formed to expel him from the throne, in which his eldest legitimate son Ethelbald, on the death of Athelstan, natural son of Ethelwolf, and appointed by him king of Kent, took a principal share. In the issue, the kingdom was divided, the father accepting the eastern part, and the son being appointed to govern the western. The former survived this partition two years, and left his share of the dominion to Ethelbert, another of his sons, who, on the death of his brother, reunited the two kingdoms. This virtuous but weak prince had the folly to bribe the Danes to leave the country, which, as might have been expected, encouraged their visits. The short reign of his successor, Ethelred, the third son of Ethelwolf, was full of calamities, notwithstanding his own bravery, and the assistance he derived from his younger brother Alfred, on whom, at his death, occasioned by wounds received in battle against the Danes, he devolved a kingdom rent with civil discord by the secession of the Northumbrians, and exposed to the ravages of a fierce and overwhelming enemy.

Reign of Alfred, A.D. 871.—This heroic and magnanimous prince had scarcely ascended the throne, when the success of the Danes demanded his most strenuous exertions. In the first engagement with them he was worsted; but this did not repress his spirit, nor did he relinquish his opposition, till the defection of his soldiers, intimidated by frequent misfortune, which they thought a judgment of heaven against them, forced him at last to abandon his regal attire, assume the garb of a peasant, and for some time owe his preservation to the obscure insignificance of a herdsman's cottage. Here, it is related, he had to encounter the rebuffs of his hostess, who was ignorant of his dignity, but was nevertheless a good judge of domestic concerns. Being one day directed to attend to some cakes which were preparing at the fire, while other matters engaged her superior skill, the prince, musing on his altered state, and meditating the recovery of his country, neglected to turn them, which the old woman perceiving, smartly upbraided him, saying, "he was always very ready to eat her warm cakes, but seemed careless enough about toasting them." A ray of hope visited him in this lowly retreat. Some of his most faithful adherents gathered together under his advice, and planned the overthrow of their unsuspecting oppressors. One advantage conducted to another, till the Saxons, increasing in numbers, and resuming courage with success, found themselves able to risk a general engagement, which was decided in their favour, after immense slaughter of the Danes, the remainder of whom either submitted to his authority, or were suffered to depart from the kingdom. Alfred's subsequent reign was full of glory, and dispensed multiplied benefits on his country; so that altogether his history has exhausted the commendation of historians, and furnished a fruitful topic for poetic embellishment. He was succeeded by his son,

Edward the Elder, A.D. 901.—This was a valiant and active monarch; but the circumstances of his reign prevented the developement of some of those excellencies on which his father's reputation was founded. He had early to encounter a dispute with his cousin Ethelward, who claimed the crown, and who was for a little supported in his pretensions by the Danes, and afterwards by the Normans, with whom he had been assisted out of France; then he had a war with the Danes, especially those of Northumberland, on their own account; to which succeeded a quarrel with the Welsh. Having fortunately recovered from these and other difficulties, he began to display his qualifications as a legislator and peaceful monarch, when death interrupted the accomplishment of his designs, after a reign of twenty-four years. His natural son,

Athelstan, A. D. 925,—succeeded to the throne. In the reign of this prince, the Scots, under Constantine, assisted the Northumbrian Danes in their efforts to embroil the kingdom, and were punished by his making an inroad into their own country, which was only abandoned on their humble submission. The same northern prince, nevertheless, soon formed an alliance against him with some Danish pirates and Welsh chiefs, who were jealous of Athelstan's power. He overcame them in a great battle near Brunsbury in Northumberland, after which he possessed his crown in peace. In his time the Scriptures were translated into the Saxon tongue.

Edmund I. A. D. 940,—ascended the throne on the death of his brother. He was an able and excellent prince, but his short reign admitted not all the benefits which his subjects expected from his talents and virtue. He subdued a king of Cumberland who had sided with the Danes, and reserving merely the sovereignty, bestowed it on the king of Scotland, with a view of attaching him to his interest. This probably gave rise to the notion of the Scottish kings being vassals to the kings of England, which they were, indeed, as to Cumberland, but by no means for their own country. Edmund's reputation was not confined to his native land, but spread so much abroad that the king of Denmark, though solicited by his countrymen in England, did not think it safe to encounter his enmity by sending them reinforcements. The sons of Edmund being too young to govern, he was succeeded by his brother,

Edred, A. D. 946,—in whom devotional feelings, and complete subservience to certain ecclesiastics, especially the famous Dunstan, abbot of Glastonbury, were curiously combined with vigour of spirit and firmness of character. The former prevailed towards the close of his reign, and rendered it less enterprising than it might otherwise have been.

Edwy, A. D. 955,—who now ascended the throne, was son of Edmund, and nephew of the last monarch. Equally able with his uncle, he differed widely from him in his notions of the clergy, who had already crept into power. Dunstan, formerly entrusted with an influence and authority which appeared to admit no controul, was very unexpectedly ordered to account for some monies received during the preceding reign, and refusing compliance, was deprived of his offices, and banished the kingdom. Such a shock to popular feeling and spiritual pride, proved more injurious to Edwy himself than to the object of his dislike. Odo, archbishop of Canterbury, who espoused the cause of the monk, pronounced a divorce between Edwy and his wife Elgiva. That unfortunate beauty was destined to endure still greater proofs of the vindictive rage which animated the ecclesiastic,—being seized in the palace by a party of soldiers under Odo's directions, branded in the face with a hot iron, to designate her character as a strumpet and adultress, banished into Ireland, and, on her return, again seized and put to death in a painful and barbarous manner. In the mean time, a revolt against Edwy on the part of the people, instigated by the clergy, and latterly headed by Dunstan himself, who now found courage to visit England, became so general as to force him to accept of an associate in the government in the person of his brother, by whom he was soon afterwards succeeded in the possession of the entire kingdom.

Edgar, A. D. 959.—This prince owed his premature elevation to the influence of the ecclesiastics, whom he felt bound in gratitude, as well as by a sense of interest, to favour on all occasions. The consequence is obvious, in the reputation which he acquired with the chief historians of the period. Some portion of credit is, no doubt, due to the real excellencies of his character, which, without any monkish partiality, would have demanded commendation. Few English monarchs, in truth, have enjoyed more present satisfaction and greater posthumous fame, notwithstanding certain immoralities and a spirit of gallantry, which, in a monarch less devoutly disposed towards his advisers, would have called forth severe animadversions. He has been denominated *the Peaceable*, to denote the uniform tranquillity of his prosperous, and, on the whole, beneficial reign. The reputation of this prince attracted many foreigners to his court, by whom, it is said, the manners and simplicity of the natives were greatly corrupted. But complaints of this kind, originating generally in prejudice and mistaken views of the nature of society, must be listened to with extreme caution. England, during the time of this prince, was so much infested with wolves, that, after various measures for their extirpation proved ineffectual, Edgar commuted the tribute which had been imposed on the Welsh chiefs, into three hundred heads of these animals, to be presented annually. This excited such successful industry in hunting them, that in a little time not one of them was to be found in the country.

Edward the Martyr, A. D. 957,—ascended the throne on the death of his father; but his reign, which was of only four years duration, offers nothing remarkable to notice. His claims to the title of Martyr, generally attached to his name, are not well explained by historians, and are certainly very dubious. He died young, indeed, and by assassination, through the instigation of his step-mother Elfreda. The former circumstance may, perhaps, imply innocence, and the latter has been ascribed to his affectionate regard for Dunstan and the monks. But these together, one should think, scarcely could have procured for him a place in the Roman martyrology, merited anniversary commemoration on the day of his death, or effected any sort of miraculous power at his tomb.

Ethelred II. A. D. 978,—succeeded his brother. He was a weak, incompetent, and unfortunate prince. In the third year of his reign, the Danes landed in different parts of the island, and committed great ravages. They were little opposed by the inhabitants, whose multiplied dissensions, superstitious reliances, and distrust in the government, rendered them an easy prey. Ethelred, more than once, endeavoured to redeem his country from devastation, by the offer of a large sum of money. This was readily accepted; but had no effect in preventing a repetition of hostile visits, by which the Danes at last obtained a firm footing, and almost predominant influence in the kingdom. Their conquest would have probably been complete at this period, if they had not been called over to the continent by Richard duke of Normandy, to assist him against the king of France, by whom his dominions were threatened. A short respite from their oppressive conduct prepared the English for more poignant affliction at their return. Ethelred, unable to make head against them, yielded to pay them thirty thousand pounds, which was levied by a tax called Danegeld, that is, Danish money, or money for the Danes. This procured a temporary good understanding between the two people, which induced many of these foreigners to settle in the country and form alliances with the natives. The king himself was now at liberty, on the death of his queen, to ask a daughter of the duke of Normandy in marriage. The success of his suit seems to have inspired him with the hope of receiving assistance from that prince when necessary, and to have prompted him, accordingly, to the commission of an act, which justly excited the resentment of the Danish nation. This was a general massacre of that people resident in the island, undertaken by his orders, and executed everywhere on the same day, without respect to age, sex, or condition. Such inhuman policy was productive of still greater calamities. The king of Denmark, hearing of the fate of his countrymen, prepared a fleet for the invasion and conquest of England. He landed in Cornwall with a powerful army, and immediately marched to Exeter, which he reduced to ashes, putting all the inhabitants to the sword. This was merely a sample of his revenge. Many other towns shared the same fate, after an army sent to oppose him had been totally defeated. He passed the winter in Denmark, but returned in the following spring, to pursue a like course of sanguinary retribution. Treachery and famine completed the miseries of the English, who were glad to purchase a little relief at any price; and Ethelred himself was forced to take refuge in the court of his father-in-law.

Canute proclaimed king by the Danes.—He had not remained above six weeks in Normandy, when he heard of the death of Sweyn, king of Denmark, who thus acquired the sovereignty of England. Canute, son of that monarch, was proclaimed his successor in that kingdom by the Danes; but the English prelates and nobility, encouraging the hopes of better times under a native prince, whom misfortune might be supposed to have taught some profitable lessons, invited Ethelred to return. He eagerly embraced the opportunity; but soon manifested his incapacity to render it either honourable to himself or beneficial to his subjects. Avarice, cowardice, and indolence, prevailed over the dictates of experience. He witnessed the greatest part of his dominions in the hands, or subject to the ravages of his enemies, almost without an effort to resist them; he had the ingratitude to suspect his countrymen of an intention to deliver him up to the Danes, as the only means of obtaining peace; and the meanness to feign himself sick, in order to avoid leading his army to battle. He died at London, after an inglorious reign of thirty-seven years, leaving a divided and almost desolate kingdom to his son.

Edmund, A.D. 1016.—This prince, from the robustness of his form, the hardiness of his constitution, and his valiant opposition to the enemy, was surnamed *Ironside.* He had courage and talent proportioned to his bodily qualifications. But all of these were inadequate to recover his country from the calamities with which it was oppressed. He had to contend with a rival no less distinguished by character, though of a weakly habit of body, and possessed of greater means than himself. The struggle between him and Canute was carried on with the greatest bravery and spirit, and with various success for a short time. These princes esteemed each other, though their contrariety of interest involved them in the fiercest hostility,—no less than five pitched battles having been fought by them in one year. Through the treachery of Edric, an English nobleman, who had given repeated proofs of villainy, Edmund at last sustained a severe defeat at Ashdon in Essex, which threatened the entire ruin of his hopes. But the affection and reliance of his subjects made still another effort to retrieve them. He collected a new army, with which he offered battle at Deerhurst in Gloucestershire. Canute, equally active, prepared to meet him. The two kings, sensible of the importance, and, probably, decisive nature of the issue, stood long in sight of each other, without giving the signal for engagement, when Edmund, in order to prevent the effusion of blood, proposed a personal combat with his adversary. This was prudently declined on Canute's part, but was returned by an offer to settle the dispute by the amicable decision of their principal officers. A division of the kingdom was the consequence, much to the displeasure of Edmund, though his regard to principle, and apprehension of a dispute with his nobles, who were extremely solicitous to put an end to the miseries of war, secured his observance of its conditions. He did not survive this painful event above a month, having been murdered by his chamberlains, at the instigation of the execrable Edric, who imagined, but very erroneously, he should thereby ingratiate himself with the Danish monarch.

Canute, A. D. 1017,—now obtained entire possession of the kingdom, the two sons of Edmund, who were minors, being unable to maintain their claims to their father's dominions, and their two uncles, the brothers of that prince, at this time residing in Normandy. After firmly establishing himself on the throne, which he could not do without some severities, he began to display a moderation and humanity of disposition, much more reconcileable with his character, and which, with his prudence and good sense, have procured him an enviable distinction in history. He sent many of his followers out of the country, in order that they might not give offence to the natives; administered justice impartially to both people; and, with a view of confirming the good understanding between them, married Emma, sister of Richard duke of Normandy, and widow of Ethelred, to whom the English looked up as the guardian and protectress of their interests.

After thus settling his authority, Canute undertook a voyage to Denmark, where his presence was requisite to resist an invasion made by the king of Sweden. In this expedition he was assisted by several English noblemen, especially Godwin, whose brave and successful, but by no means warranted attack on the enemy, procured the commendation of Canute, and the title of Earl of Kent as his reward. In another expedition to the north, Canute annexed Norway to his dominions. The latter years of his reign were pacific, and proved salutary to England. His only military enterprise was against Malcolm king of Scotland, who was obliged to acknowledge vassalage for Cumberland, and his liability to the tax of Danegelt for that province. Canute became devout towards the close of his life, built churches, endowed monasteries, and made a pilgrimage to Rome, where he obtained several privileges for his English subjects. He left three sons, Sweyn and Harold, by his first wife, Alfwen, daughter of the Earl of Hampshire; and Hardicanute by Emma.

Harold, surnamed Harefoot, A. D. 1035,—succeeded to the crown of England, by the will of Canute, though in violation of the marriage treaty with his second wife, by which that kingdom was settled on her eventual offspring. Hardicanute, already in possession of Denmark, conceived himself wronged by this appointment, and being favoured by the English, slowly prepared to assert his pretensions. Harold, on the other hand, had the suffrages of the Danes, and was, besides, on the spot to secure the vacant throne. A compromise between them left London and the provinces north of the Thames in the possession of Harold, while the southern part of the island was ceded to Hardicanute. This agreement proved of short duration, Harold having contrived, by acts of the most barbarous and deceitful nature, to get the whole kingdom into his own hands. But he enjoyed the fruit of his crimes only four years, when he was succeeded, with the joint consent of Danes and English, by

Hardicanute, A. D. 1039,—whose reign of two years was marked by violence, injustice, and want of feeling, which rendered his sudden death, in a fit of debauch, a cause of congratulation to his subjects. In him terminated the Danish dynasty. The Saxon blood was restored to its regal honours in the person of

Edward the Confessor, A. D. 1041.—This prince had no just title to the throne, there being a nearer descendant of the last Saxon monarch, viz. Edward, son of Edmund Ironside, at that time an exile in Hungary. But the people were so delighted with the idea of a deliverance from a Danish yoke, as to call to the throne any member of their native stock whom they could first find possessing a pretension to sovereignty. This step gave umbrage to the Danes, who contended for the title of Sweyn, the remaining son of Canute. Had this prince consequently been in the island at the time, it is probable that the kingdom would again have been plunged into the miseries of civil war. Edward was enabled to maintain himself in the throne, notwithstanding the murmurs of the Danes, and the intrigues and opposition of his mother Emma, whose unkind behaviour he visited with very unbecoming severity.

His reign was for some time troubled by Earl Godwin, whose daughter he had married, but whose power, deceitfulness, and ambition, were too great to admit of much tranquillity in the critical conjuncture of affairs. On being at last freed from this dangerous man, and from a threatened invasion by Sweyn, Edward employed himself in collecting, arranging, and improving the laws of his country. This was a beneficial task; but the weakness of his mind inclining him to superstition, prevented the attainment of great excellence as a prince. To some constitutional defect rather than to self-denial, ought to be ascribed that chastity for which he was so noted, and which, in place of deserving commendation as a virtue, was rather to be deplored as a misfortune, inasmuch as it precluded the possibility of obtaining an heir to his throne, and consequently might have exposed his country to the hazard of rival claims. Edward is the first English monarch that is said to have cured the disease called king's evil, by touching the patient.

Harold, A. D. 1066,—son of Earl Godwin, ascended the throne without opposition, though Edgar Etheling, grandson of Ironside, was the rightful heir. The people in general, whose affections he had gained, readily favoured his cause, as well from expectation of future benefits as gratitude for past services. Nor were the clergy or nobility backward in sanctioning his elevation. He took effectual means to confirm them all in their good opinions and hopes, so that his reign promised universal satisfaction. But his plans and enjoyment of majesty were speedily interrupted by a message from William, duke of Normandy, demanding the crown of England, in virtue of an agreement formerly made between them, by which Harold had promised to assist that ambitious prince in his designs on the kingdom. Harold was not in a humour to regard any engagement so prejudicial to his own interest, and which, at all events, appears to have been imposed on him when absolutely in the power of his rival. William, again, who asserted that he had been appointed heir by Edward the Confessor, followed up Harold's refusal and defiance by vigorous preparations for invasion. He landed with an immense army at Pevensey, on the coast of Sussex, where he abode for about a fortnight, to refresh his troops, ascertain the state of the public mind, and arrange the plan of his future operations. Harold, in the meantime, conducted his forces from the north, where he had been eminently successful against his brother Tosti, by whom his dominions were attacked. The two armies met at last near Hastings, in Sussex, destined to be the spot on which was fought one of the greatest battles hitherto known in Europe. It terminated the reign and the life of Harold, whose valour repeatedly promised to secure the victory, but whose death, which took place by an arrow, was the signal for the defeat and rout of his countrymen. Nearly fifteen thousand Normans, and a greater number of English, fell in this decisive engagement. Thus ended the Anglo-Saxon dynasty, after a duration of about six centuries. A new order of things commenced with the reign of

William the Conqueror, A. D. 1066.—After returning thanks to heaven on the field of battle, the victorious Norman marched towards London, where the consternation of the people, which at first displayed itself in a vain and dangerous purpose of resistance, at last sought refuge in an offer of the crown. The Duke, with apparent reluctance, but real joy, accepted the boon, and promised protection to the church, deference to the laws, and the impartial administration of justice. His power as a conqueror, therefore, was rendered somewhat less grating to popular feeling, by the semblance of a conditional election. The rest of the kingdom, either from dread of his vengeance, or inability to find a proper opponent to his ambition, acquiesced in this decision; and thus by one adventurous, and undoubtedly rash enterprise, a foreigner, without right or title, found himself firmly placed on the throne of England.

The first measures of William were by no means agreeable to his new subjects. He divided the lands of those who had opposed him among his Norman barons, quartered others of his followers on the religious foundations of the country; disarmed the city of London, and any of the other towns which gave the least shadow of offence to his suspicious mind;

devolved all power into the hands of his own countrymen; and took effectual measures to introduce his native customs, laws, and language, in place of those which were established in the island. Such policy, though severe and ungenerous, was successful. A few commotions, of short continuance, and easily overcome, were the only disquieting events to which his reign was exposed, so far as the people were concerned. But he was less fortunate in his own family, and in his continental dominions. He ended his days abroad, when on a visit to resent a personal insult from the king of France.

William II. A. D. 1087,—was the second surviving son of his father, and succeeded to the throne of England by a will made on the death-bed of that prince. Robert, the elder brother, who had Normandy assigned to him, was the favourite of his countrymen, by whom he was prompted to lay claim to the kingdom, on the ground of primogeniture. Had the activity of his mind borne proportion to the extravagance of his habits, or to the zeal of his friends, he might have proved a very dangerous rival to William. But his indolence ruined his cause.

William, freed from any apprehensions on his brother's account, which had constrained him for a time to court the affections of the English, began to manifest a tyrannical and covetous disposition. His exactions pervaded alike private right and the sacredness of religion. A dangerous illness gave his subjects some prospect of being freed from oppression; but his recovery frustrated their hopes, and shewed the fallacy of those resolutions of repentance with which he had amused the pious credulity of his ecclesiastical attendants. He resumed his former course with additional ardour, as if in revenge for those peevish promises which sickness extorted. A war with Malcolm, king of Scotland, in which he now engaged, was fatal to that prince. This was followed up by an attack on the Welsh, who were equally unfortunate in losing their sovereign. Then occurred a fresh dispute with the duke of Normandy, in which the French first took part against Henry, but were afterwards bribed to relinquish hostilities. He was therefore enabled to prosecute his contest with Robert more advantageously, and, in all probability, would have made himself master of all the dominions belonging to that unfortunate prince, if an incursion from the Welsh had not obliged him, very reluctantly, to return home. These were driven back to their mountains; and the king prepared for another continental expedition. But this was prevented by a conspiracy to dethrone the king, in which Robert de Mowbray, earl of Northumberland, was the chief agent. It bore an alarming aspect, but was speedily dissipated by the vigilance and decision of Henry, who generally contrived to render any disturbance or disaffection a source of additional power and revenue.

A single incident, on a small scale, illustrates part of this prince's character. Anselm, archbishop of Canterbury, rather haughtily maintained the immunities of the church, and, being otherwise offensive, incurred the king's displeasure. Thinking himself roughly treated, he applied for leave to go to Rome. William first refused, but afterwards being well enough pleased to get rid of the prelate, granted him permission. With the intention, however, of passing another indignity on him, as well as profiting by the opportunity, he directed an officer to follow Anselm on his journey, who, overtaking him as he was about to sail, ransacked his luggage, and took away all the money he could find, assigning for a reason, that it was contrary to law to carry the royal coin out of the country.

A zeal for the recovery of the Holy Land from the possession of the infidels, which at this time began to prevail so extensively over Europe, occasioned a circumstance still more gratifying to the temper of William. This was an offer on the part of his brother Robert, who eagerly engaged in an enterprise promising such supereminent reward, to mortgage Normandy for a sum of money which was requisite for his due equipment. The king, relying on his talents as a financier, especially with the wealth of the clergy as materials to work on, instantly promised the stipulated sum of 10,000 marks, which he proceeded to levy with all imaginable dispatch, silencing any murmur or complaint by the hypocritical assertion of the pious motives for such a sacrifice. Thus, Normandy was again united to England,—a connection which entailed a series of wars with France, without ultimate advantage to either country. William himself, though abundantly proud of his bargain, found little or no benefit to accrue from it. The people were fond of independence, and not very well disposed to submit implicitly to his commands. Frequent insurrections among them required his personal exertions; and no sooner was one trouble got over than another arose to disquiet him. These annoyances were far from diminishing his ambition. The earl of Poictiers, intent also on the crusade, but lacking money for the necessary preparations, had recourse to him, with a similar offer to mortgage his dominions, which was accepted with no less eagerness than he had formerly shewn. He was actually engaged in arranging measures for taking possession of the territory thus consigned to him, when he accidentally received a mortal wound from an arrow shot at a stag by Sir Walter Tyrrel, a French knight, who used to accompany him in his hunting excursions. Thus fell William II. denominated Rufus, from the colour of his hair, in the 40th year of his age, unlamented by his subjects, whom he had oppressed, and without legitimate issue to inherit the crown, which he had so unworthily worn for about 13 years. In the 11th year of the reign of this prince was made the last attempt at the invasion of England by any of the northern nations. It was conducted by Magnus, king of Norway, but was successfully opposed by Hugh, earl of Shrewsbury. The practice of agriculture which now began to occupy these people, obviated the necessity, or broke in upon the desire of making hostile visits to foreign countries.

According to a stipulation between them, Robert ought to have succeeded to the sovereignty of England on the demise of William. But that luckless prince, whose courage and generosity contributed to blazon the capture of Jerusalem, had lingered a year in Italy, where his affections were engaged by the accomplished and beautiful daughter of Count Conversana. By this delay he lost the opportunity of establishing his title, and afforded time for his younger brother, then in the island, to secure the royal treasure, the liberal use of which, and an excellent address, supplied the defect of right, and filled the vacant throne in the person of

Henry I. surnamed Beauclerk, A. D. 1100.—Much prudence was needed to maintain the impression by which this usurper, for so he must plainly be considered, acquired his present exaltation. Some temporary concessions, besides their political expediency for the common weal, might, he thought, so rivet the affections of the people, as to make any efforts on his brother's part very inefficient. He soon perceived the advantage of this judicious conduct, when Robert, indignant at such unbrotherly and perfidious behaviour, made a descent from Normandy, with an army to enforce his claims. Several of the nobility, it is true, on hearing of the resolution which brought that prince to England, were disposed to retract their allegiance to Henry, either from a consciousness of the defect of his title, or an apprehension that his present complacency was merely assumed, and would be followed by far less agreeable manifestations. But the influence of Anselm, whom he had recalled, greatly to the satisfaction of the people at large, effectually prevented a general defection, and induced the soldiery to promise fidelity to the king. When the two armies came in sight, accordingly, their respective leaders, foreseeing that more would be lost than gained by a conflict, proposed an accommodation, which was ultimately settled. By this treaty, Robert, in consideration of a certain sum of money, resigned his pretensions to England. He resided for two months with his brother in apparent harmony, and then returned to his own dominions. New animosities afterwards arose between them, but, being adjusted, Robert paid another visit to Henry, and interceded in behalf of some of his adherents, whom the vindictive king had begun to chastise for their indiscreet attachment. The reconciliation was of no long continuance. A more embittered contest than ever took place, the issue of which was destruction to the unfortunate and imprudent, but not unamiable Robert, who, in one battle, lost all his dominions, and, with nearly 10,000 of his men, was made captive. The treatment which he afterwards experienced from Henry forms an indelible stain on the memory of that monarch. He was detained in prison for the remainder of his life, which was of twenty-eight years duration, and, by some historians, is said to have had his eyes put out by order of his resentful brother.

Henry returned in triumph from his Norman expedition, and soon gave evidence, by the haughtiness of his manners and his arbitrary proceedings, that success had made no improvement on his character. The rest of his reign was comparatively quiet, notwithstanding a behaviour on his part which was well calculated to excite the envy of foreigners, and generate dissention among his subjects. His nephew William, son of Robert, supported for a time by the king of France, carried on a very unequal struggle, which had for its object the recovery of his father's dominions. The fortune of Henry prevailed in a decisive battle, in which, though severely wounded, his personal courage obtained the victory. This brought on an accommodation with the French king, who was glad to abandon William's interests for the sake of maintaining his own. The subsequent efforts of the young prince were still more unpromising; and his death, in about eight years afterwards, completely freed his uncle from trouble on his account. The king's disputes with Anselm, about ecclesiastical matters, were neither carried on nor terminated so much to his satisfaction. He incurred popular odium, the prelate being universally considered as the chief bulwark of the Christian faith; he was menaced with a sentence of excommunication by the pope, a judgment which, in those days, entailed very serious evils on the unhappy delinquent; and he was at length under the necessity of resigning the right of granting investitures, by which he had the power of appointing prelates, and which, in fact, was one of the chief articles in the contest.

A domestic calamity, which also affected his political projects, gave a more serious and permanent shock to the prosperity of Henry. This was the loss of his son William, whom he had got recognised as his successor by the states of England, and had just carried over to Normandy to receive homage from the barons of that duchy. In returning from this visit, the prince and many of his companions, belonging to the best families of both countries, were wrecked, through the disorderly conduct and inebriety of the seamen. His own life would have been spared, had not a generous affection for his sister, whose cries he heard aboard the vessel, induced him to attempt her rescue; when too many having rushed into the long-boat, in which he hoped to accomplish his object, occasioned its sinking. Only one person, a butcher of Roüen, is said to have escaped from this catastrophe, by clinging to the mast of the ship. This afflictive event so distressed the king that he was never afterwards observed to smile.

Henry having now no other legitimate son, was anxious to secure the succession to his daughter Matilda, whom he had first married to the emperor Henry V. of Germany, and afterwards, on the death of that monarch, to Geoffrey Plantagenet, so called from a sprig of broom which he wore in his bonnet, eldest son of the count of Anjou. This was among the last objects of his ambition; and he so far at least succeeded in it, as to obtain recognisance and oaths of allegiance from his barons both in England and Normandy. In preparing to return home from this last country, in order to arrest an incursion of the Welsh, he was seized with a violent disorder, said to have been occasioned by eating too freely of lampreys, which put a period to his life in the 67th year of his age. Few princes have displayed such a combination of useful talents and elegant qualities. To a noble and commanding appearance, he joined a courtesy of address, which was requisite to engage the confidence of those whom his dignity, and high reputation in the art of governing, would have awed into timidity and self-distrust. The readiness and force of his eloquence gave full effect to his authority, by impressing a conviction of the superior wis-

Civil history.

dom which actuated his counsels, and a good acquaintance with the literature of his time, which could not have been realised without studious application, indicated the possession of faculties, and a power of will, which in themselves, independent of their consequences and results, are worthy of admiration. In military skill, and personal prowess, he does not seem to have been surpassed, at a time when mankind in general had frequent opportunities of cultivating the art of killing one another. His chief defect, as a monarch, was a resoluteness of temper which endured no obstacle, and often led him to disregard both the opinions and the feelings of his subjects;—his vices, as a man, were inordinate ambition, an unforgiving disposition, and the excessive love of women.

No greater proof of the instability and precariousness of human hopes and designs need be given than the complete failure of Henry's project in favour of his daughter. This originated in a quarter from which, considering his liberality and indulgence, he had anticipated the firmest support. But his own precautions, in reality, defeated his purpose. Thinking to secure their affection, and bind them to maintain his will, by which Matilda was appointed to succeed him in the throne, he heaped favours on Stephen and Henry, the two youngest sons of his sister Adela, who had been married to the count of Blois; and still farther, in the prosecution of his plan, had invited them over to England some years before his death, and, by various grants and honours, raised them to the highest rank among his subjects. Such conduct fostered the ambition of the former of these, and gave him the means of accomplishing a higher destiny. His behaviour and munificence readily procured him favour with the people, nor did he want those qualities which were effectual to obtain esteem from the nobility. There seemed, then, to be required only desire and ingratitude enough on his part to violate, with success, the most sacred, and, certainly, very reasonable injunction of his uncle. These were not long to be looked for in his character. Immediately on hearing of the king's death he quitted Normandy, where he had been on a visit, hastened over to England, and, passing by Dover and Canterbury the citizens of which, aware of his intentions, shut their gates against him, arrived at London, in which he had good reason to believe he should experience a much more gracious reception. Nor was he disappointed. Through the intrigues of his brother, the bishop of Winchester, the vacillation of Corbel, archbishop of Canterbury, the dishonesty of Bigod, steward of the household, who averred that the late king, his master, had on his death-bed disinherited Matilda, and nominated his nephew as heir to the crown, together with the total disregard of the nobles to oaths which they had repeatedly taken, but thought of no moment when policy or interest contended with religion, and the general good will which the populace bore towards him, did this rash and unprincipled adventurer gain access to a throne to which he had no right, and the possession of which he had solemnly sworn it was his duty, and would be his effort, to preserve for the nearest relation of his confiding benefactor.

Stephen, A. D. 1135.—Thus, then, triumphed the lust of power and earthly glory, over some of the strongest obligations by which the feelings, the honour, and the conscience of mankind are imagined to be secured. A victory achieved by such sacrifices demanded no ordinary solicitude and circumspection. The first measures of the new king were of a nature to confirm the only tenure by which he held his sceptre. But the motives and reasons for his granting charters and indulgences, were too conspicuous, and too energetic, to be neglected by those who found either profit or a gratification of vanity in his concessions. Wishes naturally prompted requests, and these gave way to demands, which again multiplied, by a kind of self-production, much beyond the necessities of the case, or the conveniences and just prerogative of the sovereign. Stephen was now involved in a dilemma, in which, perhaps, no wisdom could ensure his safety, but by enforcing an act of justice and retribution by no means agreeable to human nature. It was equally fatal for him, in all likelihood, to attempt to recover his dwindling authority, or to acquiesce in the reiterated devices by which it was fast sinking into insignificance. His temper inclined him to the former expedient; and he therefore began on a suitable occasion, and with the appearance of propriety, by obliging some of his bishops to deliver up their castles, which, in unseemly imitation of the nobility, they had recently erected. This was immediately resented as an insult and breach of charter, by the whole ecclesiastical body, not excepting even his own brother, whose zeal for the church seemed in this instance to exceed regard for so near a relative. Indeed a disgust which had for some time occupied the breast of that prelate, because he had not been admitted into the administration of affairs, as he had expected from his former services, rather induced him to rejoice in an event so opportune to resentment. The dispute was ardent and pertinacious; but in the end Stephen had cause to repent of a step which, however right in itself, and even expedient as a measure of state, was almost certain to give mortal offence to one of the strongest parties in the country, and through their influence to excite a revolt among the people.

In this perilous crisis of Stephen's affairs did Matilda arrive in the kingdom, full of indignation at his conduct, and resolute in her purpose to dethrone him, which the consciousness of a just title, and the promises of some friends in the country, headed by the earl of Gloucester, one of the natural sons of her father, warranted her to entertain. The whole of her retinue at first was only a hundred and forty knights, but this was speedily augmented, so that she thought herself strong enough to contend with the usurper. A civil war now followed, in which the miseries of the country, and the rage of the combatants, were rarely relieved, even in point of effect and appearance, by some of those traits of heroic enterprise and chivalrous generosity, which occasionally radiate the gloomy and terrific conflicts of our species.

After various indecisive engagements, the arms of Matilda were victorious over her rival, in a dreadful battle, fought within sight of Lincoln. The King, who had signalized himself by a valour and intrepidity which would have done honour to any cause, fell into her hands. He was at first treated with respect, but afterwards, on some suspicions, was closely confined to prison, and put in irons. His cause now appeared utterly desperate, since, besides his being entirely in the power of his opponent, his followers were but few and scattered, and disheartened beyond the effort to rally. Every thing, on the contrary, promised gratifications and security to Matilda. Her title was just, which alone, in other times, would have proved a host of strength; her success confirmed her first adherents, and daily attracted more; the clergy in a conference admitted her claims; and the highest dignitary of the church conferred the sanctities of religion on her coronation. Yet were all her fair prospects deceitful, and doomed to be speedily obscured, greatly, if not entirely, by her own imprudence and utter inability to manage those persons and parties by whose influence she had thus far prevailed. A revulsion of public feeling was the consequence, and the bishop of Winchester, who again undertook the cause of his brother, notwithstanding his recent services and oaths to Matilda, contrived to instigate measures which at last drove her from the throne to make way for the captive and humbled, but now restored Stephen. Another civil war ensued, with a similar tissue of disorder, devastation and barbarity. The decision was protracted for some time; but the death of the earl of Gloucester, who had been her chief support, gave a shock to the cause of Matilda from which it never recovered. Still the affairs of the unhappy Stephen were far from being composed. He had incurred the displeasure of the church; his party lay under an interdict from the pope; Matilda still possessed many friends; and though last, not least in the catalogue of evils which threatened his enjoyment, the son of that lady, now approaching to manhood, had exhibited an assemblage of excellencies which could not fail to procure very general esteem and admiration.

This prince, by marriage with Eleanor, heiress of Guienne and Poitou, was enabled to give considerable effect to his hereditary claims, and present a formidable augmentation to the opponents of the English monarch. He landed in the country, where he was immediately joined by most of the barons, took several fortresses, and having rapidly collected a respectable force, advanced to give battle to Stephen. The two armies met near Wallingford, and were about to engage, when the earl of Arundel, one of the king's party, strongly urged the preference of an amicable adjustment, which was agreed to on both sides. Eustace, the eldest son of Stephen, at that time about eighteen years of age, reluctantly beheld the preparations for a treaty, in which he imagined his interests would be materially committed; but his death, which took place during its advancement, removed one of the chief difficulties in the way of its completion. This event, so painful to the king, rendered his accession to the terms more facile and expeditious than might otherwise have been expected. He still demurred, but perceiving the falling away of some of his adherents, and other symptoms of a more disagreeable catastrophe, he consented to settle the succession on his antagonist, while he himself was suffered to retain the crown during his life. Prince Henry now evacuated the kingdom; and Stephen, at last freed from the difficulties which had so long overwhelmed him, began to taste some of the fruits of peace, and to manifest qualities and behaviour which promised the recovery and welfare of his long distracted country, when the arm of death arrested his course in the 50th year of his age. This prince had several virtues. He was brave, generous, merciful; a foe to oppression, a lover of equitable laws; and, possessed of competent abilities for the due government of a nation, he might have stood high in the rank of kings, if an error in the outset of his career, and the temper of the times, had not presented insuperable barriers to the attainment of excellence.

Henry II. A.D. 1154. So decided and universally acknowledged was the title of this prince, that during a period of six weeks which he continued in Normandy after hearing of Stephen's death, not a shadow of opposition, or the least appearance of difficulty, arose to obstruct his accession to the throne. The community, wearied with past dissentions, seemed, with one consent, rather to wait peaceably for the arrival of a master whose authority and power they had neither inclination nor ability to dispute, than to take advantage of a delay so suitable for new commotions. His first measures were perfectly congenial to the reputation he had already acquired for firmness and political sagacity, and appeared calculated to extend the duration of the quiet which now prevailed. He demolished several castles, which had become the repositories of pillage rather than contributed to the welfare of the subject, and fortified or repaired others, as the security of the kingdom might be supposed to require. He dismissed all the foreign soldiery, from whom the people had suffered a good deal of oppression and injury during the preceding reign. He called in the old and adulterate coin, and substituted a new currency, of a proper standard. He granted charters to several towns, by which means the citizens became independent of any superior but himself, and their political liberties were consequently much enhanced. Thus the exorbitant influence of the barons, according to the influence of the feudal government, was impaired, and a vigorous party brought into the state, on which the monarch might rely in some of the most arduous duties of his administration. A more doubtful step was the revocation of some grants made by his predecessors, and the resumption of lands formerly alienated from the crown. The possessors were not a little irritated at their deprivations, and in a few cases absolutely refused submission to his decrees. But resistance was vain, where so great a strength as the king's was always ready to support authority. He even carried his reforming practices so far as actually to reduce certain individuals to the condition of commoners, on whom the late king had bestowed the honour of the peerage, alleging as a reason for such degradation, that these titles were rewards for favouring the cause of an usurper. Nothing but the consciousness of irresistible power could have prompted so prudent a man to adopt such modes of rectifying abuses. He now called a council of state, consisting of the most eminent persons from the nobility and clergy, in which, among several measures for the general security of his government, he consented that the laws of Edward the Confessor, to which the people had been wont to look as the perfection of legislative wisdom, should be in force throughout the kingdom. By this single enactment a sense of safety was diffused over all classes of the community, excepting those whose crimes and evil inclinations awakened in them an alarm of speedy and efficient retribution.

Having accomplished so much for the peace and prosperity of England, Henry was called abroad to oppose the injurious attempts on the provinces of Anjou and Maine, made by his brother Geoffrey. These were frustrated on his appearance, and the people, somewhat shaken by the pretensions of that prince, returned to their allegiance as subjects of the king. An incursion of the Welsh next demanded his care, which was successful in procuring their submission. Then the death of Geoffrey gave him a claim to the territory of Nantz, in which he prevailed over the rival interest of the Duke of Britanny, whose death some years afterwards opened up his title also to that principality. He was not equally fortunate in an attempt to attach the principality of Toulouse to his continental dominions, in right of his wife's mother, only issue of Count William IV. This engaged him in a contest with the king of France, which little benefited either party, and which was at last terminated by the mediation of Pope Alexander III. at that time resident in France, whither he had been driven by the anti-pope Victor IV.

Henry might now have expected that his reign should present little opposition for the future. But it is with princes as with most men. Their difficulties and trials generally arise from unsuspected quarters, and at times when they promise themselves more than usual enjoyment. On his return to England commenced an arduous and protracted collision with the clerical power, in which one of his own subjects, raised to hostile distinction by his liberality, acted a part most injurious to royal feelings. This was the famous Becket, a man of humble origin and insignificant connections, possessed of moderate talents, and rather dubious morality, but insinuating, circumspect, artful, of the most aspiring ambition and ungovernable pride, and a resoluteness of spirit, which, if not engaged merely in the promotion of his own interests, would have merited a very enviable encomium. An account of Henry's curious and eventful dispute with this singular personage has been already given under the word Becket, and need not be repeated. The murder of the prelate, by no means imputable to the king, unless in so far as the expression of dislike on his part excited the barbarous and unprincipled zeal of the assassins, was in reality one of the circumstances in the case most unfortunate to Henry, and which he had the greatest difficulty to surmount with a becoming regard to his own dignity. At this distance of time, and in a very different state of things, a superficial observer could scarcely help reflecting on the abjectness, and seemingly heartfelt nature of his subsequent penance at the shrine of the newly elected saint, as a disparagement both of his innocence and his judgment. But to one who should carefully contemplate the prejudices of the period, and the necessity which Henry experienced of being reconciled to the church, in order to recover the affections of his subjects, his conduct in this trying particular will seem a venial expression of human infirmity, if not a justifiable sacrifice of personal consequence to political expediency. Considered in the latter point of view, it had the merit of success, which, with most men, is an argument of a very satisfactory kind. His effectual opposition to his continental enemies, aided as they were by his own undutiful sons, and his victories over the Scots, with whom he was also at war, were imputed to his renewed favour with the departed martyr,—the general persuasion of which entirely broke up a conspiracy against his government, and enabled him with some comfort to renew his labours for the glory and welfare of his country. By very little effort, a short time before this reconciliation, he had made the conquest of Ireland, which has ever since remained an invaluable appendage to the English crown.

The last years of this great and sagacious monarch were embittered, almost beyond example, by the perverse and unnatural behaviour of his four legitimate sons, who sometimes conspired together, and at other times endeavoured singly, to weaken his authority, dismember his dominions, and, in reality, terminate his reign. The dying, and probably sincere repentance of the eldest of these, whom he had crowned as partner and successor in the kingdom, and the sudden death of another, perhaps the most vicious of the whole, did not produce any effect either in reclaiming or appalling the remaining two. One of these, Richard, now heir to the crown, most perfidiously formed alliance with the king of France, Henry's inveterate enemy, by whose means he was enabled to obtain advantages over his father, which forced him at last to make compliances equally unusual and disagreeable. It was not the least mortifying of these, that the king should grant indemnity to such of his vassals as had entered into the ungenerous confederacy against him. But what was his vexation and grief, when, at the head of the list of those who were thus to be protected from well deserved resentment, he discovered the name of his favourite son John! The sight was too much for parental feeling, already so cruelly disappointed, and now without a shadow of hope that its tenderness could be returned. He expressed himself in the language of despair, regretted the birth of so unhappy a being, and, in an agony of soul, pronounced a curse on his children, which no solicitation afterwards induced him to retract. A lingering fever succeeded to this paroxysm, and ended the miseries of Henry in the 58th year of his age. All the historians relate an occurrence consequent on his death, of a most impressive nature, and which, in days when superstition had so much sway, was interpreted as a divine rebuke. When Richard, already experiencing the pangs of remorse, approached the corpse, blood was seen to gush from its mouth and nostrils. The spectacle struck him with horror; he burst into tears, exclaimed he was the murderer of his father, and acknowledged, in the most pathetic manner, the undutifulness and cruelty of his behaviour.

Thus died Henry II. one of the ablest and best of princes, considered in the various characters of warrior, politician, and legislator. In the less ostentatious, but nevertheless important, and perhaps more trying relations of domestic and private life, it is almost impossible to discover more than one very serious failing; and for this, some allowance, though by no means a justification, will assuredly be made by those who are best acquainted with the manners and licentiousness of his time. The romantic story of the fair Rosamond has its foundation in an illicit indulgence, justly chargeable on this magnanimous and amiable monarch.

Richard I. A. D. 1189.—The conduct of this prince immediately after his accession to the throne, blasted the hopes of his former advisers, and all his companions in rebellion. He dismissed them from his service, and in their place employed those who had loyally adhered to his father, observing, with justice, that those who were faithful to one master would probably be so to another. After he had established himself in the government, he prepared, in the enthusiasm of the times, and according to a vow which he had formerly made, to undertake a military enterprise in the Holy Land. For this purpose, as his love of glory projected the most brilliant schemes, he was obliged to adopt several projects for raising money in addition to what he found in his father's coffers, amounting, as is said, to more than L.900,000, besides jewels. The clergy, who at this time were abundantly wealthy, took advantage of his wants to make purchases very much to their own profit, or the gratification of their worldly vanity, but by no means to the increase of their favour with the people. The sale of lands, jewels, honours, and privileges, not answering his demands, Richard proceeded to other expedients still more impolitic and disgraceful, by which, though he at last succeeded in obtaining his wish, he alienated much of the affection and esteem of his subjects. Nothing but a high opinion of his romantic zeal and ambition of fame, sanctioned by the delusions of the prevalent religion, could have prevented a formidable, if not a fatal convulsion in the kingdom, as the result of his exactions. It is unnecessary to follow him in his wild expedition, fruitful to himself of reputation as an accomplished and fortunate warrior, but utterly unprofitable to his country, or rather indeed decidedly injurious, by its immediate consumpt of blood and treasure, and ultimately by subjecting it in a large sum to redeem him from ignominious imprisonment, inflicted on him when returning home, in defiance of every honourable and generous principle, first by Leopold duke of Austria, and afterwards by Henry VI. emperor of Germany. The whole affair of Richard's detention by this last prince, on groundless charges, and merely in order to gratify his avarice, is perhaps the most flagitious piece of villany which this period, fertile in crimes, holds up to the detestation of mankind. Next to the emperor, the persons most implicated in its baseness, were the king of France, who offered him a large sum to perpetuate the imprisonment of his captive, and the Pope, who, for fear of giving offence to that monarch, refused the most pressing and affecting solicitations to intercede for a man whose life had been so repeatedly and so long exposed in the cause of the church, and whose only crime was the possession of talents, and a display of magnanimity, even in his misfortunes, which excited the hatred of envious and malignant minds.

Civil history.

During Richard's absence, the affairs of his kingdom were in a very perilous condition, through the vices and incapacity of the two prelates to whom the government had been committed, and the traitorous machinations of the worthless John, who was infamous and selfish enough, in opposition to sound policy, to enter into terms with the French monarch, by which the prolongation of his brother's captivity was to be secured, and himself put in possession of the throne. But the reception which proposals to this last effect experienced from the English barons, vindicates them from participation in his iniquitous designs. On arriving in London, after a conference with Philip for the purpose now mentioned, John, giving out that he had received certain intelligence of his brother's death, claimed the crown as nearest heir. They unanimously rejected him, and took effectual measures to oppose his premature pretensions, so that he was obliged to return to France, and at last openly acknowledge his alliance with its sovereign.

The excessive joy of the English at the re-appearance of their monarch in his own dominions, must have greatly delighted a man who, though far from being a faultless character, was not defective in sensibility. Had his prudence kept pace with his feelings, he might have proved as useful as he was acceptable. But a desire to be revenged on his enemy, the king of France, exceeded the regard he ought to have shewn to the welfare of his subjects, who had already suffered more in the way of exactions and contributions than a wise or a merciful sovereign would choose to inflict. Money was requisite to carry his intentions into effect, and money must be had, whatever violations of honour and good faith might be the result. The particulars of the war which he now waged bore no proportion to the enmity that excited it, and are passed over in a cursory manner by the generality of modern historians,—a sufficient evidence of their insignificance and want of interest. One anecdote respecting an interview with his penitent brother, deserves mention. That prince, on being introduced by the queen mother Eleanor, threw himself at the feet of Richard, and begged pardon for his behaviour. "I forgive you, said the king, and wish I could as easily forget your offences, as you will my pardon." The king of France, on the whole, was most injured, for neither party was profited, by the present hostilities. Among the misfortunes he suffered was the loss of all the ancient crown records, which were taken, together with his baggage, in a battle near Blois. Mutual inability to prosecute war, occasioned a truce; and mutual antipathy as readily renewed their aggressions. After some alternations of this kind, in which the folly and vindictive feelings of both were manifested, the Pope's interference promised a more lasting tranquillity between the two combatants.

The death of Richard occurred soon after. He

Civil history.

was shot by a cross-bow from the walls of the castle of Chalus in France, which he was besieging, in consequence of one of his subjects having taken refuge in it with some treasure claimed by the king as superior lord of the land where it had been found. The few excellences remarkable in this prince were fitter to attract admiration in his own age, than to command the good opinion of posterity. He was a brave and high spirited man, full of the enthusiasm of his time, and well skilled in the scanty rules, but arduous practices, of the military art which then prevailed. He had a frank and open temper, and was sincere and ardent in his attachments. But he was proud, revengeful, cruel, greedy of money, indiscriminate and excessive in sensual indulgences. A smart reply of his to a clergyman, who took the liberty of advising him to abandon his vices, especially pride, avarice, and licentiousness, which he denominated the king's three favourite daughters, was at once an avowal of their notoriety, and a display of good-humoured pleasantry: "You counsel well, and I therefore resolve to give the first to the templars, the second to the monks, and the third to the bishops.' Richard had some learning, and is understood to have possessed a genius for poetry, as is indicated by certain productions assigned to him, which are still extant. He was, on the whole, a favourite with the English, though his reign proved highly detrimental to their country, by the very oppressive and arbitrary taxes which he imposed, and his ruinous military contests, which, together with his imprisonment, kept him so much abroad that he spent only a few months at home out of the ten years during which he held the sceptre.

John, A. D. 1199.—Appointed heir to the crown by his brother, John's title was by no means incontestible. He had a rival in his nephew Arthur, son of Geoffrey, whose claims were favoured by the king of France, no longer a friend to John than he conceived likely to advance his purpose of disquieting England. War with that monarch was the consequence. It terminated, after several petty and indecisive engagements, in a treaty, which seemed intended to prevent all future occasions of discord between them. Arthur perceiving that his interests were overlooked, and having reason to distrust the attachment of the French monarch, was at last induced to throw himself on the mercy of his uncle. A little prudence and humanity would now have secured to John at least a comfortable reign, But in the composition of his character there appeared no foundation for either happiness or glory. He soon disgusted his subjects by an unprincipled and totally illegal marriage with Isabella, daughter of count Angouleme, already betrothed, and, in fact, consigned to the count de la Marche, and that, too, during the life of his queen, whom, by some means or other, he contrived to divorce, in order to accomplish his licentious purpose. But, odious as this step might appear, it was exceeded by the removal of Arthur, whom he had made prisoner in the course of a new prosecution of his claims. How this ill-fated prince was put to death, has never been satisfactorily explained. The most probable opinion is, that, after several fruitless endeavours to find a subsidiary ruffian who would undertake his murder, he performed it himself, by stabbing the youth in the very act and posture of supplicating mercy. This is said to have taken place at the castle of Roüen, on the river Seine, into which he cast the body, with a stone fastened to it, so that the horrid deed might not be discovered. All things now went wrong with this barbarous and profligate tyrant. Besides the loss of his continental dominions, he was threatened with a revolt at home, where he was as universally detested as he had formerly been feared. To the difficulties every where thickening around him, he mightily contributed by exciting the indignation of the elergy. The pope, who at one time befriended him, took part in the general opposition, at first by alarming threatenings, and successively by an interdict against the kingdom, which was calculated to excite universal horror and uneasiness, by putting a stop to all religious ordinances; a sentence of excommunication as to the king himself, by which his subjects were absolved from their allegiance; and, at last, by a decree of deposition, which made over the kingdom to his rival, Philip, the French monarch, and called for a general crusade against the object of his spiritual resentment. These measures, extravagant and futile as they would now be reckoned, brought John to a state of total ruin and wretchedness. He submitted himself, with all humility, to the pontiff, acknowledged his vassalage and dependence, consented to accept and to hold his dominions as a fief of the Roman see, and actually prostrated the regalia at the feet of the legate, who made him wait three days for their restoration. Such abject meanness, expedient or politic as it might seem to a man whom every one deserted and despised, and who had, consequently, neither affection nor character to consult, augmented, beyond all bounds, the contempt of the people. The barons, as became them, led the way in expressing the public opinion, and this they did in a manner which, whatever were their motives or their hopes, entitles them to the gratitude of posterity. They assembled, and bound themselves by oaths to united measures for the renewal and observance of a charter of privileges, formerly granted by Henry I. but of which there existed only a single copy, almost totally unknown and neglected in the kingdom. John spurned their presumption, but, perceiving their resoluteness and power, craved time to consider the demands made on him. This was a mere pretence to evade them, but failed in its object. The king appealed to the pope, who espoused the cause of his vassal. But the barons were far less scrupulous than he had been in listening to his remonstrances, at least where politics only were concerned, and, confiding in their strength, proceeded to employ the last measure for obtaining a redress of grievances. After sundry events, calculated, on the one side, to effect, and, on the other, to avoid concessions, it was agreed that the king and barons should meet, on a particular day, at Runnamede, a place between Staines and Windsor, ever since held memorable as the spot on which the *Magna Charta*, or great charter of English liberties, was procured from the sovereign. John rather rapidly yielded the points in debate, and, with great facility, signed and sealed the important documents which were presented by the nobility. This

Civil history.

excited some suspicion of his sincerity, which his subsequent behaviour tended forcibly to confirm. An equitable and really expedient dispensation of political freedom, and salutary privileges to his subjects, appears to have produced in him a feeling of mortification, which neither the contumelious conduct of the pope, nor the insulting treatment he had experienced from the king of France, had been able to excite. In a temporary seclusion from company, which he now affected, he devised means for shaking off the shackles imposed on him. A bull from the former annulled the charter which he had been constrained to sanction, and the arrival of a body of mercenary soldiers, gave him the hope of retrieving the ground he had lost. The barons, grown somewhat careless and inattentive after their former success, were taken by surprise, and suffered various important advantages to be obtained, without any adequate struggle. They were at last so much reduced as to be under the necessity of seeking aid from the king of France, whose son Lewis they offered to acknowledge as sovereign, on condition of receiving immediate protection. This was too tempting a proposal to be resisted. A French army was landed in the country under prince Lewis himself, and was speedily augmented by those who had resisted the king. Affairs now wore the most calamitous appearance for the country, which could not be expected to profit by the success of either party. But a series of events, fortunately for it, disappointed the hopes, and frustrated the plans of both; and the death of John, which took place at Newark, apparently from fever occasioned by grief and anxiety, put an end to the misery and degradation of his subjects. The revolted barons readily swore allegiance to his son Henry, then only nine years of age; the people as readily recognised his hereditary right; and Lewis, after making some ineffectual struggles for the maintenance of the ground he had already gained, was obliged to make peace with the earl of Pembroke, uncle to the young prince, and now appointed protector of the realm, and, with the whole of his troops, to evacuate the kingdom. It is scarcely possible, in the annals of royalty, to find a more worthless character than that of John. Almost every action of his life indicated a base and vicious disposition. It is unnecessary, as it would be disagreeable, therefore, to specify the peculiar failings to which he was subject, and, unhappily for his fame, the assiduity of the historian would be lamentably employed in seeking for any virtue to which they might serve as foils or contrasts.

Henry III. A. D. 1216.—The death of Pembroke, which happened soon after this settlement of the kingdom, was a national loss. He was succeeded by Peter des Roches, bishop of Winchester, and Hubert de Burgh, high justiciary, men of talents and spirit, but rather disposed to arbitrary measures, which suited not the temper of the times, nor the wishes of those whom it was of most consequence to manage well. The king himself, as he reached manhood, indicated rather a feeble understanding, though he was far from being destitute of some excellencies. But even these were occasionally productive of evil, and his whole reign, which was of fifty-six years continuance, proved that a weak prince is nearly as injurious to a nation as a vicious one. A preference for foreigners, the want of economy in his government, and the consequent adoption of oppressive modes of acquiring money, gave general discontent, and excited a factious spirit, which frequently endangered his throne. The most formidable assailant whom his imprudence, general want of success, and disregard to the rights and welfare of the people, raised up against him, was his brother-in-law, Monfort, the earl of Leicester.

Civil history.

By this nobleman's machinations a plan was at last formed for bringing the king to a necessity of meliorating his government, if not of entirely depriving him of it. Henry was compelled, in the critical conjuncture of his affairs, to promise the redress demanded, and actually to consent to the nomination of twenty-four barons, empowered to manage and model the regal power for the good of the community. It was to this body, over which Leicester himself presided, that England was indebted for the first rude draught of a House of Commons, one of their earliest proposals being an order for four knights to be chosen from each county, with power to examine into the grievances and wants of their constituents, and to lodge information of the same at their personal attendance on parliament. It is quite obvious, that in this measure, as in the whole of their proceedings, the barons were much more intent on aggrandising themselves, than on giving consequence and political agency to the people, for they pursued a system which promised eventually to sink all power in their own hands. Thus it is certain that an aristocracy, or oligarchy, must have speedily been established, had not opposition sprung up in the very body which they thus called into existence. The representatives of the people, now in the habit of assembling in a separate house, where they could deliberate on their own concerns and interests, both perceived and remonstrated against the impropriety of some of their measures, and did not fail to represent, in an unfavourable point of view, the contrast between the king's celerity in performing the conditions required of him; and their dilatoriness in accomplishing any thing for the public good. Not content with this spirited conduct, those patriotic men ventured even to claim the assistance of prince Edward, the king's eldest son, at that time upwards of twenty years of age, and whose talents pointed him out as likely to be of the greatest service, in settling the affairs of the nation.

The barons, seeing the urgency for some appearances calculated to appease the rising dissatisfaction, published a new code of laws, of little utility, but which they thought would, at least, have the effect of amusing the people, while they should more effectually secure their power. When the farce could be no longer continued, a parliament was called at the instance of Edward, in which the king resumed his power, after some fruitless efforts on the part of the barons to get possession of his person. Leicester, so far disappointed in his views of attaining and preserving the supreme authority, at length raised a formidable force, with which he defeated the royal army, commanded by the king and the prince, both of whom had the misfortune to be taken prisoners. The former he carried about with him from place to place, and obliged to give orders for the delivery of several fortresses into his hands, and to ratify the measures which he judged necessary for his own successful usurpation; and Edward he confined, at least for a time, in the castle of Dover. Leicester, however, was not so powerful as to be set above fear. He found it expedient to summon a parliament, in which, besides two knights from every shire, deputies from the boroughs were ordered to be returned,—a still more decided approach than had ever hitherto been made towards the constitution of an English House of Commons.

This assembly, far from answering his expectations, decided on the re-establishment of the ancient national government, and so conducted their deliberations as to induce Leicester to acquiesce in the wishes of the people. He therefore set Edward at liberty, though he still continued to watch over his motions in the most jealous manner, as if he had foreseen or dreaded the termination of all his earthly prospects in the enterprising and ardent spirit of that prince. But all his stratagems proved abortive. An opportunity presented which Edward longed for. He effected his escape, collected some forces together, and very unexpectedly for Leicester advanced to engage him at Evesham. This terminated fatally to that ambitious nobleman, who soon perceived the extreme danger of his situation, but whose intrepid valour for a time suspended the decision of victory. The aged and helpless Henry, whom he had barbarously constrained to take his station in the front of the battle, was wounded in the shoulder, and, not being recognized by his friends, would have certainly been killed, had he not cried out, "I am Henry of Winchester, your king," which immediately brought the conquering Edward to his rescue.

The royal cause, so brilliantly sustained, now flourished everywhere; and it is to the credit of the victor that he did not follow up his success by any undue severities on the vanquished and those who had favoured them, or any attempt to stretch the prerogatives of the crown beyond their former and ascertained limits. Edward, after establishing the tranquillity of the nation under the mild government of his father, embarked in the last crusade with Lewis XI. which he greatly distinguished by his valour and zeal. Having concluded an honourable treaty with the sultan of Babylon for ten years, he was on his return home when he received tidings of the event which immediately devolved the cares and the glory of the crown on his own head. It was a memorable reply which he made to the king of Sicily, who observed how much less affected he appeared on hearing at the same time of the death of his infant son, "The loss of a son is light, because I may have another, but that of a parent is great, because it cannot be repaired." Though in reality, during the Saxon period, there had been no less than three monarchs of the same name, this prince was crowned, and has always been designated, by the title of

Edward I. A. D. 1272.—The affairs of the kingdom were wisely managed during his absence, which lasted near a year after Henry's death, by a regency chosen by the barons, all of whom were ready to swear fealty to one whose right was incontestible, and whose character and talents seemed so eminently to qualify him for the throne. On his arrival, therefore, he found a state of universal tranquillity, which enabled him at once to set about rectifying some of the disorders that had arisen in the preceding reign, and to establish a rigid administration of justice throughout the country. This was highly commendable, and produced the most beneficial effects; but it was not sufficient to occupy his active mind, or to gratify all the desires of his heart. He was naturally ambitious, and possessed a haughtiness of spirit which, besides that it could brook no real offence aimed at his dignity or his interest, was apt to take alarm even at the creatures of his own imagination. And, to all this, he added a severity of judgment and feeling, which both prescribed the full amount of recompense and exacted its accomplishment. A dislike, founded on prejudice and perhaps religious opinion, drew forth a cruel and impolitic persecution of the numerous Jews who now resided in England, which is certainly a stain on his government. This was followed by a powerful enterprise against the Welsh, who had incurred his resentment, which effected the complete conquest of their country, but was not finished without a display of remorseless vengeance quite inconsistent with the character of a truly great man. It was on the traditionary, but, it is believed, authentic circumstance of his having put to death all the bards of that romantic province, whom he imagined, not without truth, to preserve the flame of heroic valour by their poetry, that Gray has founded his soul-appalling ode:

> "Ruin seize thee, ruthless king!
> Confusion on thy banners wait," &c.

The annexation of Wales to his other dominions, however brought about, was a political measure from which the greatest benefits have ever since been derived. Edward, soon after this event, had a still more splendid opportunity afforded him for the display of his military talents, and the gratification of his ambitious desires. Alexander III. king of Scotland, having died without male issue, two competitors for the crown arose in the persons of Bruce and Baliol, both descended from David I. by the female line, and whose rival claims were supported by the respective friends and adherents of the parties. The parliament of Scotland, perceiving the critical situation of affairs, and dreading the occurrence of a civil war, which must devastate the country, came to the resolution of applying to Edward to undertake the office of umpire between the opponents. Nothing could be more agreeable to this monarch than a proposal which not only promised to require his interference in a manner that might conduce to the extension of his power, but also furnished a pretext for reviving his own pretensions to a feudal superiority over that country,—a claim, indeed, hitherto so little known, or so extremely remote and trivial, as not once to have proved an argument or a reason for the Scottish barons avoiding such an occasion of bringing it again into notice. The proofs which he now adduced in behalf of his assertions were no less contemptible than his design was iniquitous. He seems to have been aware of their incompetency, and therefore took good care to furnish himself with a more convincing logic, by marching to the frontiers of the kingdom with a large army, ready to silence every objection, and take possession of the reverted estate. The parliament, and the whole people of Scotland, thunderstruck at a pretension of which no one had ever so much as dreamed, perceived, when it was too late, the blunder which had been committed, but knew of no mode of avoiding the dreadful consequences of resistance. Edward interpreted their silence as a consent to his claims,—and after requiring the competitors, who were now no less than nine more than the original pair, to acknowledge his superiority, proceeded to give sentence on the subject referred to his arbitration.

The crown was adjudged, perhaps on the best grounds, to Baliol, who immediately did homage to the English monarch as his lord paramount. Nor ought this acquiescence to be so severely censured in that individual, as has often been done, with the view of exalting the spirit of the unsuccessful Bruce, who in reality had been the first to acknowledge the king's superiority,—all the rest of the claimants, and, in fact, the barons at large, being abundantly ready to imitate his example, when they saw the power by which they were menaced, or had any hopes of advantage from their obsequiousness. Baliol soon after renounced his allegiance, which so provoked Edward that he invaded Scotland with a large army, and compelled him to resign the kingdom into his own hands. At this period appeared the renowned Sir William Wallace, to restore, in some degree, the drooping and degraded honour of his native land. With a few patriotic souls he ventured to attack some of the English garrisons, with such success as speedily augmented his numbers, and gave hopes of rescuing Scotland from the gripe of a foreign usurper. The earl of Warenne, appointed governor of the country by Edward, having retired to the north of England for reinforcements, now advanced with an army of 40,000 men to oppose him. A battle, fought at Stirling, in which the Scots were completely victorious, forced that general once more to retreat, and at last evacuate the kingdom. Wallace now assumed the title of governor of Scotland, under Baliol, then a captive with Edward. This, together with his supereminent merits, produced rather envy among the nobles, than any adequate co-operation. He resigned his authority, and contented himself with the command of those who would have no other leader. Edward hastened to retrieve his losses. He came up with the Scots at Falkirk, and defeated them with great slaughter. Still were that people far from being subdued. Various engagements afterwards took place, in which the English were by no means successful. The vexatious resistance at last instigated Edward to the greatest activity, and to the adoption of measures which have entailed just odium on his name. Wallace, betrayed into his hands, was ignominiously put to death. This more than ever exasperated his countrymen, who wanted only a leader of spirit to conduct them to revenge. Such a character was presented in Robert Bruce, the grandson of the unsuccessful competitor for the crown. This heroic man, disdaining the trammels which his immediate ancestors had meanly borne, raised the standard of rebellion in his native land, and waged defiance against the English monarch, as its enemy and oppressor. The English were again driven out of Scotland, but returned with additional forces, which, falling unexpectedly on Bruce, put his army to rout, but in no degree subdued his resolution. Edward himself, vowing a signal chastisement on a nation which, though twice conquered by himself, maintained its independence, and thwarted his ambition, hastened to the frontiers, when he sickened and died, near Carlisle, but not without enjoining his son to prosecute, without delay, his vindictive designs on that kingdom.

The reign of Edward, which lasted thirty-five years, was singularly advantageous to England. He enhanced its character, vastly improved and strengthened its laws, and by ratifying the *Magna Charta*, not willingly indeed, for he was in heart a despot, gave a security to the subject, which had never before been enjoyed. In ability, military talent, and valour, activity, and vigour of mind, this monarch was never surpassed by any prince that inherited the crown of England.

Edward II. A. D. 1307.—A contrast to his father, by his weakness, indolent habits, and unworthy attachments, this prince soon disappointed the hopes which had been entertained from his apparently amiable disposition, and freedom from any remarkable vices. His reign was inglorious, and terminated unhappily. Piers Gaveston, an accomplished, but debauched youth, whom he had made his confidant, disgusted the nobles by his vanity and haughtiness, and was at last, with considerable difficulty, abandoned to their vengeance. Edward slowly proceeded to follow up his father's advice as to Scotland, but seemed to think the expedition rather a source of amusement and pageantry, than accompanied with hazard, and requiring some personal sacrifices. His army, which amounted to about 100,000 men, having entered the country, was met at Bannockburn, within two miles of Stirling, by Bruce, whose troops were not so much as a third part of that number, but were animated by a leader and a determination which made them greatly superior to their opponents. So signal a defeat as the English here experienced, has rarely occurred. Their loss has been rated at half their amount, but this seems an exaggeration. The King himself narrowly escaped; and such was the impression which this calamity produced, that no advantage in number or circumstances could induce the invaders to face the Scots for some years afterwards.

Edward endeavoured to console himself with a new favourite, who became as odious to the nation as the former. Disaffection among the nobles, the intrigues of his profligate queen, and a series of imprudent and pusillanimous proceedings on his own part, brought on his deposition by parliament, as incompetent and unworthy to fill the throne. He was afterwards confined to prison, where the malice of some of his enemies still pursuing him, put a period to his days in a manner most shocking to humanity.

Edward III. A. D. 1327,—was only 14 years of

Civil history.

age when he received the crown. He avenged the death of his father, by the perpetual imprisonment of his own mother, and the execution of Mortimer, her worthless paramour, who had brought it about. Then resolving on the recovery of national honour and his hereditary claims, he marched into Scotland, where, after some successes, he placed his tributary Edward Baliol on the throne, though he could not reconcile the people to his authority. To this enterprise succeeded his vigorous and well supported pretensions to the crown of France, which he claimed in right of his mother, on the death of Charles IV. without male issue. In prosecution of this splendid object, he carried an army to the continent, where he obtained a signal victory over Philip of Valois, who now supplied the vacancy. This was on the field of Cressy, where 100,000 French under that prince were completely routed by the English, amounting only to 30,000, commanded by Edward himself, and his illustrious son, generally called the Black Prince. In the mean time, the Scots, who had invaded England, were defeated by his queen Philippa, and their monarch David II. taken prisoner. A peace concluded between Edward and Philip, through the mediation of the pope, was broken on the death of Philip, who was succeeded in the throne of France by his son John. This monarch assembling an army, so hemmed in the English under their valiant hero the Black Prince, near Poictiers, that it seemed impracticable for them to escape destruction. He proposed, therefore, their absolute surrender, which was indignantly refused. Yet, even here, the fortune of England prevailed. The French were beaten, and John himself was numbered among the captives, and carried to London, now gratified by the spectacle of two royal prisoners. But these and other advantages little aided Edward in his ambition. He obtained, indeed, much glory, and several provinces were ceded to him; but he found it necessary to renounce the claim which had prompted him to such an expensive enterprise. The death of his magnanimous son was an affliction which so distressed him, that he became unwilling and unable to attend to public concerns. This was equally injurious to his government, his reputation, and his comfort. Those whom he trusted were unworthy of confidence which they abused, and those from whom he had a right to expect gratitude and affection, first plundered, and then deserted him,—a sad example of the instability of worldly greatness. He died about a year after his son. This reign was peculiarly oppressive to England, by the amount of taxes which were required to support the military expeditions. It was Edward III. who instituted the order of the garter. In his time the French language was abolished from law pleadings, which were formerly carried on in it.

Richard II. A. D. 1377,—succeeding to his grandfather in the eleventh year of his age, the government was vested in his three uncles, the dukes of Lancaster, York, and Gloucester, whose differences of temper, and contests for power, in addition to the feebleness and imprudence of the prince, involved the nation in great disorder and perplexity. It had suffered much from the extravagance of the preceding reign, but was threatened with still greater hardships by the mismanagement and misfortunes of the present. Among other modes of replenishing the exhausted treasury, a tax of three groats on every person above fifteen, excited peculiar indignation among the lower orders, who were thus made liable in the same amount as the rich, and who, besides this just objection, had reason to complain of the manner in which it was exacted. An insurrection, under the noted Wat Tyler, was the consequence, which had a most alarming aspect, and was with difficulty allayed. The king's liberal promises, made in a spirited manner, at a critical time, won favour with the populace, which his subsequent behaviour altogether belied. The nobles, who afterwards instituted an opposition to the administration and prerogatives of the sovereign, were more pertinacious and more effectual in their designs. Richard occasionally exhibited a firmness and resolution which augured their complete subjection; but he wanted judgment to guide him in such trying emergencies, and usually destroyed by violence, or suffered to escape by indolence and love of pleasure, the opportunities for establishing a vigorous and salutary government. A conspiracy against him, detected in time, gave the commons occasion to shew their loyalty, which a wise prince would have turned to good account. But his evil fortune prevailed. The duke of Hereford, son of the duke of Lancaster, whom he had offended and banished, taking advantage of the king's absence in Ireland, collected his followers and the disaffected, with whom he rose in open rebellion against his sovereign. The unfortunate Richard fell into his hands almost immediately on arriving in the country, and was committed a prisoner to the tower, where, after being compelled to resign the crown in favour of that nobleman, a measure which the parliament basely confirmed by a special deposition, on very inadequate, though by no means altogether unfounded charges, he was either privately assassinated, or, as is more probable, was starved to death, in the 34th year of his age. He died without issue; and now, therefore, was laid the foundation of those contentions between the houses of York and Lancaster, which so long afterwards involved the country in blood and desolation.

Henry IV. A. D. 1399.—A crown unjustly acquired is rarely enjoyed. It was impossible for men not to recollect and to blame the means by which Henry had risen to his present elevation. Nor was secret dislike, or even open censure, the only source of disquietude which he had to apprehend. The superior pretensions of Mortimer, heir of the house of York, stood ever in the way of his own hereditary claims; and, on the other hand, he had neither inclination, nor saw it expedient, to rest his title solely on the consent of the people. His right, accordingly, seemed at last reducible to possession merely; and how precarious this was might be readily understood from his own success, and a single glance at the characters and tempers of the nobility who had either favoured or opposed his cause. One benefit accruing from his uneasy convictions and his fears was an activity of mind, which rapidly perceived the approach of danger, and no less rapidly provided against it. His numerous assailants, on the contrary, were unhappy in the want of concert and combination; and though formidable enough, in all probability, to effect his ruin, rather waited their turn to be destroyed, than hastened to do justice to the motives which actuated their rebellion. The earls of Kent, Salisbury, and Huntingdon, lords Spencer and Lumley, who were among the first to conspire against him, paid the forfeit of their ineffectual resistance by their lives; a more spirited, but not more skilfully managed insurrection, under the earl of Northumberland, was defeated in a dreadful battle at Shrewsbury, where that nobleman's son, Henry Percy, surnamed Hotspur, who commanded, lost his life; then followed a confederacy between the archbishop of York, the earls of Nottingham and Northumberland, which last the king had pardoned only a short time before, and other leaders, to place young Mortimer on the throne, but which was speedily broken by the artful negociations of the earl of Shrewsbury, when the prelate and Nottingham were beheaded, Northumberland escaping the like fate by flying into Scotland.

To these difficulties, and a long continued, though not highly important state of hostilities with Owen Glendour, a descendant of the royal family of Wales, all so happily overcome, succeeded a very different sort of uneasiness, in which Henry's conduct, politically judicious as it might seem, was far less to his honour. This was a contest between the *orthodox* clergy and the disciples of the illustrious Wickliffe, in which the former so far prevailed over the scruples, or it may be called conscience of the king, and the reluctance of the House of Commons, as to obtain an act for the preservation of the faith and purity of the church, by the burning of those who were ignorant or stupid enough, or had the misfortune to think differently from the established creed! William Sawtre, rector of St Osithe's, London, was the first person burned alive in England for his religious opinions; an example of absurd and detestable severity, which the madness of ecclesiastical zeal was for long afterwards busied in imitating with awful success.

The tranquillity which his triumph over all his enemies, and a tolerable good understanding with Parliament, now promised, was disturbed by the excesses and profligacy of his eldest son, and still more, there is reason to believe, by the tumults of an agonizing conscience, which no worldly prosperity can assuage. His health declined apace; he became subject to fits, which at times bereft him of his senses; he shewed a perpetual apprehension of his losing the crown, which he had always placed on his pillow when he went to bed, lest it should be seized before his death; he vowed taking the cross, and fighting the cause of the pilgrims in the Holy land, in the event of his recovering; he counselled the prince of Wales as to the conduct he ought to adopt, not concealing from him his own doubts as to the validity of the title by which he had ascended the throne, and recommending that generous and now repentant youth to the protection of heaven, breathed his last in the 46th year of his age.

Henry V. A. D. 1413.—A solitary ray in the beclouded character of this prince, on which men had been accustomed to gaze with mingled emotions of hope and apprehension, broke into meridian splendour, when he found himself arrayed in royalty at the head of a great and expectant nation. His youthful companions in scenes of riot and debauchery were dismissed, but not without the most cordial exhortations to reform, and, at the same time, some more substantial evidences of his generous attachment; the faithful servants of his father, again, some of whom had given cause, though no reason for offence, were honoured with his confidence and employment; and, on all hands, it appeared to be his strenuous determination to cancel the recollection of his former misbehaviour, as well as the disorders of the state, by virtuous conduct and a wise administration. One error, of no trivial nature, indeed, he did not escape, though even in it he displayed a good sense and humanity of disposition, which, in an age of less bigotry, would have secured his reputation from censure. This was the giving up of Lord Cobham, accused of heresy, to the zeal of Arundel, archbishop of Canterbury. The conduct of that nobleman, it must be confessed, was not blameless; but then the crime, for which he ultimately suffered, was in a great degree the product of that religious persecution to which the king was induced to lend his sanction.

But it was the military talent of Henry, and more especially its splendid exercise against France, which procured the chief admiration of his subjects. Taking advantage of the distractions of that kingdom as favourable for the demand and recovery of some provinces formerly ceded, Henry, on refusal, prepared for invasion. A large army, which he landed at Harfleur for this purpose, became so enfeebled by disease, as apparently to present an easy prey to the enemy, who began to calculate on the amount of ransom which they should receive for their intended captives. The battle of Agincourt, therefore, was the most fortunate event which a mind ambitious of glory could desire. In several respects it resembled the battles of Cressy and Poictiers, the fame of which, indeed, seems to have mightily conduced to the astonishing valour, as well as the very improbable success of the English; but it was more fatal to France than either of them in the number of eminent persons who were taken and slain, and no less remarkable in the extreme disproportion of the loss on the part of the victors. It did not, however, obviate the necessity which Henry experienced, of retiring to England, in order to raise more men for the prosecution of his enterprise. With these he returned in the following year, and after inconsiderable opposition, and various negociations, marched to the very gates of Paris, the citizens of which, by timely agreement, obtained a truce. A treaty was now entered into between Henry and the Queen-mother, in which the duke of Burgundy, keeper of the insane or imbecile Charles VI. concurred, to the prejudice of the Dauphin. By this treaty, Henry was to espouse the princess Catherine, daughter of that monarch, and to receive the kingdom of France as her dowry, the crown of which, with all its rights and dominions, was to remain, after the death of her father, with him and his heirs, and the government of which he was now to undertake, in consideration of the king of France's frequent infirmities. The marriage was soon afterwards consummated, and Henry took formal possession of Paris, where he obtained a ratification of the preceding compact, and the oaths of allegiance from the French nobility.

There still remained an antagonist in the person of the Dauphin, against whom, therefore, he turned his victorious arms. But the contest necessarily exhausting his troops, the king had to return to England in order to provide himself with additional force. This conquest flattered the pride of his subjects, but promised them little benefit; nor could they contemplate the union of France and England under one monarch, without a well-grounded conviction that the latter would dwindle into a mere province. The parliament, therefore, shewed an unwillingness to grant him the full amount of supplies which he needed; but in this exigency he had, besides their aid, the contributions which he had levied on the conquered provinces, and accordingly soon assembled a new army of nearly 30,000 men, with which he landed at Calais. The Dauphin had not been idle during his absence, but, with great exertions, having raised a respectable force, consisting partly of a body of men sent to his assistance by the regent of Scotland, was enabled to attack the duke of Clarence, commander of the English troops, and obtain a complete victory. This advantage was soon checked by the arrival of Henry; and the Dauphin, now obliged to retire beyond the Loire, seemed driven to the very brink of destruction, when the fatal illness of his too powerful rival turned the tide of fortune in his favour. Though at the very summit of his glory, and only thirty-four years of age, Henry observed the increase of his disorder, and the approach of death, with apparent composure. He called for some of his principal nobles, and, among the rest, his brother the duke of Bedford, to whom he consigned his will regarding the government and his family, and recommended the protection and care of his son, then an infant, not quite a year old. The short remainder of his time was passed in devotion, when he expired in great tranquillity. The English historians fail to notice a single defect in the character of this prince; from the French, again, to whom it is certain he proved a most grievous foe, his reputation has received several not unimportant drawbacks. They charge him with cruelty, haughtiness, avarice, and ambition. Assuredly, some of his actions might appear to bear out each of these imputations. But the criticism which has so rigorously traced out the connection, is more to be wondered at for its industry than praised for its candour.

Henry VI. A. D. 1422.—During the minority of this prince, his uncles, the dukes of Bedford and Gloucester, were appointed protectors or guardians of the kingdom, the latter officiating in England during the absence of the former in France, where he had to conduct the war against the Dauphin. For some time the English army, accustomed to victory, and still commanded by an able and experienced officer, scarcely perceived the loss of their heroic monarch. But the face of affairs was entirely altered when, on the death of Charles VI. which soon afterwards took place, the Dauphin assumed the title of king of France, and in that capacity had the satisfaction of witnessing the gradual return of his countrymen to their natural allegiance. The success which now attended this long unfortunate prince was accelerated in a surprising degree by means which, in our day, would be considered most absurd and insignificant, but which the superstition of the times rendered abundantly efficacious. A country girl, called Joan of Arc, prompted by religious and patriotic enthusiasm, gave herself out as directed and commissioned from heaven to undertake the deliverance of France from the power of its invaders. Her pretensions, for some time ridiculed, were at last sanctioned by the courtiers of the new king, and employed to revive the courage of his desponding adherents. Under her apparent guidance, several advantages were gained over the English, who now became no less convinced of the authenticity of her mission than they were sensible of its overwhelming effects. Their ardour was proportionally damped, and for some time their losses threatened their entire ruin. Nor was their cause bettered on the breaking up of the delusion, by the capture of the marvellous object of their dread, whom they afterwards most unjustly and cruelly put to death on a charge of witchcraft. The duke of Burgundy, whose alliance had so materially aided their enterprise against his country, now perceiving the error and impolicy of his conduct, concluded a treaty with Charles, which left the English in the most hopeless condition. Their utmost exertions availed them not, and they were at last obliged to abandon the whole of their conquests, with the exception of Calais,—a miserable compensation for the blood and treasure which had for ages been squandered in the foolish attempt to annex a foreign kingdom to their native dominions. The death of the duke of Bedford, one of the greatest men whom the history of England presents to admiration, occurred a few days after the treaty which decided the continental interests of his country.

The remainder of Henry's minority was distracted by the violent factions between the duke of Gloucester and the cardinal of Winchester, to whom his education had been committed. His own imbecility, which soon became apparent, and rather increased as he advanced to manhood, prolonged the influence of the latter, by whom he was at last induced to marry Margaret of Anjou, a woman of extraordinary talents and spirit. This princess co-operated with the cardinal in opposing Gloucester, whose death, not without universal suspicion to their disadvantage, was followed almost immediately by that of his rival. But the tranquillity of England was now to be assailed in a much more deplorable manner, by the appearance and pretensions of a claimant of the crown in the person of Richard duke of York, a descendant, by his mother's side, of Lionel, the second son of Edward III. and elder brother of John of Gaunt, the forefather of the present sovereign, whose incapacity offered a fair opportunity for reviving a title which undoubtedly stood preferable on the ground of hereditary succession, but which circumstances had rendered it imprudent to urge at an earlier period. Thus much as to the point at issue between the rival parties, which, under the ensigns of a white rose appropriated by the house of York, and a red rose by that of Lancaster, now began to deluge the kingdom with blood.

Civil history.

The duke of York, a cautious and moderate man, did not at once disclose his intentions, even when his appointment of protector of the kingdom, during an illness of Henry, gave him a favourable opening. His enemies availed themselves of his slowness, and induced Henry, on the appearance of convalescence, to deprive him of that honour, and confer it on the duke of Somerset. In the first battle, which was fought at St Albans, after sundry manœuvres and stratagems on both sides, the king had the misfortune to fall into the hands of Richard, who treated him with great respect, and used his success no farther than to induce that feeble prince to commit the authority of the crown again into his hands, a measure afterwards ratified by parliament. The queen, some time afterwards, got her husband to resume the government, rallied the remains of the Lancastrian party, but was defeated in a battle at Northampton, when Henry was again made prisoner. Richard, still exceeding in caution, now very gently proposed his claims to the House of Peers, who, with some members of the Commons, at last gave a decision intended to please all parties, acknowledging the title of the duke of York, consigning the government to his care during the lifetime of Henry, who was to retain the title and dignity of king, and prescribing his succession on the death of that prince. The moderation of the duke, and the easily managed disposition of Henry, now a prisoner besides, produced acquiescence in this sentence.

But the queen, less inclined to any such compromise, had in the mean time assembled an army, with which she hoped to recover the power of her husband. The duke, taken by surprise, unadvisedly ventured on an engagement at Wakefield, with very inferior numbers, when he was defeated and slain. This might have been expected to terminate the contest between the two parties. But it was far otherwise. The earl of March, son and heir of that nobleman, obtaining some advantages over the earl of Pembroke, one of Margaret's adherents, advanced against her, animated as she was by recent success in another battle at St Alban's, which brought the king again into her hands. She now found it necessary to retreat, therefore, and left her rival a free passage into the capital, where he was well received, and in a short time, by a sort of popular election, and through the predominant influence of the earl of Warwick, commonly called the *King-maker*, proclaimed king, by the title of

Edward IV. A. D. 1461.—This elevation was not to be peaceably enjoyed. Margaret, persevering in her efforts, soon found herself able to raise an army of 60,000 men in the north, with which she resolved to encounter her opponent. Edward, and his chief adviser Warwick, at the head of 40,000, hastened down to Yorkshire. The armies met near Towton, a small village in that county, where one of the most sanguinary battles recorded in the history of England since the conquest was fought. Edward, in whose composition there was little of the "milk of human kindness," had ordered that no quarter should be given; and indeed the parties were so inveterate in their hostility, that such a command was very superfluous, if mutual destruction were the object aimed at. Above 36,000 men are said to have fallen. The victory was decisive on the side of the Yorkists. Margaret and her husband fled into Scotland. She afterwards obtained a small supply of men, with which she ventured again to enter the kingdom. These were defeated at Hexham, when her cause became so utterly desperate that she and her husband were forced to seek their safety in separate flight. The wretched Henry thought to conceal himself in England, but was discovered and carried prisoner to London. Margaret escaped, after some perilous adventures, to the court of her father, where her retainers lived for some time in the greatest indigence.

Civil history.

Edward, now freed from his enemies, began to indulge in a medley of licentiousness and cruelty, of which there are few parallels. His conduct proving likely to render him unpopular, except among the dissolute and profligate, the earl of Warwick endeavoured to recover him from his vicious excesses, by a proposal of marriage with the Lady Bona of Savoy, but was at last so disgusted and offended at his privately espousing Lady Grey, while he himself was actually engaged in a negociation for effecting that foreign alliance, that he abandoned the king's interest, and entered into a combination against him with the duke of Clarence, Edward's second brother, and several of the nobility, who took alarm at some measures of his administration. Opportunities were not long wanting to call forth the manifestations of their resentment. Plots, conspiracies, stratagems, and insurrections succeeded each other with fearful rapidity. Warwick, forced to flee to the continent, obtained assistance from the king of France, which enabled him to invade the kingdom, and revive the hopes of the Lancastrian party, with whom he had now connected himself. Edward, vainly confiding in his security, was surprised, and with much difficulty escaped into Holland, so affording the enterprising *king-maker* another occasion for the exercise of his creative power. Henry, now released from the tower, was again, by his means, seated on the vacant throne; and a parliament which was summoned gave authority to the change, and busied itself in reversing all that had been done in the preceding reign.

But the process of revolution was not yet completed. Edward, an exile in Holland, procured some forces from the duke of Burgundy. With these and his few followers he landed in Yorkshire, where, though at first he was coolly received, he gradually accumulated an army, which enabled him to march to London, and seize on the person of the unfortunate Henry, who was again conveyed to his old mansion in the tower. The influence of Warwick, beginning to decline, was vastly weakened by the defection of Clarence, who went over to the cause of his brother with a body of 12,000 men. Naturally impatient, accustomed to overcome, and being disinclined to share any eventual success with Margaret, whose arrival was every day expected, this extraordinary character, rejecting the terms of peace which were now offered him by the two brothers, prepared to accept the boon of fortune, by venturing on a battle at Barnet, within ten miles of the capital. This was decisive of his efforts and his life. He

Civil history.

fought with amazing valour, repeatedly eyed the goal of victory with an emotion more grateful even than hope, but at last perceiving the injurious consequences of a mistake of cognizances, which no art or courage on his part could retrieve, plunged among the thickest of the combatants, and fell.

The unfortunate but magnanimous Margaret, aided by the Duke of Somerset, made a last struggle at Tewkesbury, where she and her son, the prince of Wales, were made prisoners. This youth, heroically, rather than prudently, vindicating his invasion in the presence of Edward, was struck on the mouth by the gauntlet of that prince, which served as an excitement to the dukes of Gloucester and Clarence to butcher him almost on the spot. Henry died a few days after the battle, not without suspicion of the former nobleman's deed, and Margaret herself was ransomed by the king of France, where she terminated her miseries after a few years of privacy.

Edward had now entire leisure, on one hand, to gratify his revenge on his adversaries, by executions and confiscations, and on the other hand to wallow in those pleasures, the indulgence of which, it might seem, constituted his whole idea of royal felicity. The series of his debauchery was a little broken by his short invasion of France, which might be called abortive, if the promise of a sum of money from the king of that country had not given him an exhilarating motive for returning to the arms of his mistresses. To the list of his crimes he added the unjust prosecution of his own brother, the duke of Clarence, whom he had the ingratitude to accuse in person before the House of Peers, and the barbarity to consent to his execution, but not without some regard to the taste of that prince, who being allowed to choose the mode of his death, preferred being drowned in a butt of Malmsey wine!

The remainder of Edward's days presents a wretched picture of depravity and weakness, pompous threatenings against the French monarch, and insignificant performances. He was on the eve of apparently real preparations for a serious attack on Lewis, when he was seized with a disease which terminated his reign in the 42d year of his age. The elder of Edward's two sons, a boy in his thirteenth year, was declared his successor, by the title of

Edward V. A. D. 1483;—but the duke of Gloucester, the late king's brother, was named Protector of the kingdom during the minority. Never was trust more fatally bestowed. That ambitious and blood-thirsty miscreant now instituted a system of the most flagitious villainy ever exhibited among mankind. He fomented the rising dissensions of the old nobility, who had taken umbrage at the queen's additions to the peerage, while, at the same time, by professions of attachment, he won her confidence. Then he gained over the duke of Buckingham and some other lords to aid his scheme of obtaining the guardianship and custody of the young king. Having accomplished this, he next got possession of the king's brother, and, under pretence of preserving them from danger, had them conveyed to the tower. It was now his interest to spread a report of their illegitimacy, and by various means to defer the intended coronation of Edward. But these measures, unprincipled and dishonourable as they were, wrought too slowly for his desires, and too softly for his ferocity. It became expedient to get rid of those persons whose characters and attachment to the royal family pointed them out as obstacles in the way of his ambition. The blood of several noblemen, accordingly, was shed without compunction, and without justifiable cause. He now grew weary of the mask which he had worn for some time, and, after sundry artifices, succeeded in producing something like an appearance of popular election to the throne, which he affected to be equally unable and unwilling to fill.

Civil history.

Richard III. A. D. 1483.—His first act, after this elevation, was calculated to remove two at least of the rising evils which threatened its security. These were the princes in the tower, whom he procured to be smothered to death and privately buried. Thinking himself now tolerably safe at home, he began to form some foreign alliances, in order to confirm his power; and, by concessions to the clergy, and liberality to his friends, seems to have expected that he should identify his continuance in the government with the interests of those who were able in any degree to promote it.

But danger, as is usual, arose in a quarter to which his attention had been little directed, or which, in the pride of power, he had only beheld to ridicule. Henry, earl of Richmond, the only surviving branch of the house of Lancaster, had long lived an exile, and in all probability without a ray of hope of the prosperity that awaited him. With this prince did Buckingham, now disliked and suspected by Richard, enter into negociations for recovering the throne of his ancestors. That nobleman himself, betrayed before his plot was fully ripe, was not permitted to witness the success of his associate. Henry, soon afterwards landing in England, was obliged to return to Brittany, on hearing of his capture. This induced Richard to take measures for his own safety, quite of a piece with his former practices, but indicative of a pliancy and insinuation of manners of which it would have been thought his savageness was incapable. One proof of this was his overcoming the horror and well founded dislike of the Lady Anne, widow of the young prince of Wales, whom his own hands had murdered at Tewkesbury, and actually persuading her to become his wife!

The earl of Richmond, once more making a descent on England, asserted his claims to the crown. Richard, whose only virtue was courage, hastened to meet him. The respective armies encountered at Bosworth-field, where, after a display of the most determined valour on both sides, fortune declared in favour of Henry, by the fall of his opponent and a decisive victory. The crown which Richard had worn, being found among the slain, was immediately placed on the head of the victor, whom the soldiers now proclaimed king. Thus ended the murderous conflict of the rival houses of York and Lancaster, by the success of Henry.

Henry VII. A. D. 1485, who, by his marriage with Elizabeth, daughter of Edward IV. fortunately united the rights of both families. This itself, and still more certainly in connection with his recent services to the country in freeing it from an odious tyrant, would have proved a sufficient recommendation to the throne. But the jealous temper of Henry, who always disliked the house of York, prompted him to defer the coronation of that princess for two years, by which means he seems to have expected that the priority of his own title would be generally and substantially admitted. The policy of such delay, nevertheless, was very questionable. His reasons for it were so obvious, and his conduct to that princess so ungenerous, as rather to enhance than conciliate the doubts which existed in men's minds, and in all probability gave occasion to those demurrings and appearances of disaffection which so frequently disquieted his reign. Yet the government of this prince, despotic, cold-hearted, severe, and avaricious as he was, proved of singular utility to his country. He had the sagacity, not indeed very marvellous, to discover that the welfare of the people was intimately connected with his own prosperity. His selfishness, therefore, more perhaps than his benevolence, of which there was no mighty portion in his character, suggested many salutary laws for the preservation of a good police; and a similar principle gave rise to several enactments for the promotion of commerce, which, though less commendable from their partaking of the errors in the prevalent theories, or, to use a more appropriate expression, vague notions of political economy of the times, were at least immediately instrumental in augmenting the revenues of the country. In depressing the power of the nobles, which he did very effectually, he was more actuated by the natural propensity to be uncontrolled, than the liberal idea of relieving the community from their grievous pretensions; but it might well be questioned, whether his own arbitrary rule, the imposition of several heavy taxes, and his participation in the profits of some unjustifiable exactions, did not prove more odious and revolting to popular feeling, than all the injurious but not uncourtly bonds of the feudal authority. He maintained peace with foreign powers, more from a personal unwillingness to diminish the contents of his treasury, than a conviction of the general unprofitableness and inexpediency of war; but his caution or parsimony, in this respect, was friendly to the exhausted energies of the kingdom, which could ill have borne the expences of a large military establishment, and the unsatiableness of his own avarice. In a word, the patriotic historian of England, in contemplating the period of the seventh Henry, is much more likely to be impressed with a sense of gratitude for the soundness of constitution which could recover his country from its previous convulsions, and preserve it under its subsequent severity of regimen, than to be animated by any sentiment of admiration or esteem for the individual to whose vigorous and unfeeling governance it was committed. The principal events of this reign may be briefly stated.

An insurrection under some of the leaders of the York faction was speedily subdued by a general offer of pardon, and an accumulation of much more power than what was necessary to quell it. To this succeeded a most daring and improbable imposition, but contrived to keep alive the uneasiness of the king,—the substitution of one Lambert Simnel, a baker's boy, for the Earl of Warwick, son of the duke of Clarence, put to death in a former reign, as already mentioned, whom Richard had confined to the tower, where he now lodged. No small degree of address and activity was required to defeat the consequence of this device, which led to an obstinate battle at Stoke in Nottinghamshire, where the king's forces were decisively victorious. Poor Simnel himself was taken prisoner, and instead of filling a throne, as his adherents anticipated, was content to become one of the meanest appendages on royalty—that of scullion in the king's kitchen! A few years afterwards appeared another impostor in the person of Perkin Warbeck, whose ingenuity and multifarious adventures surpassed the simple narrative of his predecessor. This youth being induced by the old duchess of Burgundy, the implacable opponent of Henry, to personate the duke of York lately murdered in the tower with his brother Edward, was recognised by many of the nobles, and a great part of the people, as the rightful heir of the throne. The delusion spread far and wide, and threatened a general revolt. But the prudence and policy of the king ultimately defeated the malice and audacity of his enemies. Perkin, condemned to perpetual imprisonment, again meditated insurrection, and was put to death; but not before he had drawn the unfortunate Warwick, whose harmlessness and ignorance might have exempted him from the application of "the tyrant's plea," into a snare, which terminated in his conviction of high-treason, and the loss of his head.

This unmerciful treatment of the last and virtually innocent male descendant of the Plantagenet race, caused great discontent among the people, already abundantly disposed to take umbrage at his government. The marriage of prince Arthur, the king's eldest son, and a great favourite of the nation, with the infanta Catharine of Spain, which soon followed, gave a little relaxation to their murmurs. But the speedy death of that prince was a source of deep regret. His widow was shortly afterwards espoused to the second son, Henry, now made prince of Wales, but who reluctantly submitted to his father's will, in entering upon an espousal which it required the pope's dispensation to solemnize.

The remainder of Henry's reign presents, among some unimportant incidents, the continuance or rather aggravation of the public burdens, and the consequent disaffections, fruitless as they were, of the people, and the arrival of the king of Castile in England, whom Henry received with great magnificence, and from whom he obtained the surrender of the earl of Suffolk, one of his refractory subjects, then under the protection of that monarch. Some thoughts of extending his foreign alliances by marriage employed the mind of Henry, when the approach of death filled him with very different and far less agreeable contemplations. Remorse, terror, the struggles of conscience with avarice and pride, and some very futile efforts to purchase peace of mind by bestowing charity and endowing religious houses, sadly diversified his last sufferings. He died at his favourite residence at Richmond, in the 52d year of his age.

Henry VIII. A. D. 1509. The joy testified at the accession of this prince, was compounded pretty equally of thankfulness for relief from the iron rod of his father, and the pleasing expectation of better times under his promising auspices. Nature had been bountiful to his exterior,—a dispensation which never fails to produce an agreeable impression; and the care which had been bestowed on his education, and which was far from being belied by his attainments or his temper, gave ground for anticipating at least a gracious and a liberal, if not a wise and a prosperous reign. Some of his earliest measures ratified the public opinion, but were rather more manifestly directed to acquire it than can be commended by a rigid moralist. A rupture with France revived the foolish notion of subduing that kingdom, which had formerly deluded and impoverished the nation; but it disclosed the frivolity and puny cast of Henry's mind, and ended in a truce which afforded him a more congenial season for the developement and indulgence of his rising follies. A war with Scotland, which afterwards took place, was more glorious to his arms,—the earl of Surrey gaining a complete and decisive victory over the king of that country, who fell with the chief of his nobility on the bloody field of Flodden. But this success only encouraged him to prosecute a system of unprofitable enterprises and ruinous expenditure. The treasure which his father had left was now dissipated, and some ingenuity was needed to supply its place. Here he had the very adequate assistance of his chief adviser, Cardinal Wolsey, a man who, from very insignificant beginnings, advanced to the highest honours of the state, and the possession of more wealth and influence than had ever before been realized by an English subject. The particulars of his rise, eventful predominance, and degradation, which so much diversify, but at the same time render disgusting, the reign of Henry, will be elsewhere given.

The financial operations of this crafty minister gave great offence to all classes of the community, and, in short, had the effect of converting the government of his master into a hateful despotism. A spirit of insurrection manifested itself, which the most prompt exertions, and some nominal rather than real concessions, at last allayed. This a little abated the sway of the cardinal over the king, but, at the same time, exercised his cunning. Even this, however, acute and venturous as it was, failed to guide him through the difficulties which royal passion occasioned, and which ultimately accomplished his ruin. To the same cause must, in a great degree, be ascribed another revolution which now commenced, and which was much more important and more singular than the subversion and overthrow of a favourite.

After a marriage of eighteen years with Catharine, his brother's widow, who had in that time borne him three children, and whom he continued publicly to respect, though he made no scruple of conjoining a multitude of mistresses in his affections, Henry became enamoured of a young lady of extraordinary beauty, but of such virtuous principles as effectually resisted all his solicitations to illicit enjoyment. There remained nothing for a monarch whose licentiousness had experienced no controul, and could brook no disappointment, but a divorce from his wife, which might enable him to gratify his love by sharing his crown with the object that inspired it. His scrupulous conscience, now no longer at rest in a connection which had always been viewed as approaching to incest, if not actually its completion, and which many reasons had already urged him to break off, was now unburthened to his confessor, the bishop of Lincoln, and afterwards made patent to all the bishops in the kingdom. These, with one exception, declared the marriage unlawful, an opinion which Wolsey himself was not backward to affirm. Application to the pope for a divorce followed in due order, and was promised to be favourably answered. But the necessity which the pontiff happened soon to be under of conciliating the emperor Charles V. the nephew of Catharine, subsequently impeded the dispensation promised. Various contrivances were accordingly employed to divert the English king from his purpose, but without effect. The evasions and dilatoriness of the pope were met, on the part of Henry, with a good deal of positiveness, many arguments drawn from scripture, and even something like a threatening of separation from his ecclesiastical dominion, in the event of refusal. The crisis exceeded the politics of Wolsey, who was no less perplexed than the pope between the contending interests by which he was assailed, and whose trivial and unmanly temporising found at last a vindictive censor in his royal master. By the advice of archbishop Cranmer, who now acquired the king's confidence, and whose attachment to the opinions of Martin Luther, which at this time effected such mighty changes, was already well known, the case of the wished-for divorce was submitted to the judgment of all the learned universities of Europe. On their general concurrence as to its illegality, the marriage was annulled by the same prelate, and shortly afterwards the repudiated queen gave place to the exalted Anne Boleyn. The pope, not yet fully aware, perhaps, of the consequences of his wavering conduct, condemned the sentence of Cranmer. But the king had gone too far to retract, and, willing enough, it seems, to shake off the trammels of Rome, proclaimed himself head of the church of England. Parliament concurred in his resolution, ratified his newly assumed title, and abolished the papal authority throughout the kingdom. The bulk of the people, who had been gradually prepared for such a revolution, joyfully beheld these measures, and the subsequent demolition of monasteries, and other ecclesiastical establishments, by which an immense revenue accrued to the crown.

But though the king had thus abandoned the controul of Rome, he had not in any measure relinquished the creed of the church, or espoused the sentiments of the reformation. It is probable that he still chose to flatter himself with the title of Defender of the Faith, which had been some time before conferred on him by the pope, in testimony of satisfaction at the support he had given to the Romish doctrines, by the publication of a work maintaining the seven sacraments against the opinions of Luther. Nothing could be more inconsistent and unreasonable than the conduct which he now displayed in matters of a religious nature, or more harassing to such of his subjects as were conscientiously attached to either of the rival systems which claimed their devout regard. No wonder, then, that, among the events of this period, so decidedly affected by the violence and despotic behaviour of the monarch, we are struck with the martyrdom of persons holding very different religious persuasions. The motley character of Henry's court was a fit sample of the discordant opinions which prevailed among the people. The queen was an advocate for the new doctrines; Cromwell, the able and faithful servant of Wolsey, now in the king's confidence, had embraced the same views, which he cautiously but powerfully promoted by his various and extensive influence. The archbishop of Canterbury, also high in favour, was no less warmly attached to this cause. On the other hand, the duke of Norfolk, who had great authority in the council, and Gardiner, bishop of Winchester, an artful and insinuating man, were firm adherents to the old system. Among those who suffered about this time were Bainham and Bilney, who had favoured the doctrines of Luther, and Fisher, bishop of Rochester, and the illustrious Sir Thomas More, neither of whom could be induced to acknowledge the king's supremacy. The destruction of the queen herself, which soon afterwards occurred, is in part imputable to the enmity which her heretical sentiments excited in the disciples of the Romish church. But its more ostensible cause was, her having the double misfortune of surviving the passionate fondness of the king, and her innocently incurring the suspicion that her affections were otherwise directed. Nothing could be more inhuman and detestable than the treatment which she received from this libidinous and tyrannical sensualist. The very next day after the execution of Anne Boleyn, the unfeeling and profligate Henry married the Lady Jane Seymour, who had now engaged his capricious fancy,—an excess of brutal and unmitigable appetite, which may be well allowed as an ample apology, were there no other defence, in behalf of that murdered beauty. It is impossible to relate this transaction, without, at the same time, holding up to contempt the language and the proceedings of the parliament which sanctioned such infamous behaviour. The speaker become perfectly eloquent on so fair a subject as the royal graces and accomplishments, compared his majesty to Solomon, to Sampson, and to Absalom, for the respective virtues in which they excelled; and the parliament, in addition to other proofs of base subserviency, ratified the divorce from Anne Boleyn, whose issue, as well as that of the former queen, they declared illegitimate, assigning as a reason why they annulled the marriage, " for that his highness had chosen to wife the excellent and virtuous Lady Jane, who, for her convenient years, excellent beauty, and pureness of flesh and blood, would be apt, God willing, to conceive issue by his highness."

The various innovations and barbarities which Henry practised, naturally produced murmurs and insurrections among the people. But the former were disregarded, and the latter were readily subdued. The king, in reality, had acquired a power and an agency over the minds of the chief nobility and leading characters, by his distribution of the treasures obtained from the dissolution of monasteries, &c. which set him quite above any serious apprehensions of discontent and tumult in the lower ranks of life, aided, as they sometimes were, by several persons of more exalted stations. On these latter he never failed to inflict a vengeance which no intreaty could mitigate, and scarcely any event, however joyful or melancholy, so much as retard. Thus, the birth of a son, afterwards Edward VI. and the death of the queen, two days after delivery, made but a short pause in the summary treatment of those who, in any measure, rebelled against his authority.

Henry remained a widower above two years after her decease, but not without repeated endeavours to obtain a proper successor. This period, indeed, appears to have found him very sufficient employment in the numerous trials and executions which called forth his theological talents and zeal, and by which he thought to promote religious unanimity and concord among his subjects. Alas! the fire and faggot are miserable substitutes for virtuous behaviour and a kind conciliatory disposition, which alone can recommend a practical system to the esteem of mankind. But of this truth neither the king, nor the gerality of those under him, who swayed the affairs of these and subsequent times, entertained any beneficial conviction. It is easier by far to burn a man for his opinions than rationally disprove them, or shew their inferiority by greater purity of character, and more benevolence and self-denial, than they are capable of producing. The case of one Nicolson, or Lambert, is among the most remarkable exhibited in the dismal catalogue of Henry's attempts at conversion. This person, a schoolmaster in London, entertaining and promulgating an opinion not in unison with the established doctrine, concerning the real presence in the bread and wine of the Lord's supper, was cited before the prelates Cranmer and Latimer, themselves adherents in part to the system of Luther, and by them endeavoured to be brought over to the standard of orthodoxy. But, instead of yielding to their reasonings and advice, he chose to appeal to the king. Henry, vain of his polemical prowess, was not displeased to be favoured with such an opportunity of displaying his learning and logic. All this had been very well, if a determination by any and all means to get the better in the disputation had not prompted him to employ a sort of argument in which he was sure to excel any controvertist in the kingdom. Public notice was given of his royal intention to enter the lists with the schoolmaster; and suitable accommodations were made in Westminster-hall for the purpose. What preparation in the way of study the king underwent does not appear; but it is certain, that on the day appointed he came sufficiently apparelled and accompanied to convince any man in his sober senses, that it would be highly hazardous to dispute with him. Poor Lambert, without a single individual to espouse his cause, or instruct him how to act on so trying an occasion, was called on, in face of royalty, supported by all the prelates, peers, judges, and lawyers of the land, to defend his opinions against the arguments by which they were condemned, or to abandon them, on pain of incurring the vengeance of the law. After some compliments, with which the schoolmaster thought proper to preface his reply, and which were indignantly spurned, the king urged a few arguments against his opponent. These were enthusiastically applauded by the audience, who had already decided the question in favour of royalty. A succession of bishops following up the blow, which had itself proved efficacious enough to astonish the delinquent, poured in such proofs and rhetoric as left him absolutely stupified, mute, and motionless. He was far, however, from being convinced; and, summoning up courage, when the king proposed to him the question, "Whether he would recant his errors or die for his obstinacy?" answered, that he cast himself entirely on his majesty's clemency; and on the reply being made to this, that his majesty "would never protect a heretic," which was followed by reading the sentence of condemnation, prepared, with unshaken fortitude, to encounter the shocking sufferings and horrible death now decreed against him. This victory was so flattering to the king, and gave such strength to all the other arguments by which his creed was defended, that he appears henceforth to have resolved more vigorously than ever to punish the infatuated creatures who could presume to differ in opinion from him.

In the midst of the diabolical barbarities which testified the intolerance of the times, Henry determined to take another wife. The lady now pointed out as quite suitable to his taste, and eligible from her German connections, was Anne of Cleves. In this personage, however, notwithstanding her size, which was large enough to match well with his own immensity of carcase, he was grievously disappointed, though, for reasons of state, he was obliged to marry her. His disgust increased on farther acquaintance; and Cromwell, who had recommended the match, afterwards struggled very unsuccessfully with his altered regard, which at last vented itself in signing the death-warrant of that favourite. From the new queen, Henry speedily obtained a divorce on very curious grounds. But the parliament, as usual, was quite agreeable to his wishes; and the lady herself, an example of uncommon moderation and insensibility, perhaps also moved by very politic reasons, perfectly and heartily concurred in the separation. He was now at liberty to seek another partner, whom he speedily found in the person of Catharine Howard, niece to the duke of Norfolk. This connection gave just cause for apprehension to the protestants, at least for sometime, her family and friends being zealously attached to the Romish faith. But the king's joy in this marriage, which had every appearance of sincerity, did not continue long. An unexpected accusation of her infidelity to the marriage-bed, resting on very alarming evidence, and a just conviction, at all events, of her previous incontinency, roused the indignation and wounded the pride of the king. Sentence of death, his usual remedy, followed, and left him again a widower. After this lamentable exposure, a most extraordinary act was passed, in which, among other things, it was declared high-treason for any woman, not a virgin, but supposed such, to marry the king. It resulted from this absurd decree, that any frail maid, who had the misfortune to be courted by him, was reduced to the painful necessity of either disclosing her shame, and so ruining her fortune, or incurring the risk of her head by hazarding a discovery after marriage. This monstrous clause occasioned no small merriment among the people, who said, wisely enough, that the king must henceforth look out for a widow, as no reputed maid would ever be induced to incur the penalty of the law. It is a little singular, that Henry appears actually to have proceeded on this suggestion, by taking, for his sixth and last wife, Catharine Parr, widow of the late Lord Latimer, who had the good fortune to survive him, but not without incurring his displeasure, by a pertinacity in disputation on theological subjects, which at one time had like to have exposed her to the awful hazards of impeachment.

The latter days of Henry were marked by no relenting condescensions or gleams of benevolence, which could soften down the memory of his former cruelties. Rendered odious by an unwieldy and bloated body, a morose and gloomy air, and become irascible by infirmities and disease, he seems to have revenged himself for the disgust and uneasiness which he occasioned, by the savage delight of shedding blood, and that too, sometimes, of those whose services had merited reward, or whose age and sex ought to have called forth mercy, as if, by exciting terror, he could produce respect, and as if he imagined that his attendants, escaping the severity of his wrath, would be prompted by gratitude to entertain affection. The whole weight of his iniquity, indeed, ought not to be charged on himself. A nobility that could crouch to such a monster, and a parliament that, affecting to represent the mind and feeling of the nation, could vilely mould itself into the pander for his lusts, and the approver of his murders, were implicated to the full amount of their tolerance and depravity in the guilt and misery of his reign. But it has been noticed among the singularities of their history, that, while the English have generally proved abundantly submissive to their tyrants and oppressors, they have shewn themselves insolent enough and ungrateful towards those princes whose mildness and virtues ought to have nherited their love and esteem. Henry's health rapidly declined; but his courtiers, afraid of his violence, which became more and more outrageous as he approached his end, durst not inform him of his dying condition. At last one of them ventured to communicate to him the impression which his appearance excited, and to exhort him to prepare for the final change which was so near at hand. The king expressed his resignation, and desired to see Cranmer, but became speechless before that prelate arrived. He died in the 56th year of his age.

Edward VI. A. D. 1547.—The vanity of Henry projected a continuance of his authority after death. For this purpose he imposed various regulations, and appointed a council of sixteen persons, by which the concerns of the government were to be carried on during the minority of his son, now only nine years old, but whose majority, by a clause also in his will, he had fixed at the completion of his eighteenth year. But the first act of the executors, now no longer in dread, was calculated to defeat his aim.

They chose the earl of Hertford, afterwards duke of Somerset, uncle to the young prince, protector of the realm; lodged the regal power in him, and granted him the privilege of nominating his own privy council. The only opposer of this important measure was the lord chancellor Wriothesley, a man of an ambitious and haughty mind, who discovered in it the establishment of an authority that would materially interfere with his own views.

The protector merited the confidence thus reposed in him; and being strongly inclined to the new religion, which he could now with some degree of safety profess, declared his intention of rectifying the abuses of the old system,—a symptom which the protestants hailed as promise of the most beneficial changes. A great share of popularity was the natural consequence of his conciliatory and courteous behaviour; and the advice of Cranmer, to which he had recourse in all matters concerning religion, at that period the most interesting topic in political economy, gave a satisfaction, which was no less the result of affection for that distinguished prelate, than a conviction of its substantial wisdom. There were not wanting some persons, indeed, who anticipated and wished a much more radical revolution in religion than what Cranmer projected or advised. To them, in the fervour and brilliancy of evidence with which the new doctrines had taken possession both of their judgments and feelings, it appeared superfluous, if not profane, to prescribe any ritual for devotion, or to attempt the guidance and confinement of the imagination by visible emblems and bodily observances; nor, in their spiritual conceptions, did either the temporal power or the gorgeous appendages of a costly establishment comport with the early history, the celestial, not worldly pretensions, and the transcendental efficacy of revelation. But Cranmer, contemplating, no doubt, the characters and tastes of the bulk of mankind, who are more influenced by fashion than by reason, and to whom the existence and the claims of abstract truth are as mere nonentities, unknown and disregarded, appears to have meditated an institution, which, while it never could shock the understanding of the intelligent, might present every requisite assistance to the weakness of piety, and even by furnishing an innocent gratification to the senses, operate as at least an occasional substitute for the allurements of vice. His object, therefore, was to reform, not to subvert,—to apply, with a discriminating judgment, the pruning knife to the venerable, but rank vine, which shed a baneful gloom over the land,—not with one rash thrust of the plough to level it with the refuse of the dunghill; and it is now for the voice of candour, at the distance of two centuries and a half, to declare, whether any national establishment of religion has yielded fairer and more abundant fruit, or conjoins more enlightened doctrine with greater dignity of character and wider capabilities of utility and comfort.

The chief opponent to the graduated reformation thus projected, was Gardiner, bishop of Winchester, whose conduct excited the indignation of the council, by whom he was at last committed to the Fleet. Bonner, bishop of London, received a like sentence, but was less tenacious of his opinions; and Tonstal, bishop of Durham, who objected to the new regulations, was dismissed the council. Some delay occurred in accomplishing the change, in consequence of a rupture with Scotland, which required the personal exertions of the protector in that kingdom. These were eminently successful in a decisive victory on the field of Pinkey, near Musselburgh. This expedition procured popular applause for the protector, but rather raised the envy of several of the nobility, some demonstrations of which, together with the insidious practices of his own brother, Lord Thomas Seymour, a turbulent and artful man, compelled him to return home, before he had reaped all the advantages likely to accrue from it. This nobleman, whose talents were supposed superior to his brother's, had, by his address and insinuation, attracted the regards of the queen-dowager and obtained her hand,—a connection which increased his influence, and rendered him still more formidable to the protector. Not satisfied with a new patent for admiral, and an additional appointment, he induced the young king to apply to parliament to nominate him his governor, and, in a multitude of ways, contrived to engage the principal nobility on his side, and thus disturbed the peace of the government. The menaces of the council scarcely restrained his pertinacity and caballing; and even the death of his spouse, so far from repressing his ambition, afforded him rather a new incitement, by raising his hopes of gaining the affections of the princess Elizabeth, afterwards queen, to whom he now made his addresses. That lady seems to have listened to him with a favourable ear. But as her father, the late king, had excluded his daughters from the succession in the event of their marrying without the consent of the executors, which it was unlikely, if not impossible, that Seymour should obtain, it was presumed that he aimed at regal authority by means of the highest injustice and atrocity. The protector, fully aware of the dangerous machinations of his brother, endeavoured, by a variety of expedients, to defeat or prevent his projects. On their failure, he was persuaded by Dudley, earl of Warwick, a wicked and artful man, who, at this time, was plotting his own rise by the ruin of the two brothers, to employ against him the extent of the authority with which he was invested. At his suggestion, Seymour was sent to the Tower; a bill of attainder was afterwards preferred against him; and on the concurrence of parliament, without any formal trial, the sentence of death was put in execution. This severity was very disagreeable to the nation, and brought the protector under no small odium. He recovered his popularity in great degree by endeavouring to relieve the distresses of the community, which had arisen from various causes, and at last broke out into insurrection. But the augmenting influence of Warwick now threatened his destruction, by forming a party in the council, resolute on freeing themselves from his controul. In reality, he had excited the envy and hatred of the nobility in general by his superior magnificence and power, and his efforts in favour of the popular interest. Every opportunity was accordingly taken to expose his errors, and hold him up as the author of the public calamities. Warwick, assuming consequence as he saw his plans ripening into effect, witnessed the accumulating difficulties of the protector with pleasure, as the harbingers of his own elevation, and, from one step to another, at last arrived at supremacy of power. The protector, arraigned on sundry charges, not exactly amounting to high treason, for a time eluded the blow which was aimed at him, by a humble confession before the council. He was deprived, indeed, of his offices, and a heavy fine was imposed on his estate. But this was remitted by the kindness of the king, and he shortly afterwards was re-admitted to the council. His fate, however, fast hastened, very greatly owing to his own imprudence in throwing out invectives against his enemy, now created duke of Northumberland. A project for murdering that nobleman, in which he engaged, was discovered, and formed one of the articles by which he was again impeached. This crime had been made felony in the reign of Henry VII. and Somerset was accordingly condemned. His execution was peculiarly distressing to the people, by whom, notwithstanding sundry faults, which, if not of a very aggravated nature, are apt to be forgotten on such occasions, he had always been regarded with kindness. Many rushed in to obtain some of his blood on their handkerchiefs as a precious relic; and which some afterwards upbraidingly displayed in the eyes of Northumberland, when about to suffer a similar death.

The infirm condition of the king's health advanced the ambitious views of that nobleman. Contemplating, if not in reality, as has been suspected, meditating the death of Edward, whose constitution appears to have been naturally delicate, he laboured to alter the succession to the crown, to the prejudice of the two sisters Mary and Elizabeth, and the Queen of Scots, in favour of the Marchioness of Dorset, or rather her next heir the Lady Jane Grey, to whom he had married his fourth son, the Lord Guilford Dudley. The king, persuaded by his reasonings, at last gave consent to the projected arrangement, and directed the judges to draw up letters-patent for the purpose. Their demurs and objections were submitted to the council, and finally overcome by the king's granting pardon for what they should draw up, when the measure was completed. After this the king grew gradually worse, and his physicians having been dismissed by Northumberland's advice, he was put under the care of a female empiric, by whose treatment his complaints were so much aggravated as to assume an alarming aspect. He died at Greenwich in the sixteenth year of his age, regretted by the people, who had flattered themselves that his amiable and virtuous character would secure a happy reign.

Mary, A. D. 1553.—This princess was in the country when her brother died, which gave Northumberland an opportunity to put in force the deed alluded to, by proclaiming the lady Jane Grey queen of England, an honour which she reluctantly received, and which she possessed for no longer a period than ten days. Mary having written to the council demanding her right, received an insolent answer, informing her that she had been declared illegitimate by parliament, and had consequently no title to the throne. This reply was undoubtedly instigated by Northumberland, to whom the council was in some measure under the necessity of at least feigning compliance. But the pretensions of this princess were so obviously superior to those of Lady Jane Grey, that she soon found herself at the head of a party sufficiently powerful to contend in her behalf, with the highest probability of success, whilst to her rival, if one so unassuming and reluctant merit the name, all the efforts of her most anxious advocates could procure only a few adherents, and scarcely any audible expression of allegiance, except from those who had no power or will of their own. Whenever an opportunity was allowed, by the departure of Northumberland to head the troops which he had levied, the council declared against him, and their voice was almost instantly joined by the mayor, aldermen, and city of London. Mary's claims were now irresistible, being supported by 40,000 men, whereas Northumberland had but a handful, and even these far from being confirmed in their resistance. Lady Jane herself, perceiving the total failure of her cause, retired with her mother to a private life. Nor was it long before that nobleman, ensnared in his own toils, and utterly deserted when on the brink of ruin, attempted, by the meanest dissimulation, to commend himself to the very person whom it had been his most manifest solicitude to defraud and oppose. But this base duplicity did not succeed. He was arrested, committed to the tower, tried, and executed. There suffered with him only two persons,—certainly an instance of moderation in punishing so high an offence. Sentence, indeed, was also passed on Lady Jane and her husband; but apparently there existed no intention on the part of Mary to put them to death, till the imprudence of that unfortunate woman's father, the duke of Suffolk, in taking an active part in a rebellion, drew down the fatal vengeance of the queen. Of their innocence it is almost as impossible to doubt, as it is to deny that their tender years, and the temptation and influence to which they were exposed, ought to have pleaded effectually for their pardon. But, alas! theirs was by no means the only blood shed in this calamitous and soul-appalling reign, in defiance of all the claims of humanity, mercy, and truth.

The ardent attachment of Mary to the Catholic faith was long and universally known,—a circumstance which occasioned no small uneasiness to the protestants, and readily accounts for the wishes, at least of many, that the succession could have been legally and efficiently secured on another. Some of the earliest espousers of her claims had conditioned for, and actually obtained, her promise for the continuance of religion in the same state in which she found it. But it was their unhappiness to witness the violation of her engagement, and the adoption of a system of coercion and terror, which disregarded justice, and arrogated the prerogative of the Almighty. She resolved by every means, except mercy and gentle persuasion, to bring the people to her own sentiments on religion, and to restore the full influence and despotic authority of the ancient faith. It soon became apparent, notwithstanding her duplicity and prevarication, that she was bent on undoing every thing that had been done by the reformers, and that in place of a toleration, which she still pretended to hold out, the most rigorous appearance of unanimity would be exacted.

The first serious alarm given to the protestants was the harsh treatment of Cranmer, the exemplar and bulwark of their cause. Having repelled an aspersion that he meant, in compliment to majesty, to officiate in the Latin service, he incurred the resentment of the queen, who had him cast into prison, tried, and convicted of high-treason, for formerly concurring with the council in favour of Lady Jane Grey, though the sentence was not then executed, as she appears to have meditated for him a more awful death. Shortly after this step and some other indications of her bigotry, many foreigners who were attached to the reformation, thought proper to leave a country which they perceived to be threatened with persecution. Their foresight was confirmed by an act of parliament, which, following up the queen's intentions, repealed all the statutes of her predecessor respecting religion, and re-established matters on the same foundation on which they stood at the death of her father.

During these preparatory measures, the ministry were engaged in providing a husband for Mary. The individual on whom they ultimately decided, was Philip of Spain, son of Charles V. whose intolerable spirit, haughty deportment, and unfeeling heart, did ample justice to their notions of congruity. A more detestable couple never wielded an iron rod over a prostrate kingdom. The match was highly disagreeable to the people in general, who anticipated nothing less than that their country would become a mere province of a foreign power. Even many catholics objected to it, and an insurrection, which was headed by a gentleman of that persuasion, bore at one time an alarming aspect. But the protestants had most reason to complain, and soon learned that their fears were not unfounded. Philip, whose fastidious taste nauseated the fulsome fondness, and barely tolerated the disagreeable person of his consort, cordially joined with her in abhorrence of their principles, and a determination to extirpate them. They listened with eagerness to the harsh suggestions of the temporising bishop Gardiner, in opposition to the humane and liberal advice of cardinal Pole, a man whose conscientious regard to the Romish faith, under several aspersions and difficulties, no less demonstrated the firmness of his character, than his good sense and learning reflected light on the age in which he lived. But even Gardiner had the sagacity or cunning to avoid being the visible and busied agent in the work of persecution which now commenced. He found a ready substitute in Bonner, bishop of London, one of those indescribable monsters whom the will of heaven permits occasionally to trample over humanity, as a terrifying sample of the infernal progeny. After a trial of the agency of burning, on Hooper, bishop of Gloucester, and three clergymen of the names of Rogers, Saunders, and Taylor, without the salutary effect of conversion, or the deterring many more from the like offence, he devolved on that furious creature the management of those flames which have so horribly blazoned this period of English history.

Neither amiable feeling nor justifiable curiosity can be gratified by a recital of the atrocities now committed under the semblance of regard to religion, and a tender concern for mens souls. Suffice it to mention, that during a course of three years, in which this mode of reclaiming heretics was practised, the number of those who suffered at the stake amounted to 279. Of these, five were bishops, twenty-one clergymen, eight lay-gentlemen, eighty-four tradesmen, one hundred husbandmen, servants, and labourers, fifty-five women, and four children. Such persecution, in addition to numberless fines and confiscations, besides proving utterly abortive as to the alleged purpose for which it was employed, became so odious to the nation, that the perpetrators and designers were fain to shift the blame from one another, and to screen themselves under various pretences. Nor did the temporal concerns of the kingdom go on more prosperously.

For some time, Mary flattered herself with the prospect of an heir to the crown in direct line; the fortunate event was hastily communicated to foreign courts, and occasioned great rejoicings and many prayers at home; and Philip appears to have artfully kept up the belief, in the hopes of supporting and augmenting his authority, But time at length disclosed the delusion, and the queen's increase of size was found to be owing to a dropsical affection. The mistake, by giving occasion to an improper treatment, accelerated her dissolution. The absence of her husband, on whom she doated, and who had abandoned the kingdom in disgust, was a source of continual fretfulness to her; an unsuccessful war with France mortified her pride in an extreme degree; she was conscious of being hated by her subjects, and could not endure to think that she should be succeeded by her sister Elizabeth, whom she had always disliked, and long wished to find a fit opportunity to destroy. These and other disquieting causes threw her into a fever, which, mercifully for England, terminated her life and short reign in the 43d year of her age.

Elizabeth, A. D. 1558.—This princess came to the throne, not only without opposition, although there were other persons who might claim it, and she herself had been formerly declared illegitimate, but with very general demonstrations of satisfaction. The conduct and character of her predecessor, however calculated to suit the prejudices of some individuals, were pretty universally offensive, and the nation appeared anxious and hopeful for the accession of one who had given many evidences of superior prudence, and whose long discipline in the school of adversity was warrant for the opinion, that she could scarcely be destitute of sympathy for the afflicted. To excellent natural talents, and a sagacious and resolute mind, she had conjoined a large share of learning, almost the only employment in which it was safe for her to engage during the critical times of the former reigns, and the habit of controuling her inclinations and concealing her sentiments, the natural effect of perpetual vigilance among innumerable difficulties, and which, though perhaps not very amiable in private life, is certainly to be esteemed for its rarity and usefulness in a sovereign. She was scarcely proclaimed queen, when Philip, the husband of her late sister, by his ambassador, made her proposals of marriage, to which she returned an obliging but evasive answer. That prince had always professed the highest opinion of Elizabeth, who, again, never could bring herself to acknowledge it, by entertaining a similar impression in his favour, and in whose peculiar constitution or temper, besides, there existed an insuperable aversion to a change of condition, which has never been thoroughly understood. That she was capable of ardent affection for the other sex, is decided by her history; but whether bodily defect, pride of independence, or, which is more probable, a propensity to have many lovers, prevented her from ennobling any individual by the surrender of her hand, is extremely uncertain.

Elizabeth early purposed to reform the church, and, immediately after assuming the reins of government, set about that task, but not without the deliberation and caution which characterised most of her actions. By the advice of sir William Cecil, secretary of state, she recalled the exiles, and liberated those who were imprisoned on account of their religion. She then prohibited preaching without a licence; ordered a great part of the service to be delivered in the native tongue, and forbade the elevation of the host in her presence,—measures altogether indicating a resolution to abandon the established system. Parliament concurred in her views, and in one session the whole form of religion was modelled to the present standard. Some opposition was occasionally given to the successive changes, but it was insignificant; and in proof of the readiness with which they were accomplished, it has been remarked, that out of more than nine thousand beneficed clergymen, only about one hundred and eighty chose to retain their faith by the sacrifice of their preferments.

Such a radical and decisive preference to the protestant cause made all the catholic princes of Europe either the open or the secret enemies of Elizabeth; and Philip himself, perceiving an end of all his hopes with respect to her, made a separate treaty with France, which induced her shortly afterwards to conclude a peace with the same power. She was now without an ally, or any foreign friends who could prove serviceable to her. It behoved her more carefully, therefore, to husband her natural resources, and study to secure the affections of her subjects, by conscientiously and diligently promoting their happiness and prosperity. It is due to the memory of this spirited princess, to declare, that her labours were crowned with success; and that, notwithstanding her despotic principles of government, and disregard to the privileges of parliament, and certain political liberties of the people, England attained most rapidly, under her dominion, to a very exalted pitch of splendour and power. It is certain, in a word, that she was sincerely and actively desirous of the welfare of the kingdom; but it is equally so, that she conceived and wished it rather to emanate from her own authority and wise administration, than to be at all dependent on the natural and healthy functions of a popular constitution. Much of the glory of her reign was owing to her possessing very able ministers, and much of her excellence consisted in a disposition to profit by their sagacity.

But it was the misfortune of Elizabeth, for all things human and all the virtues of man are imperfect, to be defective in that generosity of temper and kindliness of heart which are essential to an amiable character, and which often of themselves, without great talent, lead to commendable, because beneficent conduct. Her interference in the troubles of the sister-kingdom, and her injurious behaviour to her cousin Mary, the beautiful and unfortunate queen of Scots, have left a stain on her memory, which the impartial historian finds it impossible to obliterate. Some of the particulars of the transaction belong to another section,—others may be given here.

The dissensions and animosity which had taken place among the Scots, on the subject of religion, afforded Elizabeth an opportunity of fomenting a faction against that princess, who had incurred her resentment by quartering the arms of England, to which she certainly had well-grounded pretensions, as representative of Margaret, the eldest daughter of Henry VII. married to James IV. king of Scotland. Mary was prompted to this imprudent assumption by her maternal uncles the Guises. But the offence which it gave being more trivial than formidable, would probably have occasioned little thought to Elizabeth, firmly seated on the throne as she was by the decision of parliament and the affections of the people, had not some pretence been necessary to cloak her encouragement of the Scots reformers, who looked up to her for assistance against their natural sovereign, and who were obstinately bent on the destruction of the ancient superstition. Scotland, in reality, was the spot on which the partisans of Mary's claim could be most conveniently assembled, and where, of course, it was safest for Elizabeth to oppose them in the very commencement of their career, and while she had the support and countenance of so energetic a party united against them on a separate plea.

But it must not be imagined, that the personal feelings of Elizabeth alone, or even chiefly, instigated her to the policy which she now adopted. It was the suggestion of her council, and more especially of Cecil, who represented the former, and the eventual mischief to England from an union between France and the sister kingdom, and the dangers which might result from the ambition, and talents, and power of the Guises, engaged on the side of even the doubtful title of their relative. Nothing could be more obvious than the consideration, that the French, once firmly established in Scotland on the ruin of the protestants, would be much more likely to give trouble, though not, perhaps, fatal injury to her kingdom, than when the natural barrier of the ocean still presented a favourite field for the display of English valour. The queen resolved, in spite of her usual economy, to send both a fleet and an army to retrieve the drooping affairs of the Congregation, as the leaders of the Scots reformers had designated themselves; with whom she concluded a treaty of mutual defence, which was to last during the marriage of Mary with Francis, and for a year after; and by which she engaged never to cease her operations till the French were forced out of their country.

The death of Mary of Guise, queen-regent of Scotland, which took place soon after the arrival of Elizabeth's supplies, and before much blood had been shed in the contest, prepared the way for a capitulation; by which it was agreed, that the French should evacuate the kingdom; that the king and queen of France and Scotland should abstain from bearing the arms, or taking the title of England, and that further satisfaction for the injury already done in that respect should be given to Elizabeth; to which were added some concessions in favour of the Scots, including an amnesty for past offences. Elizabeth took care to put one important part of this treaty into execution, by furnishing ships for the removal of the French to their own country. So far, then, her conduct might perhaps seem to be justifiable, at least on those maxims of state-expediency which almost every nation has at one time or other put in practice, in order to guard against a probable or imminent danger. Strict morality, indeed, will rebut the plea of self-defence in this case; because, besides premeditatedly aiding, if not actually exciting sedition, or a rebellious spirit among the subjects of a foreign power, Elizabeth instituted a system of aggression, on the mere surmise, before the receipt of injury, for it is absurd to speak of the heraldic umbrage, and without those formalities which the dignity and awful consequences of national disputes require; nay, which is an aggravation of no ordinary import, in defiance of a conciliatory offer on the part of France, the only power from which she could possibly entertain the slightest apprehensions. But subsequent events, however they were viewed by her jealousy, and however they have been construed by her warmest admirers, will leave no doubt, on the unbiassed mind, of the malignity of her disposition, and the calculating selfishness of her politics.

Mary, the loveliest woman of her time, reared amid the gaieties and gallantry of the most splendid court in Europe, now in the nineteenth year of her age, and already a widow, prepared, not long after the death of her mother, to return to her native country, a striking contrast in almost every thing to the scenes in which her life had been passed, and rendered no way more agreeable to her imagination by recent events, and the general enthusiasm in behalf of a religion always held out to her as a pernicious and damnable heresy. She had hitherto, both during her husband's life and since his death, declined gratifying Elizabeth by acceding to the treaty of Edinburgh, already alluded to, and more especially, through the influence of the same family, refused any formal renunciation of her pretensions, although she had abandoned the visible ensign by which they were supposed to be displayed. Elizabeth, in retaliation, when applied to for a safe conduct, in case she should be obliged to pass through England, on her way to her own kingdom, refused the favour, saying, that till Mary had given satisfaction by ratifying the treaty, she need expect no obligation in return. At this uncourteous denial of a polite but really unimportant request, Mary made no scruple of expressing her indignation, during a very spirited reply to Throgmorton, the English ambassador, by whom it was communicated. Some of her remarks on that occasion shew a perfect understanding of her cousin's character and political views; though she was cautious at the same time to express not only her readiness but her desire to be on good terms with that princess, and not a little commends herself for her moderation, and even good offices, in their intercourse. But a faithful report of this speech, notwithstanding some obliging terms, could not fail to augment the dislike of the imperious and haughty Elizabeth, who had the mean and vindictive cunning to equip a fleet, under the pretence of pursuing pirates, but which was dispatched to take her rival prisoner on the voyage, though without success, in consequence of the occurrence of a fog, which enabled Mary to escape unperceived, and arrive safely in Scotland.

But the snares of the English queen were by no means confined to the sea, or directed to the mere possession of the ill-fated Mary. She took effectual measures for securing the interest and services of those persons on whom it was equally natural, and apparently proper for her unsuspicious cousin to rely, as guides and council in the administration of a precarious and difficult government. This is not the proper place to enumerate the impolitic, if it cannot even be said immoral steps, by which Mary hastened the consummation of her evil fortunes, or to describe the hardships, vicissitudes, indignities, and deprivations, which she experienced, and which at last drew forth as much magnanimity on her part, as they manifested tenderness or humanity on that of her opponents and persecutors. Suffice it to mention, that one calamity followed another, till, to her terrified imagination, there remained no hope but by throwing herself on the power, for it would be mockery to predicate a milder term, of the very individual who had all along studied to accomplish and forward her ruin, though she had latterly professed reconciliation, and affected to interpose on her behalf.

On arriving at Carlisle, Mary wrote a letter to Elizabeth, describing her distressed circumstances, and craving protection. After some deliberation, the queen, whose courtly ministers took care to point out the kind interference of heaven in her behalf, resolved to profit by the event which had thrown so hated a rival into her hands; but, at the same time, to save appearances, and more effectually accomplish all her objects, by some indications of sympathy and friendship, Lord Scrope and Sir Francis Knolles were quickly dispatched with a message of a tender and condoling nature, and also private instructions to watch Mary's motions, and prevent her escape from the kingdom. To a request of a personal interview on the part of Mary, it was replied, that till she had cleared herself of the foul charges with which she had been accused, it would be construed to the dishonour of the queen to shew her public countenance. This galling remark drew tears from Mary, who, however, either from conscious innocence, or a sense of the urgency of her situation, declared, that she would willingly come before the tribunal of her sister on the trial of her guilt. Such a concession was peculiarly desirable to Elizabeth,

Civil history.

as it established her as umpire between Mary and the opposing regent of Scotland, and afforded a pretext for detaining the former till the issue of the inquiry, which, besides, she might readily contrive to defer as long as circumstances required. The earl of Murray, therefore, bastard brother of Mary, who now held that office in the minority of her son, James VI., was immediately directed by Elizabeth to bring forward his accusations; and commissioners, mutually chosen, were appointed to hear both parties. Mary discovered, when it was too late, the danger of the snare into which she had fallen, and endeavoured to evade the proposed trial, as a voluntary diminution of her dignity. But her reluctance increased the solicitude of the queen, whose insinuating and plausible professions at last prevailed.

Into the particulars discussed in the extraordinary conference now held at York, and afterwards in London, it is unnecessary, because it would be unsatisfactory, to enter. The subject of Mary's concern in the murder of her husband Lord Darnley, the chief and only formidable accusation against her, as is well known, is now rather the touchstone of party spirit and personal prejudice, than susceptible of perfect elucidation. Now, on this rock, there is not the slightest intention of committing a *felo de se* in the eyes of any contending reader. Suffice it to say, that, on the one hand, Mary *did* not publicly enter upon her vindication from that foul aspersion; and that, on the other, Elizabeth refused a private interview, which was repeatedly solicited, in order either to manifest her innocence, or to substitute something in its place. Perhaps all the persons engaged in this perplexing and indecisive conference, if such it may be called, acted insincerely, and with respective sinister designs, rather than a conscientious resolution to accomplish the object for which it was ostensibly held. It was at length broken off, certainly on just grounds, by Elizabeth, who at all events effected her purpose of decoying Mary into secure confinement, though she still pretended to negociate with the captive princess, and to regret the occurrence of any difficulties which seemed to prevent an honourable and satisfactory adjustment. Of the importance which was attached to the subsequent safe custody of Mary, an idea may be formed from a letter in the papers of Sir Ralph Sadler, one of the persons to whose vigilance she had for a time been committed. That knight having been found fault with on one occasion, for suffering Mary to accompany him, amidst a host of guards, on a hawking excursion, is at pains to explain the nature of the indulgence, and diminish its hazards. He concludes his statement in rather a peevish, but nevertheless explicit enough manner: "But syns it is not well taken, I wolde to God some other had this charge, that wolde use it with more discretion than I can; for I assure you, I am so wery of it, that, if it were not more for that I would do nothing that shulde offende her Majestie, than for fear of punishment, I wolde come home, and yelde myself to be a prisoner in the Tower all the days of my lif, rather than I wolde attende any longer here upon this charge!" The place in which she was at this period confined was Tutbury in Staffordshire, whither she had been removed from Bolton in Yorkshire, which was thought less appropriate from its being surrounded with catholics.

Civil history.

But neither the artifices nor the prisons of Elizabeth could prevent many of her subjects from feeling interest at least in the fortunes of captive royalty. Her harshness was blamed, because, even admitting the guilt of Mary's conduct, no one could demonstrate the right of the queen to extend punishment to it at her own will, or, in reality, to withhold the opportunity of ascertaining the one and fixing the other. But Elizabeth's reasons for detaining her prisoner received strength by the circumstance of Mary's party in Scotland, availing themselves of the murder of the regent, to assemble in some force, and assume a threatening aspect on the borders of the two countries. Their measures were thwarted, indeed, by her superior means and art; but it was obvious that the presence of their sovereign, rendered more an object of regard than ever by the calamities which she had experienced, might impart a very serious agency to their zeal.

Not more fortunate for Mary was another attempt in her behalf, by one whose motives, as they were more selfish, were the more likely to be unintermitting. This was the duke of Norfolk, the first nobleman in England for rank and influence, and whose qualities and behaviour had procured universal esteem, but on whose susceptible feelings, long attached as they had been to the cause of Mary, her charms and accomplishments raised an emotion inconsistent alike with his safety and previous obligations, and which, besides endangering the object of his ardent affections, ultimately conducted him to the block. After the death of this nobleman, whose very sincerity had hastened his fate, by directing his attention to the laudable nature rather than the portentous consequences of his conduct, Mary was more vigilantly watched than before, but seems never to have abandoned the hope of one day accomplishing her liberty. A plot for this purpose, and her consequent establishment on the throne of England, by the murder of Elizabeth, extensively arranged and powerfully supported, was discovered, and its leaders were justly put to death. Mary, who had undoubtedly so far acquiesced in the scheme as to endeavour by means of it to effect her escape, was now brought to trial as a party in its fabrication and atrocity. After objecting to the competency of the tribunal, she consented to plead in her own behalf, but was refused the aid of counsel and the confronting of the chief witnesses, which the meanest individual in the present times is entitled to demand. Her fate was decreed before an argument had been advanced,—for one of Elizabeth's counsellor's recommended the use of poison rather than incur the odium of a trial; and Mary received sentence of death, which was put into execution at Fotheringay castle, in the 45th year of her age, and the 19th of her residence as a prisoner in England. The queen was hypocrite enough to be solicited and urged by her obsequious parliament, to yield to the event which for ever freed her from the dangerous machinations and bewitching influence of her far more amiable rival.

Elizabeth's uneasiness, affected or real, at the execution of Mary, and any apprehensions she entertained of its effects on the king of Scotland, who at first manifested high indignation at the treatment of his mother, or any other foreign power, were lost in her concern for the issue of the contest with Spain in which she was engaged. Philip, the sovereign of that country, long meditated the destruction of England, against which his resentment was more particularly excited by the encouragement given by it to his revolted subjects in the Netherlands. His preparations were proportioned to his hatred, and issued in an armament, the magnitude and power of which justly awakened the fears and required all the precautionary sagacity and exertions of Elizabeth. Under the word ARMADA, is given an account of the extent and fortune of the portentous equipment which was to execute the vengeance of the Spanish king, but the miserable fate of which still serves as a cordial *memento* in the contemplation of any stupendous threatenings. It was at this period that there arose among the English a race of naval heroes, which has been perpetuated with augmenting lustre to the present times, and in whose chivalrous spirit, intrepid valour, and well-disciplined hardihood, their country never ceases to repose its hope of safety and its love of glory. The names of Raleigh, Howard, Drake, Cavendish, and Hawkins, lead the van in an array which has often decided the fortune of Europe, and always compels the attention of the world.

Elated by her success in vanquishing the designs of Philip, the queen became an assailant in return, and with more effect. The capture of Cadiz, by a fleet and army under the command of the earl of Essex, was a serious mortification to the Spaniards, and on various other occasions they suffered considerable losses. The nobleman now mentioned was among the most eminent of those officers by whose achievements the bravery of the English was crowned. His eminent services had gained the applause of Elizabeth, and his personal qualities had made a deep impression on her heart. The death of the earl of Leicester, her former favourite, left a void, which his various merits were calculated very amply to supply, and certain it is that no one had more effectually obtained the mastery of her affections. His promotion kept pace with his own deserts and her good opinion. It had been well for him if he had known the art of preserving, as well as that of procuring favour. His high-mindedness was greater than was befitting a minion; he forgot the respect due to his sovereign, and exposed himself, by want of caution, to the malignity of his enemies. His failure in subduing a rebellion in Ireland from which he expected an accession of glory, gave them an opportunity of injuring him at home. But even his misfortunes, and their artifices, were in a fair way of being overcome, when his impatience, indiscretion, and criminal ambition hurried him into projects inconsistent with the public peace, and which ended in his ruin. He was tried, condemned, and executed, not without sincere regret, and the most painful irresolution on the part of the queen, who never afterwards was known to enjoy one happy day. A circumstance connected with the death of that unfortunate nobleman, deserves to be recorded, as full of interest, and highly characteristic of Elizabeth in several respects. She had in an early period of their intimacy presented Essex with a ring, and enjoined his sending it to her in any critical conjuncture which might require her friendship and influence in his behalf, as the sight of it would revive her affections, and procure his safety. This ring, then, he actually transmitted, after his condemnation, which accounts for the hopes he continued to entertain of receiving pardon. But the Lady Nottingham, prevailed on by her husband, an enemy of the favourite, whom he employed as his messenger, never delivered the pledge. The queen, indignant at his obstinacy, as she thought, never knew the treachery which had been so fatally practised against him, till the countess, apparently struck with remorse in her last illness, revealed the secret. Its effect was fearful. She shook the dying woman in her bed, cried ' that God might pardon her, but she never would," and resigned herself to the horrors of unalterable despair. The violence of her grief, aggravated probably by a variety of uneasy reflections, and the consciousness that some of her courtiers were already negociating favour with the heir-apparent to the crown, besides the infirmities of age, rapidly brought on fatal symptoms. In this state she was interrogated as to her sentiments respecting a successor, when she distinctly and energetically specified the king of Scotland as alone entitled to that honour. After this she fixed her attention on eternal concerns, sank into a lethargy, and expired without a groan, in the 70th year of her age, and the 45th of a reign, which, notwithstanding all her selfishness, arbitrary proceedings, parsimony, and want of true benevolence, it is impossible not to contemplate without sentiments of admiration, respect, and gratitude.

CHAP. II. HISTORY OF SCOTLAND.

THE Scots, like their southern neighbours, have been anxious to carry back their history to a very early period. Their success in the attempt has been still less obvious and insinuating. Very uncertain legends enumerate a series of kings who existed several ages before the Christian era, and detail with some minuteness the occurrences which characterised them. But they are alike improbable and void of interest,—a sufficient reason why no modern author, however patriotic, has had the hardihood to incorporate them with materials which deserve the title and the meed of authenticity. The earliest accounts of this country, claiming respect, are of Roman growth, not indigenous. When the masters of the world extended their conquests, under Agricola, to this part of the island, they found it inhabited by the Caledonians, of whose origin, manners, and fortunes, it is not now intended to speak. The Romans having repulsed rather than subdued this hardy and valorous people, built a strong wall between the friths of Forth and Clyde, as the boundary of their empire. But the difficulty of maintaining so distant a province, induced Adrian to contract it, by erecting another wall considerably to the south. The possession of the intermediate space was in subsequent times contested by these foreigners and their native opponents, till the necessity of defending their

Civil history.

own vitals, threatened by the Goths and other barbarians, obliged the former to retire to the continent, about the beginning of the fifth century. The Romans amply compensated for the aggressions and occasional severity which they had committed, by communicating some of the elements of civilization, the valuable art of writing, and the use of numbers.

Scots subdue the Picts, A. D. 838.—On their departure, the northern part of Britain was left in the hands of the Scots and Picts,—this last term being used by Bede and other historians as synonymous with Caledonians. The former, who are not mentioned by any Roman writer before the end of the fourth century, were probably a colony of the Celts or Gauls, whom they seem to have resembled in almost every particular of national character. Between these two people, war was carried on for ages, with various success. At last, Kenneth II. called the 69th king of the Scots by fabulous authors, completely vanquished the Picts, and united the whole country, from Adrian's wall to its northern extremity, under one sovereign. From this period the name of the victors, though originally strangers, was applied to the kingdom, and the manners and language of the two people, in all probability never very dissimilar, became inseparably blended. Long before this event, the Christian religion had been introduced into the country, and existed in a purer form than it assumed in the fifth century under the management of Palladius, by whom the Roman Catholic system was established, to the prejudice of the primitive faith. So much for the first of the four periods, into which the judicious Robertson has divided the history of Scotland,—"a region of pure fable and conjecture, (says he) that ought to be totally neglected, or abandoned to the industry and credulity of antiquaries." The second period, according to the same author, reaches from Kenneth's conquest, now mentioned, to the death of Alexander III. In it there is a dawn of light, deserving to be noticed as the commencement of day, and presenting a few objects on which vision may be exercised with some degree of interest. A mere summary of the chief events, therefore, will suffice.

Kings till Gregory, A. D. 883.—Kenneth removed the episcopal see established by the Picts, at Abernethy in Perthshire, to St Andrews. He warred with the Britons. Before and during his reign, the Danes made frequent landings in Scotland. The short reign of his successor, Donald, a feeble and indolent prince, gave advantage to the English, with whom he entered into war. In the following reign of Constantine II. the Danes, under Hobba and Humber, ravaged the country from Fife to the western coast, whence they sailed into Ireland. On their return, they again defeated the Scots under Constantine, who was slain. Grig or Gregory, the next sovereign but one, expelled the Danes, made several successful inroads into England, and one into Ireland, whose king, Duncan, he is said to have made prisoner. The surname of Great has been given to Gregory, which he is thought to have merited by his magnanimity, and, comparatively speaking, splendid deeds.

Kings till Malcolm II. A. D. 1001.—Donald II. or, reckoning the fabulous kings, the sixth, the son of Constantine, had various conflicts with the Danes, who appear about this time to have settled in Moray. He died at Forres of wounds received in battle. His successor, Constantine, nephew of the second prince of that name, formed a very impolitic alliance with the Danes against the English. He was completely defeated by Athelstan, in a battle at Brunanburgh, supposed to be the same as Brugh, and with difficulty escaped. This loss affected him so much, that he retired to a monastery at St Andrews, where he ended his days. Malcolm I. son of Donald, a sagacious and prudent prince, formed an alliance with Edmund of England, from whom he received the principality of Cambria or Cumberland, on doing homage. He lost his life in an expedition to reduce the people of Moray to obedience. Indulph, son of Constantine, who succeeded, repelled a new body of Danes who landed on the shores of Buchan, but perished in the battle. Duff, son of Malcolm, and prince of Cambria, the next king, had a short reign, noticeable for his zeal to reform abuses, which ended in his own ruin. Colin, or Culenus, his successor, was slain in battle against the Britons of Cumberland, who were again vigorously opposed, and their royal family extirpated by the next king, Kenneth, son of Malcolm. This able prince had a severe conflict with the Danes who landed in Argyleshire from Man and some of the neighbouring isles. It was in a battle with that people, in which the Scots were at first thrown into confusion, that a countryman of the name of Hay signalized himself in preventing their flying from the field,—a service for which he was ennobled and had an estate conferred on him. To Kenneth, slain by a traitor, succeeded Constantine, son of Colin,—for, at this period, it will have been observed, each king appears to have been pretty regularly succeeded, not by his own son, but his predecessor's. Now, however, there arose a rival in the person of Malcolm, son of Kenneth, and the country was torn by factions. The former was slain during their contest, in a desperate battle fought on the banks of the Almond water. Grim, son of Duff, was now crowned king, but met with opposition from the same individual, who ultimately accomplished his ambition by ascending the throne. He proved a brave and able prince, but appears to have been too liberal to his retainers in early life, and, as is not unusual, to have become avaricious in his old age. He was successful against the Danes, who had anew invaded Moray and Buchan, where they were almost certain of being favourably received by the descendants of their countrymen.

Malcolm III. A. D. 1057.—Duncan, grandson of Malcolm, succeeded to the throne. He was a mild and gentle prince, and deserved a better fate than he experienced. An insurrection of some of his subjects, aided by a body of Irish, was overcome by the bravery of Macbeth, to whom he gave the command of his army. Then the Danes landed in Fife in great force. After a severe battle with them near Culross, a treaty was proposed, during the adjustment of which, some victuals, impregnated with the juice of the deadly night-shade, were conveyed into the Danish camp. Its effects enabled the Scots to attack them in such a manner that their leader and a few persons were all that escaped. Macbeth, aiming at the crown, did not scruple to murder his sovereign, in order to attain it. The power thus wickedly acquired was used with some judgment, but no less severity. In the end he excited the dislike of the nobility, many of whom fled to Malcolm Canmore, the son of Duncan, then residing in Cumberland. Encouraged by their allegiance, and the assistance of Siward, earl of Northumberland, this prince ventured to attack the usurper, and with complete success. He ascended the throne of his ancestors, in spite of the efforts of Lulac, son of Macbeth.

The history of Scotland becomes somewhat more satisfactory in the reign of this prince. His dominions extended over the whole of what is now called Scotland, in addition to the province of Cumberland, which he continued to hold in feudal tenure. Having espoused the cause of Edgar Etheling, heir of the Saxon race of kings, whose sister Margaret he had married, he provoked a war with William the Conqueror, which was prolonged with various fortune, even after Edgar himself thought proper to acquiesce in the usurpation of that prince. The court of Malcolm formed a place of refuge for the disaffected English; and from them, in all probability, was derived a degree of refinement which compensated for the otherwise prejudicial effects of the embittered contest. William Rufus, after establishing himself in the throne of his fathers, prepared to dispossess Malcolm of the places which he had acquired in Northumberland. But the two monarchs agreed to a peace, which was of short continuance. Malcolm, in order to prevent hostilities, to which his age and devotion disinclined him, paid a visit to the court of his opponent, but being required to do homage, which he conceived inconsistent with his dignity, hastily retired, and commenced aggressions in Northumberland, where he lost his life in an engagement with Mowbray, earl of that county. His son, Edward, fell at the same time. The reign of Malcolm seems to constitute an era in the annals of his country; and his character and fortunes deserve the investigation of some erudite historian.

Kings till David I. A. D. 1124.—The Scots were left in extreme disorder on the death of Malcolm, as his remaining sons were too young to assume the reins of government, and much dissatisfaction had shewn itself among the ancient nobles at the encouragement given to strangers, and the introduction of foreign manners and customs. The crisis was favourable for some daring individual. Donald Bane, brother of Malcolm, usurped the throne, but held it only a few months, the nobles raising up Duncan, natural son of that monarch against him, who soon incurring the hatred of his subjects, was put to death, when Donald again obtained the throne, which he was obliged finally to abandon in favour of Edgar, fourth son of Malcolm, whom the nobles invited from England, where he resided under the protection of his uncle. This prince, who possessed several excellent qualities, maintained peace with the English, to whose good services he had been much indebted, and to whose sovereign, Henry, brother and successor of William Rufus, he gave his sister Matildis, or Maud, in marriage. Edgar was followed by his two brothers in succession. The first of these, Alexander I. is commended for bravery and spirit, whence he got the name of *sharp*, or *the fierce*. He is noted also for his love of justice. He preserved peace with England, and was a benefactor to the church. David I. the other brother, in a shorter reign, accomplished more, and acquired a higher reputation than his predecessor. Even the historian Buchanan, not remarkable for his love of kings, extols him as an honour to his country and to monarchy. His chief political error was excessive love of monasteries, which he multiplied and endowed beyond adequate reasons, and to the prejudice of the best interests of his country. He annexed Northumberland to his crown, but not without a long and severe contest with Stephen, whom he opposed in behalf of his niece, Matilda, the legitimate heir of Henry, as elsewhere related. On the temporary elevation of that princess, David paid her a visit in London; and throughout, his fidelity to her cause and that of her son, Henry, deserves the noblest encomium. The death of his eldest son, also named Henry, was a severe affliction, which it required all his piety to enable him to bear at his advanced period of life. His last measures were judiciously directed to promote the peaceable succession of his grandson, and the comfortable establishment of the other members of his family.

Kings till Alexander III. A. D. 1249.—Malcolm IV. was a minor when he ascended the throne of his grandfather. His reign was troubled by a famine, various insurrections, and a quarrel with the English. By this last he was obliged to surrender Northumberland and Cumberland. He afterwards attended Henry II. into France, as a vassal of that king, which gave great offence to his subjects, some of whom conspired against his life. But he escaped their stratagems, and seemed to be regaining favour by his address and spirit, when he was cut off in the flower of his age. His brother, William, succeeded him, a brave and high-minded prince, who, resolving on the recovery of the English property, was unawares taken prisoner at Alnwick, and thence carried to Henry, at that time in France. He was obliged to do homage to that monarch for his whole kingdom. The Scots, in love to their captive prince, who was a great favourite, consented to the humiliating conditions of his ransom. Richard, the successor of Henry, had the generosity to discharge the obligation, by sending back the noblemen who had been delivered as pledges, and restoring Northumberland to the Scots. This produced a sincere friendship between the two kings, and a peace between their countries, which lasted during the reign of Richard. It was broken for a short time under the vicious government of John, but was renewed on the condition of William's two daughters being given in marriage to the two sons of that sovereign. The remainder of William's time was passed in a state of tranquillity, only a little disturbed by domestic misfortunes, and contributed greatly to the improvement of his subjects in the arts of social life. He died at Stirling, in the 72d year of his age, and the

Civil history. 49th of his reign. Alexander II. succeeded his father when only seventeen years old. He proved an able and valiant prince. The English barons engaged him in their cause against the profligate John, who, however, was for some time successful in ravaging the southern parts of Scotland, which Alexander took good care to retaliate with due animosity. John, by his submission, obtained the protection of the pope, who excommunicated his enemies, and, among the rest, the Scots. A deputation to Rome procured the cessation of this spiritual thunder. The quarrel was renewed with Henry, son and successor of John, but was soon terminated, and peace continued between the countries during the lifetime of these two kings. Alexander repeatedly visited Henry, whose sister he had married, and was always well received. But some jealousies arose on the death of Joan, the Scots queen, and Alexander's subsequent marriage to a foreign lady, which occasioned preparations for war,. though timely mediation prevented bloodshed. Alexander was succeeded by his son, the third of the name, a boy in the ninth year of his age. During the minority of this prince, the family of the Cumins obtained great sway in the government, but were afterwards removed. In this reign the Danes, or Norwegians, landed in great force at Ayr, but were ultimately defeated with dreadful slaughter. Alexander married Margaret, eldest daughter of Henry III. with whom he maintained a good understanding, which was serviceable to both nations. That princess bore him children, whom, as well as herself, he survived. In hopes of a second issue, he married again, but shortly after his union, in going from Burntisland to Kinghorn, was thrown from his horse, and killed in the fall, to the great grief of his subjects, whom he had governed with justice, moderation, and prudence, and who had afterwards to taste the bitter fruits of a contested succession and a civil war. The death of this excellent prince, which took place in 1285, terminates the second period of Dr Robertson's division of Scots history.

The third period of the same author extends to the death of James V. in 1542, containing, therefore, upwards of two centuries and a half, of which he has given a very satisfactory review in his first book, as preliminary to his more copious history of the last period, which again comprehends the time from the date now mentioned, to the accession of James VI. to the crown of England. As that work is universally read, all that is required here is a sketch of the more important events, in the order of time, to preserve continuity and uniformity of design.

Contested succession.—The proper heir of Alexander's crown was Margaret, whom his daughter of the same name bore to the king of Norway. But, at the time of his death, she was an infant and in a foreign country, which occasioned a convention of the estates appointing a regency. On her death, which took place soon after her grandfather's, the right of succession belonged to the descendants of David earl of Huntingdon, third son of king David I. Of these, in particular, were John Baliol grandson of the earl's eldest daughter, and Robert Bruce son of his second daughter. The plea of the former was preferable according to the rules of succession now established; but in those times the order of inheritance was not equally well ascertained, and the prejudices of the people, if not the law of the kingdom, favoured the claim of Bruce. To avoid the miseries of a civil war, the Scots nobility or states hazarded the independence of their country by an appeal to the king of England. Edward profited by the circumstance and the existing anarchy, to state his own pretensions, which, though remote and inconsequential, had the benefit of superior power. He constrained the competitors to acknowledge the sovereignty of the English crown, and having violently taken possession of the kingdom, decided in favour of Baliol, who again professed vassalage, and submitted to every condition imposed on him. But this fealty was of no long duration. Edward's harsh and despotic rule roused the angry feelings and proud spirit of the Scots, and even Baliol himself joined in the rebellion. He was at last obliged to resign the crown, which Edward endeavoured to seize as fallen to the superior lord, when the heroic Wallace animated the resistance of his countrymen. After him arose the grandson of Bruce to vindicate the freedom of Scotland and establish his own right to its throne. His persevering efforts were ultimately prosperous, and the second Edward had hastily to abandon the conquests which his father had won, with vast expense of blood and a tarnished glory. Some of the particulars are worthy of being mentioned.

Robert Bruce, A. D. 1306.—His first measures of resistance to the lordly sway of Edward were so unhappy, that he had much difficulty to escape with a few followers to the wilds of Athole, where he subsisted in an obscure and precarious manner for some time, and had occasionally to encounter the opposition of his own countrymen. He was afterwards kindly treated by earl Malcolm, and Angus Macdonald, lord of the Isles. His expectations of assistance from Ireland were cruelly disappointed by the capture of two of his brothers, and the rout of a small body of men who adhered to his fortunes. But these and other calamities taught him prudence and moderation, not unmanly despair. He collected a small army with which he obtained a victory over the earl of Pembroke at Lowdon-hill. Edward I. who lay sick at Carlisle, heard of the disasters of his troops, and with his last breath enjoined his son to carry on the war with the rebellious Scots. But that feeble prince was tardy in taking his advice, and unfortunate in putting it into execution. The battle of Bannockburn secured the independence of Scotland, and established Bruce on its throne. Such indeed was the esteem in which he was held, after that event, that the assembly of estates, in their sitting at Ayr, confirmed the kingdom in his family. Nor was his fame confined to his own country. The Irish, disliking the government of the English, made him an offer of their kingdom. This he refused in behalf of his brother Edward, who was slain in an attempt to take possession of the honour. During the short absence of Robert in carrying over supplies to that unfortunate prince, king Edward made an attack on Scotland, but was repulsed. This he repeated on Bruce's return, but with no better success. Bruce afterwards avenged the ravages the English commit-

Civil history.

ted, by an invasion of their country, during which Edward more than once nearly fell into his hands. Peace was finally concluded between the two nations in the reign of Edward III. on condition of the English renouncing all claim to the crown of Scotland, after a contest of seventy years continuance. Robert, whose health had suffered from his severe hardships and fatigues, did not long survive the event. He died at Cardross, whither he had retired from the cares of government, after a reign nominal and real of 24 years. It is worthy of notice among the political measures of this enterprising and able prince, that, on the establishment of his throne, he endeavoured to depress the power of the nobles, which was greater in Scotland than in any other country of Europe. But the attempt had likely to have proved fatal. On his demanding, upon a certain occasion, by what title they held their estates, these haughty chiefs replied by laying their hands on their swords,—a very expressive intimation, at the same time, of their resolution to defend them. Robert Bruce was succeeded by his son,

David II. A. D. 1330,—a minor. The estates appointed Randolph earl of Murray regent, who ratified the peace with England, and applied himself successfully, during the short period in which he held the office, to the preservation of the public weal. In the subsequent regency of the earl of Marr, Edward Baliol son of John, assisted by Edward III. and supported by several factious nobles at home, invaded the kingdom, and with such effect, that he got himself crowned, while David for security was conveyed to France Baliol disgusted the people by his submission to the crafty Edward, and was forced to flee to the protection of that monarch. David was restored after an absence of nine years, but was made prisoner in the battle of Durham during an invasion of England, by which, contrary to sound policy, he endeavoured to aid the king of France, at that time unable to withstand the victorious Edward. He was conveyed to London, and continued captive for eleven years, when he was liberated by ransom, and a truce was concluded for ten years between the two countries. The chief part of the remainder of David's reign was spent in almost fruitless efforts to reconcile his factious subjects, and to introduce among them the virtues and comforts of social life. To him succeeded his nephew,

Robert II. A D. 1370,—high steward of the kingdom, in virtue of a settlement made with consent of the estates, but in opposition to some of the Douglases, a family which at this period had risen to the greatest consequence in the nation. In the commencement of this reign, the truce was broken by the English, and various hostilities were the result, which proved of little moment to either country. Richard II. prepared a large force for the subjugation of Scotland, but his plan was judiciously frustrated by a counter-invasion which rendered it necessary for that monarch to retreat. The two armies returned home after various ravages on their respective enemies, but without having once faced each other in the field. The combats and predatory excursions of the borderers, in this and subsequent times, are fitter subjects for romance than the employment of the historian. They do indeed characterize the times, but had little or no effect on national concerns. To Robert II. succeeded his son John, but whose name by a decree of the estates was changed to

Civil history.

Robert III. A. D. 1390.—It had been more judicious to change the person than the name; for this being an indolent and weak prince, the management of public affairs was committed to his brother Robert, duke of Albany. That unprincipled man formed a plan for usurping the throne, by the murder of his brother's sons. One of these, who had been committed to his charge, was starved to death at the castle of Falkland; the other, afterwards James I. in order to avoid the same noxious influence, was embarked for France, but driven on the coast of England, and carried prisoner to London. The tidings of this event so affected his father that he abstained from food, and died in three days. The government now devolved on the king's brother, whose bravery and prudence were only surpassed by his ambition. In his regency, the Scots gave assistance to France, by sending over an army of seven thousand men, under the earl of Buchan. It was to render their services ineffective, that Henry carried with him the captive James, their nominal king, whom he forced also to remit orders to their leader. But to such commands the Earl gave no heed, smartly remarking, that a sovereign in the hands of his enemies was possessed of no authority. On the death of the regent, his son Murdo was appointed governor of Scotland. He had not the talents of his father, and perceiving that his own children were refractory, at last saw the necessity of calling in a higher power. At his persuasion, therefore, an assembly of the states agreed to demand their prince from the English king. Henry yielded on promise of a ransom; and thus, after a captivity of eighteen years,

James I. A. D. 1423,—ascended the throne of his father. The seizure and detention of this prince were alike ungenerous and unjust. But in the issue, he had no cause to lament them. They preserved him, in all probability, from the evil machinations of his relatives; and from the latter he derived the advantages of an education and a refinement, for which, even if he had possessed the desire, he must have looked in vain throughout his own country, and which in reality shed the highest lustre on his reign. After firmly establishing himself in the throne, he commenced a series of measures, which had for their object the rectification of a great variety of abuses which had crept in through the distractions of the times and the encroachments of the nobility, and the promotion of commerce, learning, justice, and religion throughout his dominions. If Robert I. vindicated the independence of Scotland, it was James I. who redeemed it from ignorance and barbarity, and gave it rank in the list of civilized nations. But this salutary and praise-worthy task could not be performed without offence in some quarter or other. The nobles and clergy in general were most aggrieved by his reforming principles; and some of the former especially, witnessed the comparative diminution of their exhorbitant and impolitic sway with a jealous eye. A conspiracy was at last formed against him, headed by his own uncle, the earl of Athole, which terminated his life by assassination, in the 44th year of his age. His son,

James II. A. D. 1437,—was a minor at his accession, which occasioned the appointment of Sir Alexander Livingston and Sir William Crichton to the management of public affairs, and the custody of the king's person. The altercations of these men, in which their respective friends took part, were most injurious to their country, and the more so as their mutual jealousies and divided counsels enabled the earl of Douglas to establish himself in a sort of independent sovereignty, which for a time claimed almost all the honours, as it seemed to possess all the power of the crown. This was apparently a crisis favourable to the English, who accordingly invaded the country under the earl of Northumberland, but were defeated in Annandale with great loss. After this victory, the king married a daughter of the duke of Guelderland, and proceeded to extremities with Douglas, whom he stabbed with his own hand. The friends of that nobleman were afterwards, on refusing to attend a summons of the states, declared enemies to the commonwealth, and fled to England, where they obtained some aid, with which they invaded the kingdom, but were ultimately repelled. James copied his father in instituting laws, and promoting the civilization of his subjects. He would probably even have surpassed him, if the bursting or accidental discharge of a cannon, at the siege of Roxburgh castle, which he was endeavouring to recover from the English, had not terminated his life too soon for the developement of his plans. This took place in the 30th year of his age. On this distressing and unfortunate occurrence, the queen displayed remarkable energy of mind. She had just arrived in the Scots camp, and learning the disaster, exhorted the soldiers to prosecute the siege, saying she would bring them another king. This was her son, at that time only seven years old, whom the army with triumphant shouts saluted as their sovereign.

James III. A. D. 1460.—During the minority of this prince, eight persons were appointed to administer the affairs of the kingdom; but Lord Boyd, by seizing the person of James, and gaining an ascendency over him, monopolized the authority. This did not long continue, and the devices of that nobleman issued in his own ruin. The king married a daughter of the Danish monarch. He affected, with very inferior talents, to copy the example of his father and grandfather. But he disgusted his nobles by his favour to mean persons, and want of dignity. A conspiracy among them, in which his own brothers took a part, had the aid of Edward IV. but proved ineffective from the death of that monarch. Another actually forced the king's eldest son to declare against him, and led to an engagement which ended his ignoble reign in the 35th year of his age.

James IV. A. D. 1488.—This accomplished and amiable prince adopted a line of conduct which seemed to attain two almost irreconcileable objects, the prosperity of the people, and the affections of the nobility. His marriage too, with Margaret, daughter of Henry VII. promised a lasting tranquillity between the rival nations. It had been well for Scotland if this prospect had not received interruption in the reign of Henry VIII. by the high spirit and vindictive feelings of their respective monarchs, which led to one of the cruellest catastrophes it had ever experienced. James having conducted an army into England, took several places by storm, when his advisers recommended him to retreat, so as to avoid the English under the earl of Surrey, who had been collecting numerous forces, while his own, from various causes, had been considerably reduced. The king, indignant at the proposal, rashly hazarded a general engagement, in which his principal nobility fell, and he himself lost his life. This was the fatal battle of Flouden or Flodden, which, by cutting off the head and chief members of the state, again involved the kingdom in all the natural and adventitious disadvantages of a minority.

James V. A. D. 1513,—was only two years old when he succeeded his father. The queen, his mother, appointed regent, soon lost her authority by marrying the earl of Angus. To her succeeded the king's uncle, John, duke of Albany, a native of France, attached to the interests of that kingdom, and totally unable by his own talents, aided even as he was by foreign power, to controul the aristocracy, which again acquired a dangerous and paramount influence. His chief opponent, in the early part of his administration, was the earl of Hume; and latterly he had to struggle with the intrigues of the queen dowager, sister of Henry VIII. Irritated at last, and disgusted at the difficulties and miseries to which his office exposed him, he retired to his native country. On his retreat, the earl of Angus became master of the king's person, and ruled in his name, in spite of many efforts to deprive him of authority. In him was restored, therefore, the supremacy of the Douglases, which had been before so pernicious to the kingdom. The prince was in reality a prisoner for some time in the hands of that nobleman, who had the audacity to tell him on a certain occasion, that rather than allow him to be taken by the enemies of his family, he would lay hold of his body, and, should it be torn in pieces, would be sure at least of keeping part of it. But James at last escaped, and calling a parliament, deprived the Douglases of their places, and declared them enemies of the state.

About this period, the protestant religion began to dawn in Scotland, but, as usual, experienced opposition from those who were interested to prolong the ancient faith. Patrick Hamilton, a young man of a noble family, who had espoused the reformation when abroad, may be considered its first martyr in his native land. James married first a daughter of the king of France, and, on her early death, secondly, Mary of the house of Guise, at that time of the greatest influence in the same kingdom. He was prevented by his ecclesiastical retainers from holding an interview with Henry VIII. whom they naturally disliked. A war afterwards took place with that monarch, and James found it necessary to court the aid of those noblemen whom it had previously been his endeavour to reduce from their baneful eminence. But they meditated revenge, to the prejudice of national honour, and absolutely refused to cross the frontier, when an opportunity offered of cutting off the English army. Nor did this suffice for the mortification of the king. In a subsequent engagement, his army, amounting to 10,000 men, taking offence at his appointing one Sinclair, a private gentleman, to be their general in room of Lord Maxwell, surrendered to a body of English horse not more than a twentieth part of their number. This disgrace so afflicted the high-spirited James, that he abandoned himself to despair, and died of a broken heart in the flower of his age. On hearing, a little before his death, that his queen had brought him a daughter, his only surviving child, he exclaimed, "The crown came with a woman, and it will go with one; many miseries await this poor kingdom. Henry will make it his own, either by force of arms, or by marriage." These words were partly prophetic. But the rival whom he named did not live long enough to witness the calamities which he predicted. The princess whose birth drew forth this prophecy from her dying parent, was Mary, the inheritor of some of his talents and all his spirit, but who far surpassed him in the experience of misfortune.

Mary, A. D. 1542.—The government of a queen was a novelty which the Scots were far from being agreed to esteem; and that of a queen who was an infant, was still less likely to command their respect. There was yet another reason for uneasy feeling, and the absence of confidence in the present instance, in the omission, on the part of her father, to appoint proper persons as the guardians of her safety, and the directors of her education; even the office of regent he had not filled up; the factions among the nobility, besides, portended disquiet; and to all the other grounds for apprehension, was added a very unsettled state of the public mind on the highly important subject of religious faith. Altogether, then, one can hardly conceive a more unpromising condition than what was now presented in this kingdom.

The first measure of the actual government was, the unprincipled production of a forged testament, by which cardinal Beaton, who had performed the part of prime minister, laid claim to the dignity of regent, which he immediately assumed. This was disagreeable to a large portion of the community, who detested his character, dreaded his bigotted attachment to the ancient religion, and were indignant that the nation should be submitted to the sway of an insolent and illiterate ecclesiastic. Some of the nobles especially testified their dislike, and urged James Hamilton, earl of Arran, and nearest heir to the queen, to accept that high station, in which they were countenanced by the popular voice. This was a well-meaning, but an irresolute and feeble man, very unable of himself to cope with his bustling and crafty rival. He was favourable to the reformation, which now shed a ray of truth and rational freedom across the land,—a circumstance of no small efficacy in obtaining partizans; but, on the other hand, his too evident bias to the political views of the English monarch, who at this time projected an alliance between his son, Edward, and the infant queen, lost him much of the public confidence, and occasioned events very fatal to himself and the kingdom. Beaton, availing himself of this imprudence, and some ungenerous acts of Henry, who appears to have contemplated the entire subjection of Scotland to his dominion, artfully recovered influence with the patriotic nobility, and, by seizing the persons of the young queen and her mother, augmented his power by the authority of the royal name. Arran had not strength of mind to do justice to his own views, but varied with the current of the times. In the month of August he entered into a treaty with the English king, and proclaimed the cardinal an enemy to his country. In the following month he abandoned that alliance, and united himself with the opposite interest. Nor was it long before his religious sentiments became as much altered as his political conduct, when he gave his sanction to the persecution of the protestants. This wavering disposition and fickle behaviour had their usual effects, in rendering him odious to his former friends, and of little or no consequence among his new associates. The cardinal, on the contrary, had attained the height of his ambition, and entertained dread of no one but the earl of Lennox, whose hereditary enmity, and considerable influence, he had previously employed in his own behalf against the regent, but whose disappointed expectations now vented themselves in a change no less remarkable than what that infatuated nobleman had displayed. The contest between these new enemies was decided by the superior artifices of Beaton. Lennox, espousing the cause of Henry, who now sought, by a short but destructive invasion, to resent the indignity he had experienced from the Scots, was at last obliged to seek his safety in the court of that monarch, where he was well received, and where he obtained the hand of Lady Margaret Douglas, Henry's own niece, from whom sprung that race which afterwards filled the throne of both kingdoms.

Henry, blasted in his projects, endeavoured to exclude the Scots from a treaty of peace which he found it necessary to make with France, thinking afterwards to inflict on them more ample punishment. But the generous Francis I. rather than give up his allies, consented to sacrifices which purchased their comprehension. This event, become very requisite to the nation, was made still more agreeable to the majority of the people by their previously getting rid of the cardinal, whose haughty behaviour in general had excited almost universal hatred, and whose severe treatment of the reformers, together with some personal injustice, at last excited the zeal and vindictive feelings of some individuals, which were gratified by his assassination in the castle of St Andrews. This certainly unjustifiable deed delivered the country from an offensive and pernicious man, and in reality was a deathblow to the catholic religion and the French interest in the kingdom. Arran, secretly rejoiced at the fall of one who had eclipsed his authority, for decency's sake affected resentment against the conspirators. These, if not at first instigated, were at all events subsequently supported by the English king, from whom, too, they appear to have expected such military aid as would accomplish a much more important object than indemnity for their offence. But the death of

Henry frustrated their hopes. The ministry of his successor, Edward, resolved to attain the same end by different means; and accordingly the protector, Somerset, entered Scotland with a force intended to compel the acceptance of the treaty which had been so long and anxiously held out as eligible for both countries. Had the prudence of the Scots equalled their number, they must have cut off that able general in his perilous state at Pinkey. But his victory in the fatal battle at that place, however immediately decisive, had little or no effect in forwarding his design, as he himself was under the necessity of returning home in order to guard against the cabals by which he was threatened; and the Scots, on the other hand, so far from yielding to his terms, or submitting to his power, became more resolute in their engagements with France. Indeed, it was from that country alone they could hope for adequate assistance in their present enfeebled and dispirited condition. The queen-dowager, attached by birth, relationship, and affection to the French interest, and who had, on the death of the cardinal, assumed some direction in public affairs, naturally and very sagaciously promoted an alliance which was so flattering to her own inclinations and vanity.

The nobility of Scotland at this period exhibited little of that love of independence, and the unconquerable mind, which had so often borne up their ancestors in equally alarming disasters, and seem to have been panic-struck into a total dereliction of their previous political sentiments. Anxious to wreak their revenge on the English by any means, rather than considerate of the welfare of their country, they hastily fell in with the queen's proposal to offer their sovereign in marriage to the dauphin, and actually to send her to the French court for her education till the period when the alliance could be consummated, as an inducement to favour them with the support which their critical situation required. Henry II. readily acquiesced in a plan which promised ultimate remuneration for any expenditure. Even the immediate effects of the operations which his troops carried on in Scotland served as a diversion, and enabled him to wrest Boulogne from the English.

There were not wanting some patriots who had the sagacity to disapprove, and the courage to censure the policy which reduced the kingdom to the rank of a province, and which accepted for an ally a power that was likely to prove more prejudicial than the ancient enemy whom it was thus intended to provoke and chastise. But events happened differently from what any one might have expected. On getting possession of the young queen, who was carried abroad in the sixth year of her age, the French allowed the war to languish in Scotland; and a revolution in the affairs of the protector, which brought the earl of Warwick into power in England, presented a fair opening for Henry to negociate a general peace. This was accomplished on terms very favourable to France, which alone reaped advantage by the quarrel of the two nations. The Scots, sensible of their error, took umbrage at their allies, whose manners and character they could not relish, and whose insolence became at last intolerable. An aversion to that people now commenced, which had no inconsiderable bearing on subsequent events.

Hitherto Mary of Guise had only covertly interfered in the councils of the nation; but to her aspiring mind it now appeared practicable to attain a legal right to the highest authority. The means which she employed to realize her prospects shewed uncommon penetration, and did justice to her ambition. Various almost insurmountable difficulties were overcome by her artifices, parties most opposed were reconciled to her pretensions, and the regent himself, either intimidated by the growing symptoms of a general defection, or won by arguments more congenial to his feelings, actually resigned his office in her favour.

The first measures of the queen-regent were not of a piece with her usual prudence and moderation. The appointment of foreigners to important stations naturally gave offence; and her visible partiality to French interests, threatened the sacrifice of the welfare and honour of the country whose affairs she was called upon to administrate. It was not long before the dissatisfaction became as public as it was extensive. The nobles, especially, who were in reality what they have been denominated, the leaders of the people, expressed their resentment in a manner not to be misunderstood, and highly galling to her vanity. But she still maintained sufficient influence, and exercised sufficient artifice, to get the marriage-treaty between the young queen and the dauphin accomplished in a way very advantageous to the French, though not without opposition, particularly from the house of Hamilton, whose pretensions to the crown were in material danger of being set aside by the arrangement.

Hitherto the queen-regent, from refinement of policy much rather than regard to their principles, had shewn a conciliatory and indulgent spirit towards the reformers, who for some time past were gradually gaining ground in the kingdom, and who, in return, were by no means remiss in promoting several of her designs. It is singular, on the other hand, that the catholics, whose sentiments were decidedly her own, had not seldom endeavoured to thwart them, and, in the case of the treaty, exhibited a degree of opposition amounting to obstinacy and violence. Neither party, it would appear, understood its genuine interests, or adopted the line of conduct which seemed likely to realize them. So much the more reason, therefore, is there for admiring that providential interference, which, in course of time, and occasionally by adverse agents, brought about an entire revolution in the religion of the country. If, disregarding the operations of a higher power, the inquiry into the causes which produced that event be confined to merely human agents, a degree of sagacity and foresight must be allowed to the promoters of it, which have very rarely indeed been displayed among mankind.

The severities with which they were treated in England, under Mary, induced many of the protestants to take refuge in the sister kingdom, where political motives secured at least protection for their lives, and some degree of liberty for their consciences. Even the archbishop of St Andrews, who geverned the church in Scotland, manifested a moderation and good temper which allowed the new doctrines a fair appeal to the judgment of the people. But the conduct of this prelate being by no means founded on principles of enlightened policy or attachment to the doctrines of the reformation, underwent material change, after the resignation of his natural brother, the late regent, devolved the power of the government into the hands of the queen-mother. Either with a view to thwart her alliance with the protestants, or because he was instigated by the clergy, he began to persecute them with such rage, that they were obliged to apply to her for relief. The queen-regent afforded them protection, but prevailed on them, at the same time, to relinquish their judicious intention of soliciting redress in parliament. This conduct implied an insincerity which ought to have led them to distrust her professions. But her subsequent proceedings left them in no doubt as to the sinister motives which had hitherto prompted her apparent attachment. On the accession of Elizabeth to the throne of England, she lent herself entirely to the designs of her family with respect to that kingdom; and in order to forward them, it became necessary to court the favour of the popish party which had previously sided against her. One effectual mode of doing so, of course, was the very reverse of her former indulgence. But its consequences were quite different from what she anticipated.

On their perfect conviction of the queen's altered intentions to their disadvantage, the protestants ventured, by some of their friends, to expostulate with her concerning a treatment which they had so little merited. Her answer deserves the praise of being at least candid. She gave them to understand that she had really resolved on extirpating the reformed religion out of the kingdom. This extraordinary declaration drew forth a remark which rather bluntly compared her present determination with her former engagements. The queen, irritated at their uncourtly address, lost her usual moderation, and said, "the promises of princes ought not to be too carefully remembered, nor the performance of them exacted, unless it suits their own conveniency." But this harshness was greatly exasperated, on her learning that the protestant religion had been publicly exercised in Perth. She now relinquished all disguise, and proceeding on her avowed determination, summoned all the teachers of that faith to a court of justice at Stirling. The protestants, now united under the name of the Congregation, resolved on protecting, to the uttermost, those persons to whom they looked up as their guides in the most important of all concerns, and agreeably to an ancient practice which permitted persons accused of any crime to be attended to the place of trial by their friends, assembled from all parts of the kingdom to witness the proceedings. Their number was so formidable, unarmed as they were, that the queen thought it safest to dismiss them with a promise that the trial should not go on. A communication to this effect was held so trust-worthy, that the multitude retired to their respective habitations, leaving the preachers with a few leaders at Perth. But no sooner was this perceived, than the queen, utterly violating her word, proceeded to arraign them in ordinary course, and on their non-appearance declared them outlaws. Such a display of falsehood and deceit produced its natural impression. The protestants saw that matters were come to an extremity, and that nothing remained for their safety but the vigorous use of weapons, which some time before they would have regarded as quite irreconcileable with their cause. It was about this period that John Knox returned to his native country, with all the zeal which opposition so naturally excites in an ardent and conscientious mind. His manly but coarse rhetoric had the double effect of exasperating preconceived animosity, and invigorating friendly conviction. The powerful impression made by one of his public discourses at Perth, in which he inveighed against the abominations of the established religion, was most imprudently seconded and enforced on the part of a priest, by preparations for celebrating mass. The effect of the images and relics was electrical on the already inflamed multitude, who speedily manifested the reality and strength of their present belief by the demolition of every object which had formerly claimed their veneration.

Such obnoxious violence, in all probability never contemplated by the reformers, who had hitherto adopted a more rational procedure, filled the queen with rage and hatred. She immediately marched with such troops as she could muster towards Perth, intending to surprise the delinquents. But they, anticipating the result of what had occurred, were prepared for resistance, and soon found themselves able to take the field against her forces. Neither party, however, thought it convenient to hazard a battle; and, accordingly, a treaty was concluded, which offered indemnity for the past, and promised the interference of parliament to compose the existing differences. But the protestants, already deceived by her, and perceiving clearly that these concessions were extorted by her difficulties, bound themselves anew to re-assemble in the event of any violation of faith on her part. Nor was this an unnecessary precaution. The introduction of French troops into Perth, and other measures, demonstrated her perfidious purpose; and the protestants again had recourse to arms in self-defence, and that too with the concurrence of persons who had formerly stood aloof, or were even associated with the queen, but whom her breach of promise and duplicity had altogether disgusted.

Outstripped by their activity, and alarmed at their number and aspect, that ill-judging and faithless woman once more attempted the accomplishment of her designs by negociation. The leaders of tho Congregation, much reason as they had to confide in their strength, and animated now by an additional and powerful principle, the love of civil liberty, which they saw endangered by the employment of foreign troops, and the other measures of the administration, nevertheless had the moderation to consent to a cessation of hostilities, on conditions which not only implied their former demands but also the expulsion of the French from the kingdom. Here, too, her insincerity was manifested, on which the protestants laid

Civil history.

siege to Perth, and, without listening to fresh overtures on her part, soon forced its garrison to surrender. After this they frustrated her intention to seize Stirling, and advanced with rapidity to Edinburgh, which she abandoned on their approach, and where the inhabitants in general hailed them as their friends. They now resolved on fixing their residence in the capital, and establishing the Protestant religion on the ruins of Popery. Knox, and some of his brethren, were accordingly appointed to the vacant pulpits, in which they laboured with equal ardour and success.

In the meanwhile, the Queen lay at Dunbar, waiting when their indiscretion, or a relaxation in their vigilance and exertions, should give her an opportunity of attacking them with effect. This soon presented itself; and she advanced unexpectedly on Edinburgh, which, in spite of their resistance, they found it necessary to preserve from her violence, by concluding a treaty, by no means so favourable to their wishes as their former success might have induced them to expect. The Queen, on the other hand, was the rather induced to defer hostilities, because she daily looked for the arrival of more troops from the continent. But the affairs of the Congregation, though critical, were far from being desperate at this period. A benefit even was gained by the Queen's recent advantages, inasmuch as they gave occasion to some of the chief adherents to the established religion, who had hitherto followed her, to perceive her design of reducing the kingdom to the condition of a province of France, which their patriotism could not tolerate. Thus the late regent, now the duke of Chatelherault, again changing his views, and the earl of Huntly, after the conclusion of the last treaty, promised the leaders of the Congregation, that in the event of their witnessing any farther deception, or a violation of faith on the part of the Queen, they would unite with their countrymen in efforts to preserve their national independence. Circumstances were not long wanting to require the fulfilment of this engagement.

On the accession of Francis II. to the crown of France, the family of the Guises, to which the Queen regent belonged, assumed the chief management of the affairs of that kingdom, and determined, with as much energy as might be required, to aid their relative in suppressing the Protestant religion, as one important step to their ambitious designs on England. For this purpose, they resolved to commence at home, by selecting a victim whose consequence might give the greater effect to the punishment which they meditated. This was the earl of Arran, eldest son of the duke of Chatelherault, who had long resided in France, where he commanded the Scottish guards, and where he had of late somewhat indiscreetly avowed his approbation of the new doctrines. But this nobleman taking alarm at certain expressions of the cardinal of Lorraine, made his escape into Scotland, where he communicated his sentiments and his indignation to his father, who, together with himself, soon afterwards joined the Congregation as their nominal head, James Stuart, prior of St Andrew's, a natural son of James V. being in reality their chief mover and adviser. This singularly able man merited that distinction and confidence, not more by the superiority of his talents, his military skill, and personal bravery, than by his resolute attachment to the principles of the reformation.

The arrival of some French troops relieved the Queen in part from her uneasiness at the loss of the duke. They were immediately employed in fortifying Leith, which gave great offence, and drew forth a spirited remonstrance from the lords of the Congregation. To this the Queen paid little regard. She proceeded even to an action still more odious, in direct contravention of the treaty agreed on,—the seizure of the church of St Giles in Edinburgh, which was again employed in the service of the Romish faith. It now appeared absurd to hope for redress, or any amicable proceeding from the Queen, and accordingly the protestants felt themselves compelled to take arms in their own defence. The Queen retired into Leith, already sufficiently fortified to withstand an army unprovided with the requisite artillery for prosecuting a siege; here she endeavoured, by various artifices, to weaken or divide the force which threatened her; and her labour was not altogether fruitless. But her subsequent behaviour, when another remonstrance was presented to her, counteracted all the effects of her stratagems and insinuations. Her haughty declaration of independence, and an order to disband, on pain of treason, convinced the leaders of the Congregation that nothing but the most decisive conduct on their part could ensure their safety. They accordingly assembled all the principal persons of their party, and formed a convention, exceeding in number the ordinary parliament, in which they proposed the difficulties and dangers of their situation, and solicited the requisite direction and assistance. Here, after a short but solemn deliberation, in which Knox took an active part, as representative of his order, it was unanimously determined to deprive the Queen of the office of regent, a decree which was conveyed to her in a letter from the lords of the Congregation, couched in the most energetic and perspicuous language.

An unsuccessful attack on Leith, made after this event, occasioned great dissatisfaction and murmuring among the adherents of the Congregation. To allay these discontents and inspire new hope, it was resolved to apply to the English queen for assistance. Nothing could give Elizabeth more pleasure than such an opportunity of opposing the designs of her foreign enemies, or extending her influence in Scotland. She promised her support, and shortly afterwards sent a small sum of money, which unfortunately was intercepted on the way. This was a grievous disappointment to the reformers, and, to add to it, a skirmish with the French troops in the neighbourhood of Leith, was terminated very much to their disadvantage. They were now so much dispirited that they retreated hastily to Stirling, and their numbers began gradually to diminish. Another address to Elizabeth, through Maitland of Lethington, who had recently deserted the Queen-regent, and joined the Congregation, seemed the only remedy for their alarming difficulties. This was eminently successful, in leading to a treaty, which proved of the most essential service to their cause. In the meanwhile, the queen regent sent out some of her forces to ravage the county of Fife, as peculiarly obnoxious, from its general attachment to her opponents. These were cordially employed in the work of destruction, and were preparing to advance on St Andrews, when the unexpected appearance of an English fleet in the Forth, at first taken for a French reinforcement, obliged them hastily, and in a very wretched condition, to retreat to Leith by the circuitous route of Stirling.

A new era opened for the Congregation on the arrival of Elizabeth's promised aid. The Queen-regent sought refuge in the castle of Edinburgh, in a state of health which threatened her dissolution at no great distance of time; and the English army, under Lord Gray, laid siege to Leith, in which she had placed her chief support. Her death took place during the protracted operations against that fort; and at last there remained no chance of escape for the French troops but the acquisition of reinforcements from their own country, or the conclusion of a peace. The former was rendered impracticable by recent events at home; and, accordingly, negociations for the latter were entered into with all imaginable celerity. These terminated in the treaty of Edinburgh, formerly mentioned, which at once relieved Scotland from its enemies and its allies, and decided a long, arduous, and complicated struggle in favour of the reformation, which was subsequently proposed, discussed, and ratified by parliament. The proceedings of this assembly were communicated to queen Mary, still in France, and her husband Francis, by whom they were much disliked, and also to queen Elizabeth, whose political views ensured them a more favourable reception, though she rejected, on her usual grounds, a proposal for perpetuating the friendship of the two countries by her marriage with the earl of Arran.

The death of Francis gave no small joy to the Scots, as an event which promised the entire establishment of the protestant faith, and the acquisition of political liberty, without the interference of a foreign associate, clothed with the authority and influence of husband to their queen. The principles and outlines of the presbyterian church were now determined on the model of that which Knox had so warmly approved in Geneva, but with such modifications, and in as cautious a manner, as circumstances required. A convention of the estates, in which various ecclesiastical regulations were accomplished, finally resolved on inviting their queen, now a widow, and retired from the French court, to return to her native country, and assume the reins of government. She was received with demonstrations of joy, but with a paucity of pomp which little gratified her taste; and though permission for her exercising it was at last obtained, she soon perceived that only scanty indulgence would be allowed to her notions of religion, by a people who had contended so long, and so obstinately, against the superstitions and profane ceremonies of her faith. Yet with good guidance and moderation on her part, coupled with the affection and esteem of the nobles, it might have been reasonably expected that her reign would prove equally honourable and beneficial. Nor were some of her first measures calculated to destroy such a hope. She employed protestants exclusively in her administration, studied, at least for a time, to secure the good understanding of the English queen, dispensed justice in an impartial manner, and contributed to the refinement, if not the comfort of her subjects. If it be impossible altogether to justify her subsequent behaviour, or with propriety commend her character, it is no less so to withhold some lenient consideration for the number and magnitude of the difficulties with which she was beset. Her youth and inexperience, the prejudices of her education and early habits, the allowable foibles, or at least pardonable infirmities of her sex and station, judged of in relation to the new and extraordinary exigencies of the times, and the natural or superinduced peculiarities of her subjects, present every adequate reason for moderating censure, though they may not exempt her from an unfavourable verdict.

The dissensions and jealousies of the nobility were among the first difficulties which she had to encounter. Her favour for the prior of St Andrews, whom she created earl of Murray, excited umbrage in the duke of Chatelherault and the earl of Huntly, which had very unhappy effects. Then a disturbance arose at Edinburgh about her religion, which threatened disagreeable consequences. But a still more serious difficulty presented, in the choice of a proper person for her consort. Several suitors proposed themselves, or were proposed by others for her acceptance, and of course with various degrees and kinds of advantage. Her deliberations on the subject merit the praise of attention to the interests of her subjects, although it be very questionable if her decision were as much calculated to promote them, as it seemed to gratify her fondness for personal accomplishments. A powerful party highly disapproved her preference of the lord Darnley; and the earl of Murray, in particular, manifested his dislike and objections in a manner very offensive to her feelings and pride. This nobleman was at last obliged to take refuge in England, where the crafty Elizabeth, who had in reality concurred in his opposition for her own ends, treated him and his associates with public indignity, but at the same time privately supplied them with money, and interceded in their behalf.

Mary, so far successful against that able man, reconciled the people to her choice, created her youthful husband king of Scotland, and proceeded to levy fines on such of the towns as had shewn adherence to her banished opponent. She afterwards relented in her intentions respecting him and his friends, notwithstanding the obdurate disposition of her husband, and absolutely agreed to recal them and treat them with gentleness, when the arrival of a French embassy, charged with solicitations to enter into an alliance for the extirpation of protestantism, changed her resolution, and in reality the whole plan of her administration. Her rash engagement in this abominable scheme, was the origin of most of the perplexities and miseries which she afterwards experienced. The revolution in her sentiments and political views was immediately manifested, but soon received interruption by an event, apparently of a private, and, excepting the guilt and barbarity of the

Civil history.

actors, a trivial nature, but which may be justly considered as instrumental in preserving both Murray and the protestant cause from destruction.

Darnley, a man of weak judgment, but of strong passions and vicious habits, soon perceived the diminution of his royal consort's love and esteem. This altered regard his jealous imagination ascribed to an undue fondness for one Rizzio, an Italian, whose skill in music and other qualifications had somewhat rapidly, though innocently enough, procured her approbation and confidence. The earl of Morton, lord Ruthven, and others, some of whom were on different grounds inimical to this foreigner and favourite, concurred in Darnley's suspicions, and entered with him into a plan for the murder of their victim. This they effected in a savage manner, in the palace of the Queen at Edinburgh, almost before her eyes, and without the smallest regard to her entreaties, or her delicate condition of pregancy. After this horrid deed, the conspirators, who had farther objects in view than the gratification of personal hatred, took possession of the palace, and set a guard upon the Queen. Darnley, moreover, prohibited the intended meeting of parliament on the day appointed, and took measures for preventing disturbances in the city. Murray and his associates, apprized of the resolutions against Rizzio, arrived there in the following evening, and were afterwards graciously received by the Queen, who hoped, by their means, to induce her husband to act against the very persons by whom, partly at his instance, the blood of her domestic had been shed. In this she perfectly succeeded,—that foolish and headstrong youth abandoning his accomplices, who fled into England, and being audacious and weak enough to issue a proclamation, in which he denied all participation in their crime, though in a manner calculated more powerfully to convince her of his guilt.

But no acquiescence in any of her measures could ever restore to Darnley the lost affection of his consort, or remove the disgust and aversion which his meanness and odious practices excited. It was impossible for him, at last, with all the privileges and the rank of royalty, to retain authority, or command even the semblance of respect among the usual retainers of a court. The birth of a son, afterwards James VI. an event which might have been thought likely to reconcile and cement the union of the parents, had no such salutary effects. Mary, unfortunately alike for her happiness and her reputation, besides having irrecoverably steeled herself against him, had gradually opened an avenue for the approaches of a more insinuating personage. The earl of Bothwell, a man of talent and address, but dissolute and ambitious, had, by various services, merited the gratitude of his queen, who did not fail to testify it by sundry rewards, and the ascendancy in her councils. In a heart so susceptible of tender and kindly emotions, and so grievously disappointed in the object of its love, it is not improbable that feelings of a warmer nature speedily arose, and that the confidential adviser of Mary, became, in no long time, the master of her affections, though there be no evidence of criminality of conduct between them, on which any thing like conviction can be founded.

The designs of Bothwell became elevated with his success, and ultimately carried him beyond the most sacred bonds of allegiance and humanity. Darnley, perceiving his complete and irremediable degradation, formed a notion of leaving the kingdom, which was with much difficulty prevented from being put into execution. He was afterwards taken dangerously ill at Glasgow, but received no attention from his consort, perhaps in retaliation for the neglect she had before experienced during her own indisposition at Jedburgh, or perhaps owing to the nature of his disease, which in those days was imagined so contagious, that persons labouring under it were removed without the walls of cities. But her conduct was visibly and strangely altered on his becoming convalescent. She then visited him, and manifested such concern for his welfare, as can scarcely be reconciled either with her former indifference and contempt, or the notion that she was in no respect practising on his credulity, in order to forward the fate which awaited him. Be this as it may, it is certain that she succeeded in inducing him to return to Edinburgh, in the immediate neighbourhood of which a retired place was prepared for his reception. Here she continued to wait on him with becoming care for some days, though, at times, partaking of the amusements of the palace. It was on one of these occasions, that, early in the morning, the house in which Darnley lay was blown up with gunpowder. The alarm of the explosion soon brought the inhabitants to the spot, when the bodies of that unfortunate man and the servant who usually slept in his room were found lying in an adjacent garden, dead and naked, but without any marks of violence, or the least appearance of having been touched by the fire.

A deed so atrocious and so decisive, naturally excited popular suspicion, which glanced, with no qualified force, on Bothwell, if not also on the Queen. Their subsequent behaviour afforded confirmation to the charge, and assuredly manifested every inclination to profit by the catastrophe. A trial, at the instance of Darnley's father, declared the former not guilty, the accuser finding it unsafe to make his appearance, and the judges being previously instructed how to proceed. Bothwell afterwards constrained a party of the nobles to forward his views on the Queen, whom he seized on the road to Stirling, probably by concerted arrangement, and carried her to Dunbar castle, where she yielded to his ardent solicitations, and accepted him for her husband. They were afterwards publicly married, Bothwell having obtained a divorce from his former wife, but not without very unequivocal manifestations of popular umbrage, and expressions, or appearances, of disapprobation on the part of all whose judgements were deserving of attention.

There now wanted only the title of king to make Bothwell's conquest complete. He possessed, in reality, regal power, and maintained entire sway over the will of Mary. But his triumph was of short duration. His efforts to acquire possession of the infant prince were abortive, through the manly and loyal behaviour of the earl of Marr, to whom he had been committed. His haughty carriage, and the reiterated reproaches of foreigners, who were univer-

Civil history.

sally struck with horror at the transactions which had recently taken place in Scotland, at last roused the nobility to some spirited resolutions. A combination against both was the result, by which, after some shew of resistance, and only a month after their marriage, Mary was obliged to surrender herself to the confederates, and her paramour, with a few adherents, rode off the field, where he had vainly endeavoured, with her co-operation, to urge their army to battle in their behalf. The Queen was now conveyed to Edinburgh, more like a culprit than a sovereign, and entered it in a state of fatigue and wretchedness which failed to excite the slightest emotions of compassion or sensibility among the people, the surest of all indications of the abhorrence and dislike in which her conduct was generally viewed. Nor did the confederates stop here. They proceeded to still more vigorous measures, as requisite for their own safety, and the welfare of the kingdom. Having first of all confined the Queen a prisoner in Lochleven castle, they, in the next place, notwithstanding some opposition on the part of several of the nobility, compelled her to resign the crown in favour of her infant son, and appointed the earl of Murray regent. A meeting of parliament confirmed these deeds, and declared the imprisonment of Mary to be legal. She afterwards made her escape, and, collecting some of her friends, ventured unsuccessfully to engage the army of the regent at Langside near Glasgow. On her complete discomfiture in this last struggle, she fled into England, where, after a long captivity, she terminated her days at the block, as already related. Thus was accomplished a revolution almost unparallelled in history, for the expedition, limited means, and nearly bloodless efforts with which it was prosecuted. The wretched Bothwell, one of the chief actors in this extraordinary drama, fled from place to place, a vagabond, destitute, deserted, despised; become a pirate for subsistence, he was captured by the Norwegians, saved from an infamous death merely by his more infamous notoriety, but consigned to perpetual and rigorous imprisonment, where he languished for ten years, a prey to remorse, melancholy, derangement, and despair, and where he ended his ignoble life, without an eye to pity his miseries, a hand to relieve his necessities, or a heart to respect his memory.

James VI. A. D. 1567.—The vigorous regency of Murray was of short continuance, but it secured the authority of the young king, and effectually subdued the party which remained attached to Mary, without any remarkable display of severity. His proceedings against that princess herself, during the singular conference which undertook to investigate her conduct, are less easily explicable to his advantage. On his death by assassination, the Queen's friends revived their hopes. They obtained possession of Edinburgh, and projected a war with England, in behalf of their captive sovereign. But the king's party, assisted by Elizabeth, ultimately prevailed, and, at her suggestion, appointed the earl of Lennox to the vacant regency. The kingdom at this period was distracted by factions of various kinds, in which it was no nowise unusual for members of the same family to take opposite sides, and contend with rancorous animosity. Lennox was one of the sufferers in an assault on the king's party, during its sitting in parliament at Stirling, and was succeeded by the earl of Marr, whose patriotic spirit and virtuous behaviour deserve the highest encomium. Disappointment at the failure of his project for a general peace, greatly through the ambition and avarice of the earl of Morton, terminated his life, with the esteem, if not the affection, of all parties. To him succeeded that able nobleman, who was supported by the queen of England, in opposition to the fears and jealousies of the people. The commencement of his regency was marked by a singular innovation in church government, which had more for its object, at least in the first instance, the advantages of the nobility, not forgetting Morton himself, than the welfare of the community. This was the appointment of ecclesiastical officers, according to the principles of the episcopal establishment, but privately subject to a kind of copartnery, by which the patrons reaped the chief temporal advantages of the respective sees. John Knox lived long enough to witness this gross vitiation of a system for which he had so long and so energetically contended.

Morton now laboured, not without success, to compose some of the differences which agitated the kingdom. But his measures partook too much of the covetousness and severity of his character to give general satisfaction. The disorders and misery of the country became at last so great, that some of the nobles, who were disgusted at his administration, prevailed on James, now twelve years of age, to deprive him of his office, and undertake the concerns of government. Morton, apprised of their intentions with respect to him, resigned the regency, and retired to one of his seats, but watched for an opportunity of recovering his authority; and this soon offered; for the possession of the king's person gave him a decisive advantage over his opponents, which he did not fail to improve. But there soon arose new obstacles to his enjoyment of power, in the two individuals whom James now singled out as his favourites and companions. These were, Esme Stewart, a member of the Lennox family, and James Stewart, the second son of Lord Ochiltree. Their efforts against him completely succeeded, notwithstanding his own influence and the mediation of queen Elizabeth. He was accused of the murder of lord Darnley; tried in a hasty, irregular manner, by a jury of his enemies, and on evidence partly extorted from the witnesses; the result, of course, justified the means used to accomplish his ruin; and he was condemned and executed.

The imprudent proceedings and undue influence of the favourites, now excited universal uneasiness; a party of the nobles united to free James out of their hands; and this object they accomplished somewhat rudely, by seizing him during his entertainment at Ruthven-castle, whence this singular enterprise has been called *The Raid of Ruthven.* But this deed, violent and hazardous as it was, the king was obliged to approve; and it afterwards received the most favourable interpretation from an assembly of the church and the convention of estates. James, however, who had only dissembled, afterwards escaped from the conspirators, whom he required to deliver themselves prisoners, on pain of being guilty of high treason, and whom, in defiance of his promises and engagements, he treated with unbecoming and very impolitic severity. This was owing to the ascendancy which one of his favourites again acquired over him, whose profligate manners and violent counsels justly roused indignation and abhorrence throughout the country. Odious as the conduct of the king, thus biassed, had proved, it was rendered still more irritating by his interference in church concerns, and his behaviour to the clergy, most of whom disgusted, offended, and injured in their rights, forsook their charges, and fled into England.

Elizabeth, in order to guard more effectually against the adherents of Mary, thought proper to court a good understanding with James's favourite, now the earl of Arran. This enabled him to proceed with more activity against those nobles and their friends who had formerly been banished. They were accordingly attainted and their estates seized by that worthless creature and his associates. But in course of time, it became no less for the interest of the English queen, or at least the success of her projects, to undermine the power of this individual, and to assist the objects of his vengeance. For this purpose she gained over the needy James to her views, and concluded an alliance between the two kingdoms in defence of the protestant religion. The banished lords now returned to their country, were reconciled to their sovereign, and witnessed the downfal of their opponent, the favourite, who was stripped of his honours and dishonest gains, and declared an enemy to the state. Still the clergy were little considered, and obtained scarcely any redress of their grievances; a neglect partly owing to James's obstinacy, and partly to a breach of promise in those who now came into power. Soon afterwards occurred that conspiracy against Elizabeth, the detection of which served as a fit opportunity for accomplishing the removal of her royal captive. James, who had, not long before, written a cruel letter to his mother, in which he refused to own her as queen, or in any measure connect his interest with hers, interceded in her behalf, and even threatened a rupture if his solicitations were not regarded,—a spirit in which, to their honour be it recorded, his nobility shewed a hearty concurrence. But the artifices of Elizabeth prevailed, both in executing her ungenerous purpose, and in preventing any consequent explosion on the part of Scotland. Indeed, it is to the credit of that queen's politics, though it imply little heroism in her contemporaries, that no prince had resolution enough to avenge a fate, which, with the exception of her own panic-struck and deluded subjects, was universally deplored.

James now endeavoured, with greater humanity and politeness than success, to reconcile his nobility to each other. A more efficient measure was the care of parliament to ratify all the laws in favour of the protestant religion, which had passed since the reformation. This was followed by the annexation of the church lands to the crown, which afforded only a small aid to the necessities and foolish liberality of the king. A change was also made, at the same period, in the civil constitution, which deserves notice. This was the revival of an act of James I. dispensing with the personal attendance of the *lesser barons* in parliament, and appointing the election of two commissioners from each county, as their representatives. This was opposed by many of the nobility, whose authority was thereby diminished, but was at last carried into effect, and henceforward the commons of Scotland sent representatives to parliament. The good sense thus displayed in James's administration continued in the friendly part he took with Elizabeth, against the designs of the Spanish king, now intent on the invasion of England. He resisted the solicitations of Philip in a manner which left no room to doubt the sincerity of his attachment, or his conviction that the subjugation of that kingdom by a foreign power could never profit, but might be fatal to the sister country. The resentful intrigues of Philip, after the destruction of his far-famed Armada, gave rise to a conspiracy among the popish nobles against the Scottish king; but it was fortunately discovered in good time, and afforded another opportunity to James for shewing the moderation and lenity of his character. A short imprisonment was all the punishment awarded to the leaders of this criminal association.

Relieved from his apprehensions either of foreign or domestic foes, James resolved on an event which might perpetuate the crown in the direct line of the royal blood. In spite of the opposition of Elizabeth, who seems always to have disliked any measures which promised greater security to the house of Stuart, he fixed on Anne, the eldest daughter of the king of Denmark, as his consort, and, on the occurrence of a storm which drove back the fleet intended to bring her to Scotland, actually fitted out some ships and went in quest of her. He arrived safely in Denmark; the marriage was solemnized; and he afterwards passed several months at Copenhagen. The kingdom enjoyed perfect tranquillity during his absence, all ranks appearing to vie in demonstrations of loyalty and attachment. One of his first acts on returning home, testified his gratitude for the fidelity and good services of the clergy, during the time of his being abroad. After commending the discipline and doctrine of the church, and promising inviolably to adhere to both, he permitted an assembly to take such steps as would abolish every vestige of episcopacy, and lay the foundation for the presbyterian model, which soon obtained all the formality and sanctions of a legal establishment. But these concessions, it is certain, were far from being agreeable to the feelings or opinions of James, who disliked a system which savoured so much of a republican nature, and many of the members of which were more remarkable for staunch adherence to their own notions of propriety and moral virtue, than those graces and that courtly deportment which are in general so requisite to secure the approbation of royalty. The remainder of his reign in Scotland was chequered with contentions in which they took an active part not much to the honour of their moderation, and naturally enough calculated to excite disgust in a mind even less pertinacious and conceited than that of James. It was marked also with various plots and

Civil history.

conspiracies, partly owing to his excessive lenity towards offenders, and partly to the turbulence and disaffection of some of the nobles. That one known under the name of *Gowry*, was of a very peculiar nature, and has often exercised the ingenuity of historians. In the latter years of queen Elizabeth, he was careful to improve his interests in the English court; and on the death of that princess, who declared him her successor, after an affectionate farewell to his ancient people, he prepared with gladness to assume the new and splendid honour which awaited him. His accession to the crown of England united the interests of the two kingdoms of England and Scotland, and henceforward their history is properly that of one monarchy.

Chap. III. History of Great Britain.

James I. 1603.—On the death of Elizabeth, James VI. of Scotland succeeded to the throne, and was the first of that name who reigned in England. Notwithstanding the animosities which had long subsisted between the two kingdoms, all ranks among the English united in hailing his accession with demonstrations of joy. But his imprudent partialities in bestowing his favours, and his suspected predilection for his Scottish courtiers, rendered his popularity of short duration. Scarcely had he arrived in London when a conspiracy was formed against him, with a view to transfer the crown to Arabella Stuart, a near relation of his own, and equally with himself descended from Henry VII. Of the conspirators, who, excepting Parkham, were all convicted of high treason, Sir Walter Raleigh was condemned, on incompetent evidence, to many years confinement in the Tower before he suffered.

The puritans, who had been greatly oppressed during the reign of Elizabeth, welcomed James to the throne as an event auspicious to religious liberty; thinking that, as he was the king of a presbyterian nation, he could not fail to promote, or at least to tolerate the ecclesiastic system which they had embraced. In this, however, they were soon undeceived; for, induced by their growing disputes with the church, James, in 1604, called a conference between the parties at Hampton-court, when he evinced, by the share which he took in the controversy, his decided aversion to what he considered the republican principles of the puritans. On this occasion he defended his favourite maxim, "No bishop, no king;" and so pleased were the established clergymen present, that bishop Whitgift, one of their number, said, he verily believed the king was inspired.

Nor were the Roman catholics less disappointed in not receiving that religious indulgence which they anticipated under James, the son of their avowed friend, Mary, the Scottish queen. Prompted by motives of revenge, they devised a scheme, the most barbarous and inhuman which the annals of history have recorded; they determined to extirpate heresy from the land, by consigning to destruction, at the opening of the approaching parliament, in November 1605, the Lords, the Commons, and all of the royal family who were expected to attend. For this purpose, having hired the vaults under the houses of parliament, they secretly conveyed into them thirty-six barrels of gunpowder, which they carefully concealed among coals and faggots; and, to prevent all suspicion, boldly threw open the doors, that any person who chose might enter and examine the place. In the meantime, Sir Henry Percy, one of those embarked in the diabolical enterprize, addressed an anonymous letter to his intimate friend Lord Monteagle, beseeching him to keep away from the commencement of that session, "for God and man had concurred to punish the wickedness of the times." This letter was submitted by Monteagle to Lord Salisbury, secretary of state, who laid it before the king in council; and his majesty was the first to unravel its meaning, and to suspect the evil which it threatened. An order was given to search the vaults, and one Guy Fawkes, an officer in the Spanish service, was found about midnight, just when he had finished his preparations, with a match in his pocket to set fire to the train. This hardened wretch was immediately seized, and committed to the Tower; but from a sullen obstinacy, arising perhaps from the despair of pardon, refused to discover his accomplices, until his spirits were subdued by the exhibition of the rack, on which he was about to be tortured. Soon after, the conspirators, about eighty in number, were taken and put to death in different parts of the country.

England and Scotland, although now governed by one sovereign, had each a separate and independent parliament. James saw clearly the advantages which would result from their being united under one legislature; and in 1606 he turned his attention towards the promotion of this desireable object. But his proposal, notwithstanding it was supported by Sir Francis Bacon with all the energies of his powerful mind, met with determined opposition in the invincible prejudices of the Commons, so that the business was given up as impracticable at the time. Hitherto their influence in checking the authority of the crown had been so inconsiderable, that they deemed it unnecessary to record their transactions; and it was not until 1607 that the practice of keeping regular parliamentary journals commenced, when a motion was made to that effect by Sir Edward Sandys.

The speculative system of arbitrary power which James had adopted, was fully displayed in his first conference with his English parliament. While his ministers and courtiers seconded his views of absolute government, the Commons boldly resisted every attempt to annihilate their civil liberties. By his inconsiderate profusion he soon experienced pecuniary embarrassments; and in 1608 the lord treasurer Dorset stated his necessities to the Commons, who boldly refused to grant the wished-for supplies. In 1610, when, by commission, the earls of Suffolk and Salisbury opened a new session of parliament, money was again demanded, on this ground, among others, that L.350,000 had been absorbed in paying off the debts of Elizabeth. But this only produced a counter-demand on the part of the Commons, for a redress of the national grievances. The king was so displeased, that having admonished them "not to meddle with the main points of government that was his craft, nor to pretend to instruct a king who had been thirty years at the trade in Scotland, besides an apprenticeship of seven years in England," dissolved the parliament.

The year 1612 witnessed an improvement in the civilization of Ireland. Previously to this period enormities of the most criminal nature, such as murders, rapes, and robberies, were, by the *brehon* law, atoned for by fines, called *eric*, while, for oppression, extortion, and other less offences, no redress whatever could be obtained. James bent all his efforts to the abolition of this and similar barbarous customs, and so completely did he succeed, that, by substituting the English law in their place, and by keeping up a small, but well disciplined army, he exalted the country to a degree of moral amelioration, and composed it to a state of tranquillity to which it had hitherto been a stranger.

On the 6th November in the same year, an event took place which cast a melancholy gloom over the whole nation. This was the death of Henry, prince of Wales, in the 18th year of his age; a prince universally beloved, fond of martial exercises, possessed of splendid accomplishments, and free from those irregularities which too often, especially in the fervour and thoughtlessness of youth, follow in the train of rank and fortune. But the grief thus occasioned was, on the 14th of February following, in some measure removed by the marriage of the princess Elizabeth to Frederick, elector palatine; a marriage which by no means proved fortunate either to the king or his son-in-law.

James having convoked his second parliament in 1615, for the purpose of recruiting his treasury, which had been considerably exhausted by the sums which had been lavished on his worthless minion, Robert Carre, met with a spirited and steady resistance from the Commons. Instead of listening to his request, they again demanded a redress of grievances; and he became so provoked, that he dismissed them without obtaining his object. The king, however, was not to be driven from his notions of absolute power. One day he put the question to two of his courtiers, whether, laying aside the formality of parliaments, he might not at any time take the money of his subjects to supply his necessities? "God forbid," replied Neale, bishop of Durham, "but that you should; for you are the breath of our nostrils." This question being next proposed to Andrews, bishop of Winchester, he answered, "Your majesty might lawfully take my brother Neale's money, because he has offered it."

In 1617 James visited his native country with the view of establishing in that kingdom the English hierarchy, of which he was a strenuous supporter. Before this the episcopal form of worship was there but partially acknowledged, and the feeble authority of the Scottish bishops had always met with a powerful counteraction in the zeal and exertions of the national presbytery. The king having called an assembly of the subservient ecclesiastics, obtained a declaration that the following articles, commonly termed "the five articles of Perth," the place where that assembly was held, should in future form a part of the Scottish ritual; namely, 1. The use of the cross in baptism; 2. Confirmation; 3. The observance of holidays; 4. The receiving of the Lord's Supper in a kneeling posture; and, 5. The administration of private baptism to infants. But these articles, which were ratified by a small majority of the Scottish parliament, were so offensive to the great body of the clergy, and of the people, that they were soon after rejected with disdain.

After thirteen year's imprisonment in the Tower, Sir Walter Raleigh obtained his release, though not his pardon, by giving out that he knew of a gold mine in Guiana, which promised immense treasures to the British nation. He accordingly embarked for the New World, with a force sufficient to overpower the Spaniards, who had formed a small settlement on the river Oronoko, not far from the spot where the riches were said to be found. On his arrival he sent a detachment on shore, who met with a bloody reception from the settlers; in the action his son was slain, and the town of St Thomas reduced to ashes. The other adventurers, thinking themselves duped by their leader, despaired of success, and, abandoning the enterprize, returned with him to England. The privy-council accused him of having abused the king's confidence; Spain demanded indemnification for the loss he had caused her to sustain; and James signing the warrant for his execution on his former sentence, this great man was, in 1618, beheaded in Palace-yard, Westminster.

The states of Bohemia, inspired with the love of religious liberty, in 1619 took up arms against the emperor of Germany, in defence of the protestant cause. Calculating on the relationship of the elector palatine to his Britannic majesty, and to prince Maurice, stadtholder of the United Provinces, the Bohemians made a tender of their crown to Frederick, who having incautiously accepted the offer, plunged himself into a disastrous war with a powerful enemy. He was defeated in the decisive battle of Prague, stripped of his new dignity, despoiled of the palatinate, and obliged to seek in Holland an asylum for himself and his family.

From an extreme reluctance to break with Spain, in consequence of a proposed match between the infanta and Charles, prince of Wales, James refused his son-in-law that assistance which his necessities required. The murmurs of the British nation, excited by their compassion for the suffering protestants, were loud and reiterated against the king for such callous neglect. Yet, in consideration of some money he remitted to Frederick, the Commons, in 1621, voted him considerable supplies. In return he redressed several grievances of which they complained; and the high chancellor, Francis Bacon, a man universally admired for the splendour of his talents, and the sublimity of his genius, was, for his bribery and corruption, fined L.40,000, doomed to imprisonment in the Tower, and declared incapable of holding any public office in future. But he was soon after relieved of the fine, restored to liberty, and permitted to retire on a pension of L.1800 a-year. The Commons, however, in the plenitude of their zeal, proceeded to such minute examination into abuses, that the king becoming jealous of his prerogative, dismissed the parliament with expressions of the greatest displeasure.

Next session, in the same year, the Commons, indignant at the indifference of James to the situation of his son-in-law, and to the protestant interest in Germany, remonstrated with him against the intended marriage of prince Charles with the infanta of Spain. The king replied, that they had not understandings to scan his measures, and that it did not belong to them to meddle with the deep matters of state, excepting when he chose to ask their opinion. This reply produced a protestation, in which they maintained that "the liberties, franchises, privileges, and jurisdiction of parliament are the ancient and undoubted birth-right and inheritance of the subjects of England;" a protestation which he in a rage tore with his own hands from the journals of the house, and ordered his reasons to be inserted in the council-book. Having imprisoned the leading members in opposition, he dissolved the parliament. From the date of these transactions, politics became a favourite subject of discussion throughout the nation; those who took the side of liberty were, for the first time, distinguished by the name of *Whigs*, and those who supported the regal authority were denominated *Tories*.

The elector palatine began, in 1622, to make some efforts for the recovery of his dominions. But James, who, for his pusillanimity, was contemptuously depicted sometimes as wearing a scabbard without a sword, and, at other times, as having a sword, which many hands pulling at it were unable to unsheath, prevailed on his son-in-law to desist from the unavailing enterprise, and to trust for the accomplishment of his object to the efficacy of his negociations. The pacific king rested the success of these negociations on the mediation of Spain; and, in order to induce the Spanish monarch the more readily to enter into his measures, by hastening the projected marriage, he made some concessions in favour of the catholics in England. Matters were now in a fair train of settlement, when the hopes of James were completely blasted through the imprudent interference of his favourite Buckingham, who, anxious to remove the coldness which had taken place between him and the prince of Wales, and envious of the reputation the earl of Bristol had acquired in managing affairs with Spain, proposed to Charles a romantic journey of courtship, which admirably accorded with the ardour of his youthful mind. This was to visit the continent, and pay his addresses to the infanta in person. The two chivalrous heroes set out on the 27th February 1623, Charles as a knight-errant, and Buckingham as his squire; and having passed through France in disguise, under the assumed names of Jack and Tom Smith, they arrived at Madrid on the 17th March, where they were received by the Spanish king with the most hospitable and flattering attentions. But this kindness was ill requited by the perfidy of Charles, who, after a stay of nearly eight months, returned to England, with a determination to break off the match which had been so long negociating.

This dishonourable conduct of Charles may be ascribed partly to his having fallen in love with the princess Henrietta in his way through France, and partly to the specious arguments of Buckingham, who hated the Spanish nobility, by whom he was detested in return for his impetuosity of temper and his indecent and dissolute conduct. James entered reluctantly into the views of the prince and the favourite; and the earl of Bristol, after some manœuvring on the part of government, was recalled to England, and committed a prisoner to the Tower. The king of Spain, indignant at the idea of being deceived by such shameful prevarications, ordered the infanta to lay aside the title of princess of Wales, which she had now assumed, and to think no more of Charles for her husband. This rupture led his Britannic majesty to summon a new parliament for supplies in 1624; and the Commons, who were far from being adverse to the intention of hostile operations against papists, voted a considerable though an inadequate sum. War being now declared against Spain and Austria, 6000 men were sent over to Holland to serve under the prince of Orange.

In the meantime, a negociation was entered into for a marriage between the prince of Wales and Henrietta princess of France. The English court having agreed to the proposed terms of catholic toleration, the treaty was signed at Paris on the 16th November; and nothing was now wanting but a dispensation from Rome authorising the match. In this treaty it was stipulated, that an addition should be made to the ecclesiastics in the service of the princess; that a jointure should be settled on her of 60,000 crowns a-year, and that she should be entrusted with the education of her children until they respectively arrived at 13 years of age. There was also a general promise, that the English troops should have a passage through France, and that they should receive the co-operation of the French in restoring Frederick to the palatinate. On the faith of this promise, 600 men, under count Mansfieldt, were embarked for Calais; but they were not permitted to land, in consequence of no orders having arrived from the French government for their admission. They next sailed towards Zealand, one of the united provinces of Holland, where, before disembarkation was allowed them, their numbers were so diminished and weakened by a pestilential disorder, that they were of little service in promoting the object for which they set out.

That the failure of this ill-concerted expedition had some destructive influence on the spirits and constitution of James, is not at all improbable. He was soon after seized with a tertian ague, which carried him off on the 17th March 1625, in the 59th year of his age, having reigned 22 years over England, and 58 over Scotland. In his character there was nothing great to elicit admiration, nor illustrious to command respect. His vanity was excessive; his pedantry disgusting; his generosity undistinguishing and profuse; he was learned without knowledge, ambitious without wisdom, arbitrary without power, and obstinate without firmness. Hence his parliaments received with little gratitude concessions which were rather extorted by fear than dictated by choice.

Charles I.—Charles, prince of Wales, now ascended the throne. Trained by his father to notions of absolute power, and guided, like him, by the counsels of Buckingham, he had ere long to struggle with the most determined opposition. His accession to the crown was hailed, indeed, with a general expression of joy throughout the nation; but, by the overstretching of his prerogative, and by his rash and impolitic measures, the storm which had been gathering under the former reign, continued to increase until it burst with violence on his devoted head.

Having on the 13th of June consummated his marriage with Henrietta, sister of the king of France, Charles, in order to obtain supplies for enabling him to prosecute his hostile operations against Spain and Austria, summoned a parliament on the 17th of that month. But the Commons, with whose concurrence the war had been undertaken, evinced the most insulting parsimony, by voting only L.112,000; a sum too paltry to meet the importance and urgency of the occasion. Eight ships, however, were soon fitted out; and, according to agreement, lent to Louis XIII. to be employed against the Genoese, the allies of Spain; but the sailors finding, on their arrival at Dieppe, that their real destination was to act against the Hugonots of Rochelle, refused to proceed, and, with their admiral, Pennington, who was likewise averse to the service, sailed back to the Downs. Through the misrepresentations of the artful Buckingham, by whom it was pretended, that the French king and his protestant subjects had come to terms of accommodation, the same fleet, which was a second time dispatched, again returned to England, with the full determination not to engage in a cause of which neither religion nor conscience could approve. The Commons applauded this conduct; raised more loudly their outcry against popery, and enacted laws for the stricter observance of the Sabbath; and the king perceiving, that, instead of obtaining supplies, he met with nothing but complaints, dissolved the parliament, on the ostensible ground of the plague at Oxford, where it was then assembled.

In the meantime, Charles, by forced loans from his subjects, equipped a fleet of 80 ships, and raised an army of 10,000 men, which being entrusted to the command of Lord Wimbleton, were sent against Cadiz, without being able to accomplish the object they had in view. The murmurs of the nation at such an arbitrary method of levying money, and the necessity of pecuniary grants, arising from the urgency and importance of his public engagements, induced the king, in 1626, to call a new parliament. The Commons voted him a supply, but declined passing the bill into a law till the end of the session, that they might constrain him either to renounce that supply or agree to the redress of grievances; and having proceeded to accuse Buckingham of high treason, they were severely reprimanded by the king for their animosity to the duke, the scantiness of their grant, and the manner in which it was made; and, in order to frighten them into his measures, he desired them to "remember that parliaments were altogether in his power, for their calling, sitting, and dissolution; and therefore, as he found the fruits of them good or evil, they were to continue, or not to be." Far from being intimidated, the Commons pressed their accusations against the favourite, scrutinised the different parts of the administration, and complained the more bitterly of abuses. The imprisonment of two of the members, and the dissolution of the parliament, were the consequences of this struggle.

Charles, in order to procure money, now granted a commission to compound with the catholics, so as to dispense with the penal laws to which they were subject, demanded a loan of L.100,000 from the nobility and the city of London; and ordered the counties and the capital to fit out a certain number of ships for his service. These unconstitutional expedients excited repugnance and disgust; and many individuals were thrown into prison for resisting such arbitrary impositions. Although, in general, their release was obtained on petitioning the crown, yet some insisted on their liberation, not as a favour, but as a right secured to them by the laws of their country; and Sir Thomas Darnel, Sir John Corbet, Sir Walter Earl, Sir John Hewingham, and Sir Edmund Hampden, who had their cause solemnly pleaded before the Court of King's Bench, and who, after the bail they offered was refused, were remanded to their confinement.

On the eve of these transactions, Charles, through the imprudent counsels of Buckingham, who felt indignant at an affront he had recently received from Richelieu, prime minister of France, was induced, in 1627, to engage in an unsuccessful war with that country. The duke, with a fleet of 100 sail, and an army of 7000 men, was dispatched to Rochelle to join Soubise and Rohan, who headed the protestant or Hugonot faction. But being refused admittance within the gates by the inhabitants of the town, who were ignorant of the purpose for which he went thither, he directed his course towards the isle of Rhé; and, after making an inefficient attack upon it, returned to England, having two-thirds of his army destroyed.

The failure of this enterprise, not unjustly ascribed to the rashness and misconduct of that worthless minion, tended greatly to increase the murmurs of the nation; and in the parliament, which was summoned in 1628, the Commons not only adverted in strong terms to their past grievances, but shewed a determination to secure their properties and privileges against any future invasions. Accordingly, in the famous *Petition of Right*, which was now framed, they remonstrated against all arbitrary impositions and imprisonments. The Lords offered to pass the bill, if somewhat modified; but to none of their modifications would the Commons agree. At length, in hope of gaining five subsidies, which had been voted, it was carried through the Upper House, and the royal assent was with difficulty obtained. The Commons, not yet satisfied, proceeded to attack tonnage and poundage as oppressive and unconstitutional, and to inveigh against Buckingham as the author of all their grievances; but the king, seeing there was no end to their complaints, put a stop to their deliberations by proroguing the parliament.

The subsidies thus granted were needlessly squandered in sending ineffectual succours to Rochelle. A fleet went thither, and returned without accomplishing the object of its destination; and another was ready to sail under the orders of Buckingham, when this minion of royal favour was assassinated by one Felton, a fanatical and vindictive person, who served under him as lieutenant, and had met with disappointment in his hopes of promotion. The command of the armament now devolved upon the earl of Lindsay, who, instead of affording any relief to the besieged inhabitants, arrived just in time to witness a surrender to their catholic countrymen. After the death of Buckingham, Charles began to shew more moderation in his views of power and prerogative; but the boldness and enterprise of the Commons were so far from being diminished, that they increased their clamours against tonnage and poundage, and declared those who levied, and those who paid those duties, together with Papists and Arminians, enemies of the state. Provoked by their conduct, the king, in 1629, dissolved the parliament, with the resolution never to call another; and being inadequate, from the slenderness of his means, to prosecute the war in which he was engaged, he concluded a peace with France and Spain in 1630.

Charles still continued to harass his subjects with bold invasions on their liberty. He imposed on them arbitrary duties and taxes; authorised the odious transactions of the star-chamber, and the court of high commission; and permitted Laud, bishop of London, to employ even violence, in introducing into the church new ceremonies, which the Puritans, who now composed the majority of the nation, detested as papistical and superstitions. Indeed he conducted himself as a monarch convinced that absolute authority was lodged in his hands, and that the privileges of his subjects were grants from him, which he could recal at his pleasure. In June 1633 he visited Scotland, where he was crowned with solemn pomp on the 25th of July; and on his return to London he raised Laud, an audacious zealot, and keen supporter of his absolute measures, to the archiepiscopal see of Canterbury.

Intent on accomplishing the work begun by his father, the introduction of the same rites and hierarchy into both kingdoms, Charles, scorning to convoke assemblies, in which he might meet with opposition, resolved on reforming the church of Scotland by the mere dint of his authority. For this purpose he caused to be published, in 1635, canons on ecclesiastical jurisdiction, and a liturgy differing only in a few particulars from that of the English church, and ordered that the service should be performed in St Giles', Edinburgh, on the 23d July 1637. The indignation of the Scotch was now roused, and when the dean, clothed with his surplice, entered the desk, they were thrown into an uproar, crying out, "a pope, a pope, antichrist, stone him." The bishop ascended the pulpit, and by the most gentle persuasives endeavoured to appease the tumult; but this only enraged the people the more, who, to express their determination to listen to none of his speeches, hurled their stools at his head.

Presbyterians of all ranks flocked to Edinburgh, and combined in order to resist all religious innovations. But in place of desisting from his purpose, Charles had the imprudence to push his enterprize. Opposition to his measures soon became general throughout the kingdom, and the inhabitants, who were contending for what they considered dearer to them than life, formed themselves into four Tables, the first composed of the nobility, the second of the gentry, the third of the clergy, and the fourth of burgesses. In these Tables the whole power of the country was lodged, and one of their first acts was their entering into a covenant, in which they solemnly engaged to renounce popery, to guard their religious rights from all invasions, and to unite their power for mutual defence.

Charles, perceiving the bad consequences of his despotic conduct, was now willing to make some concessions. He accordingly promised the presbyterians, by the Duke of Hamilton, that if they would retract the covenant, he would suspend the use of the liturgy in Scotland. But they replied, in a tone the most prompt, that they would sooner renounce their *baptism*; and, determined not to rest satisfied with any thing short of the entire subversion of the hierarchy, they abolished episcopacy, the high commission, the articles of Perth, the canons, and the liturgy, in an ecclesiastical assembly held at Glasgow in 1638. The whole country was now called upon to sign the covenant; and the presbyterians, thus combined, prepared to take up arms for the protection of that system of church discipline and worship to which they were attached. Hostile preparations were also made on the part of the king; and the two armies having come within sight of each other, the popular party encamping on Dunselaw, and the royalists at Berwick, agreed, in 1639, to a pacification on certain conditions, which neither intended to observe.

Charles, from the exhausted state of his finances, had contracted considerable debts; and being unable to prosecute his designs against the Scots, convoked, in 1640, after an interval of eleven years, a parliament for supplies. His demands the Commons answered only by complaints. Chiefly composed of Puritans, who were strenuous advocates for religious liberty, and far from viewing the Presbyterians as enemies to the state, they could not lend their countenance to measures which proceeded on an overstretching power, and tended to annihilate one of the dearest privileges of man. The king dissolved the parliament, and had recourse to other expedients. By grants from the clergy, loans from his ministers and courtiers, and extortions from those who were unwilling to give, he was enabled to raise a considerable army. Before his forces could be put in motion, the covenanters had advanced to the frontiers of England, and pushing southwards, they soon took possession of Newcastle. But since it was not their intention to make war against the English, they drew up an address to Charles, praying that he would advise with parliament, as to the most effectual means of alleviating their distress. Urged by the city of London, and indeed the voice of the whole nation, as well as by the want of money, the undisciplined state of the army, and their backwardness to march against the Scots, he was obliged to listen to the above petition; and on the 3d November 1640, he summoned his fifth, which has been emphatically styled the *long parliament*. The republican spirit of the Commons led them to bold and decisive measures. They resolved on a reform of the government in all its parts; heard the complaints of individuals, of cities, and of counties; and, as one of their first acts, impeached Laud and Strafford of high treason. The Lords had now cooled in their attachment to the crown, and as Charles could put little confidence in their support, he began to make concessions. He agreed that the right of imposing tonnage and poundage should be invested in the Commons, and that the parliaments to be called in future should be triennial.

Besides these concessions, the king consented to a bill for the execution of the earl of Strafford, and to another for the perpetual continuance of parliament. The courts of High Commission and the Star-chamber, and all arbitrary impositions, were abolished, and the approbation of both houses was declared necessary to give the force of a law to ecclesiastical canons. Having concluded a marriage between the Princess Mary, and William, prince of Orange, Charles set out for Scotland, only to be despoiled of that small share of authority which remained to him in that part of his dominions. A parliament was immediately called at Edinburgh, in which it was enacted that no man should be created a Scottish peer who had not a rental within the kingdom of L.500 annually. Triennial parliaments were agreed to, without whose advice and consent no officer of state should in future be appointed. The king ratified the covenant; conformed to the Presbyterian church; bestowed pensions and preferments on some of the most popular preachers; and raised the earl of Argyle to the dignity of marquis, and general Lesley, and the Lords Loudon and Lindsay to the rank of earls.

While in Scotland, Charles received intelligence of a rebellion in Ireland. He bore this news with the greatest impatience, expressed his most decided abhorrence at the conduct of the insurgents, and employed every mean in his power to suppress them. On this occasion the Irish committed massacres aggravated by every circumstance of the most wanton cruelty, sparing neither age, nor sex, nor condition. Upwards of L.40,000 of the English are said to have fallen a sacrifice to their barbarous fury.

The power of Charles was now almost annihilated; and this appeared to be the moment for fixing the bounds of royal authority, and for securing the privileges of the nation. The struggle between him and the parliament had been gradually increasing, and the greater his embarrassments were, the bolder and more daring they became. Concluding that their presumption and insolence proceeded from his facility in granting their requests, he determined, on his return from Scotland, to make an example of some of the most violent. With this purpose he brought a charge of high treason against Lord Kimbolton, and five members of the lower-house, for endeavouring to subvert the constitutional laws of the country; and, on the 3d of January 1642, he foolishly went in person to demand those commoners of their own assembly. Not finding them present, he intimated a hope that the house would send them to him, as soon as they again appeared in their places, and then retired amidst the cry of "privilege! privilege!" from all quarters. On the day following, having left the Guildhall, whither he had gone to attend a meeting of the common council, that he might justify his intentions against the accused individuals, the seditious exhortation of one of the populace, "To your tents, O Israel," saluted his ears.

Reflecting on the rashness of his conduct, the king thought of making some atonement. He promised the Commons to desist from all proceedings against the obnoxious members; and having conceded to them the tower, and agreed that Hull, Portsmouth, and the fleet, should be intrusted to persons of their nomination, he was urged also to yield to them, for an appointed time, the disposal of the army. To this last request, after some deliberation, he at length replied, in a tone of exasperated feeling, "No, not for an hour." Being no longer in safety at London, he retired to York, where the people were more loyal; and as all friendly intercourse between him and his parliament had ceased, both parties resolved on deciding the contest by force of arms. The nation was now divided between two factions; those who took the side of parliament were denominated *round-heads*, and those who supported the interest of the crown were distinguished by the name of *cavaliers*. Hostile preparations being completed, the two armies met at Edgehill, in the county of Warwick, where they engaged in the work of death, and, after some hours of hard fighting, separated, leaving on the field 5000 slain, each losing nearly an equal number. The royal troops were re-inforced with soldiers and ammunition from Holland, and though less powerful than those of the parliament, the king judged it better to maintain hostilities, than to submit to the degrading conditions on which peace was offered him. For the first twelvemonth the war was on either side attended with various success, although the balance on the whole was in favour of the sovereign. During this campaign, John Hampden, and Lord Falkland, two of the greatest men of their respective parties were killed.

In 1643, the parliament, desirous of bringing the contest to a decisive issue, requested and obtained assistance from the Scots, who were not unwilling to give facilities to a measure which had for its object or tendency the abolition of the Episcopalian, and the establishment of the Presbyterian form of worship. The commons, who detested, and never ceased to humble the bishops, avowed their intention to new-model the church of England after the example of the sister church in the north; and the Scottish parliament ordered levies of troops and of money to aid in the attainment of so desirable an object. And, as a bond of union between the two countries in promoting their mutual aims, the solemn league and covenant was framed at Edinburgh. To assist him in preparing for the ensuing campaign, and to counteract the design of the Westminster parliament, Charles summoned a parliament at Oxford, which, abstracting from some supplies which they voted, was too feeble and inefficient to promote his views, and accordingly was soon prorogued, never more to be assembled. This is the first instance of two parliaments having met and deliberated at the same time.

After several petitions for peace, and after two or three thousand women of the city of London had gone in a body to the house of Commons, remonstrating against the war, and demanding the "traitors to be given them, that they might tear them to pieces," both armies again took the field in 1664. They drew up on Marston moor, forming together an assemblage of 50,000 men; and victory, which was long doubtful, was at length decided in favour of the parliamentarians, by the skilful and successful opposition which Oliver Cromwell, who now came into notice, made to the right wing of the royalists, commanded by prince Rupert. About this time archbishop Laud, who, since the beginning of the present reign, had been confined in the tower, was condemned and executed; and almost simultaneous with his death, was the abolition of the hierarchy and the liturgic service. In the parliament the presbyterians were the most numerous, and in the army the independents predominated. The former insisted on the privilege of having regular clergy, while the latter maintained this to be unnecessary, because every individual had a right to exercise the functions of the sacred ministry. Having insinuated themselves into office, the independents began to declaim against the corruption of the generals; and Vane harangued the Commons on the complaints of these preachers, remarked that all of them had held undesignedly the same language, and concluding that this agreement of sentiment must have proceeded from the inspiration of the Holy Spirit, exhorted the assembly, for the glory of God, and honour of the country, to set aside the consideration of personal interest, and to renounce all civil and military employment. Cromwell applauded his speech, and laboured to shew how advantageous it would be to follow the counsels which it proposed. This *self-denying* ordinance having passed, the earls of Manchester and Essex, with other noblemen, resigned their commissions. Sir Thomas Fairfax was meanwhile appointed general, and, in order to retain Cromwell in office, requested his advice and assistance in making ready for the approaching campaign. By an artifice, dictated by the most consummate ambition, Cromwell was soon raised to the post of lieutenant-general under Fairfax, although, by his daring and aspiring genius, contrasted with the ease and simplicity of his superior, the whole military power fell into his hands.

In 1645 the flame of war was rekindled in Scotland. The young earl of Montrose, who, from a determined enemy, had become a zealous friend to government, attacked and defeated the earl of Tullibardine with great slaughter at Tippermuir. His prosperous enterprises were only equalled by the celerity of his marches; and when the covenanters least suspected, they were doomed, by his movements, to the rigours and ravages of war. In successive engagements he overcame Lord Elcho at Perth, Lord Burley at Aberdeen, and the earl of Argyle at Inverlochy; and, after taking the town of Dundee by assault, he vanquished Ury near Inverness, Baillie at Alford, and another body of presbyterians at Kilsyth. As a reward for his services, Charles appointed him captain-general and deputy-governor of Scotland; but he was at length arrested in his career of conquest by lieutenant-general Lesley, in a splendid victory gained at Philliphaugh.

The fate of Charles was about this time decided in the south, by the battle of Naseby. The forces on both sides were nearly equal, and although a greater number of the parliamentarians than of the royalists were slain, yet Fairfax had taken many prisoners, besides the whole of the king's artillery and ammunition. The most of the strong cities of the kingdom being now in the possession of his enemies, Charles, beset on every quarter, retreated to Oxford, from which, when Fairfax, with a victorious army, approached, he escaped in the disguise of a servant, and sought protection from the Scots, who lay encamped before Newark. But such was the infamy of their conduct that, at the end of the year 1646, they surrendered him for L.400,000 to the English, who confined him in Holdenby castle, in Northamptonshire, and secluded him from all communication with his family and friends. A difference having taken place between the army and the parliament, the former sent a party of 500 horse to seize upon his person, and carry him off to their rendezvous near Cambridge. Being afterwards brought to Hampton Court, the king, despairing of bringing Cromwell over to his views, and finding his prospects daily darkening around him, withdrew to Tichfield, and then to the isle of Wight, where he was basely apprehended by the governor, and committed a prisoner to Carisbrook castle.

A faction, called the *levellers*, had arisen in the army. These fanatics rebelled against their officers, on the pretence that among the elect the most perfect equality was designed by the Holy Spirit. By prompt and vigorous measures Cromwell reduced the mutineers to discipline and obedience, and next meditated the destruction of royal authority, by bringing the sovereign to condign punishment for maladministration. But the time for the accomplishment of this object was not yet come. The parliament was negociating with Charles for settling the calamities of the nation, although unfortunately these negociations were attended with no happy results; for, while ninety-one members had principle and firmness to resist the military power, a majority declared it to be high treason for any person to correspond with him without the permission of parliament, a declaration which actually deprived him of the throne.

During these transactions, the Scots, in 1648, sent a powerful army into England, under the Duke of Hamilton, to liberate Charles from confinement, and to reinstate him in the authority and functions of which he had been despoiled. This only prompted the more decisive energies of Cromwell, who, defeating Hamilton, obliged him to surrender, and then invaded Scotland in turn, where he fully displayed his tyrannical and oppressive disposition. In the face of the military forces, who were now flushed with success, the Commons of England still attempted to close their treaty with the king, until colonel Pride, with two regiments, blockaded the house, and excluded all the presbyterian members, allowing admission to none but the most furious and resolute of the independent party. The appropriate appellation of *Pride's* purge was bestowed on this invasion of parliament, and the few that remained, when this purifying process was ended, were designated the *rump.* The unhappy monarch was conveyed from the isle of Wight to Hurst castle, in Hampshire, whence he was conducted to London, and after undergoing a mock trial before a tribunal of villains, among whom were Fairfax, Cromwell, and Ireton, was condemned, and beheaded opposite to Whitehall, on the 30th Jan. 1649, to the astonishment and regret of the nation.

Charles was thus removed from this world of troubles, in disregard of the most pathetic letters from the queen and the prince, of the protest and abhorrence of the Scots, and of the interposition of all the courts of Europe. In his character he displayed many excellent and amiable qualities, which were unduly estimated by his rebellious parliament. But having no just knowledge of the limits of his prerogative, he was led on by his ministers and courtiers to unwarrantable extensions of power; and his zeal for episcopacy, fanned by the advice of the bigotted and impolitic Laud, was one of the principal causes of his severe misfortunes.

Commonwealth, 1649.—After the death of Charles, the house of Commons, consisting of about four score madmen, abolished the house of Lords, and announced the final subversion of the monarchy. The whole nation was thrown into confusion, and various models of a republic were conceived, according to the respective views of the existing factions. In Ireland the duke of Ormond still defended the royal cause, and Cromwell went thither to oppose him with a numerous force. The most ample success crowned the efforts of this bold and intrepid warrior; the island was reduced into a state of subjection to the commonwealth, and upwards of 40,000 Irish fled into foreign countries, to escape the horrors of a brutal ferocity. On his return to London, Cromwell received the thanks of the house for his services in Ireland. A general was now to be chosen for conducting hostile operations in Scotland, where the marquis of Argyle and his partizans had proclaimed Charles II. son of the late king, as their sovereign; and Fairfax, who was partial to the presbyterian interest, declining the office, Cromwell was appointed in his place.

Information being communicated to Charles that the Scottish parliament had offered him the crown, he was induced, chiefly by the dreadful fate of Montrose, a faithful adherent to the royal cause, to accept it on the conditions prescribed. Having, in 1650, arrived in the Frith of Forth, under the convoy of seven Dutch ships of war; he was obliged to declare himself a presbyterian, and to sign the covenant, before he was permitted to land. He was soon afterwards invested with the regal power at Scoone, amidst the rejoicings of the people; but it was not long ere he found himself considered as little more than a mere pageant of state. In the mean time general Lesley took a position between Edinburgh and Leith, and avoided all the artifice of Cromwell to bring him to an engagement. Cromwell retreated to Dunbar, and was closely followed by Lesley, when, through the imprudent interference of the presbyterian clergy, a battle commenced, which terminated in favour of the English, who were but half the number of the Scots. In pursuing the vanquished, 3000 of whom were slain, and 9000 taken prisoners, Cromwell gained possession of Edinburgh and Leith. The royal army, which had formed entrenchments at Torwood, marched, by the persuasion of Charles, into England, though only 14,000 strong, in the expectation of re-inforcements from those who were friendly to their cause. Monk being left behind with 7000 men to complete the reduction of Scotland, Cromwell proceeded after the invaders with all possible expedition, came up with them at Worcester, and, with an army of 30,000, overcame them with dreadful slaughter. The royalists were all either killed or made captives, and the king, who was obliged to fly, passed through many adventures under different disguises, embarked at Shoreham, in Sussex, and arrived in safety at Feschamp, in Normandy, in 1651.

The Bermudas, Antigua, Barbadoes, Virginia, Jersey, Guernsey, Scilly, and the Isle of Man, were reduced into subjection to the commonwealth, and Britain now became formidable to the surrounding nations. Jealous of the growing trade and prosperity of Holland, she declared war against that country, passed the famous navigation act, prohibiting foreigners from importing any merchandize not the growth of their own soil, or the produce of their own manufacture, and obtained, under admiral Blake, a degree of naval glory to which she had hitherto been a stranger. This admiral distinguished himself in different engagements with the celebrated Dutch admirals, Van Tromp and De Ruyter. The parliament, extolling the advantages which they had gained by sea, complained of the expences incurred in supporting the land forces, and insisted on the necessity of disbanding some of the troops. Cromwell, who aspired at no less than sovereign authority, saw clearly that they intended to diminish his power, and anticipated their designs by dismissing them from the house. In 1653 he entered that assembly, accompanied by 300 soldiers, and, addressing himself to the members, exclaimed, 'For shame! get you gone; give place to honester men, to those who will more faithfully discharge their trust. You are no longer a parliament; I tell you, you are no longer a parliament; the Lord has done with you.' His next parliament was composed of the lowest of the people, who believed they had received the Holy Spirit in all his plenitude, declared universities and schools of learning to be pagan institutions, and proposed adopting the Mosaic code as the foundation of the republican constitution. The Dutch ambassadors who came to England to negociate a peace, were astonished at their ignorance and fanaticism; and Cromwell, ashamed of his work, dissolved this shadow of a parliament, and in 1653 received from the army the high title of Protector of the Commonwealth.

According to the plan of the new government, it was agreed that there should be a standing army of 30,000 men; that the protector should be invested with the right of administering justice, and of concluding alliances, declaring war, or making peace; that a council, consisting of not more than twenty-one persons, nor fewer than thirteen, should be appointed; and that a parliament should be summoned every three years, and should continue sitting for five months, without adjournment, prorogation, or dissolution. The British nation now acquired the empire of the sea, and, by the skill and bravery of Blake, Holland was obliged to yield to her the honour of the flag. A peace was concluded in 1654 between the Republic and the States-general; and a new parliament being called, it was, in consequence of its proceeding to discuss the assumed authority of the usurper, dissolved before the stipulated period of its duration had expired.

Having lost the confidence of the people, the usurper endeavoured to divert their attention from himself, by directing it to foreign enterprises. With a view to promote his ambitious designs, he compelled France to withdraw her protection from the unfortunate Charles, and formed with her a treaty, the conditions of which he himself haughtily dictated, and these cardinal Mazarine was ready to accept. In 1655 he broke with Spain, destroyed her fleet, and, by a squadron under the command of Penn and Venables, deprived her of Jamaica, one of the most valuable of the West India islands.

Scotland and Ireland were now united with England in one commonwealth. A council, consisting chiefly of Englishmen, had the administration of Scotland; and to Henry, the second son of the protector, the government of Ireland was intrusted. Believing his power sufficiently established, Cromwell, in 1657, summoned a parliament, which, after the suspected members were excluded, was disposed to forward his ambitious designs. Immediately on the rights of the house of Stuart being annulled, a bill was framed and passed for tendering to him the title of king; but though to this title he had long aspired, from the dread of conspiracies, or from deference to the advice of his friends, he declined accepting it. He was then confirmed in the protectorate, endowed with a perpetual revenue, and invested with the privilege of nominating his successor. The house, which had adjourned, was again assembled, when a majority declaring against him, he instantly punished their temerity by a dissolution.

In 1658 Cromwell lent Louis XIV. a body of 6000 men, to attack the Spanish dominions in the Netherlands, shared in the glories of that signal victory which marshal Turenne gained at Dunes over the prince of Conde, and, with twenty ships of war, blocked up the port of Dunkirk, which, having capitulated, the French put into his hands as the reward of his attachment. But, notwithstanding these successes, the usurper was unhappy. Conspiracies were formed against him, and a guilty conscience disturbed his repose. The terror and agitation of his mind brought on a slow fever, which terminated in a tertian ague; and, appointing his son Richard as his successor, he expired on the 3d of September in the 59th year of his age, and the ninth of his usurpation. In the relations of private life his virtues were conspicuous; his public character, which was distinguished for inordinate ambition, was yet tempered with humanity and justice; his pretensions to religion were great, while he laughed at the sectaries whose prejudices he had flattered; and, though unlearned himself, he was not unwilling to bestow the meed of literary merit. His age was adorned with the names of Usher, Milton, Waller, Cowley, and Clarendon.

The administration of Richard was of short continuance. He had neither genius nor resolution to support the fabric which his father had raised; and in 1659, after a cabal of the principal military officers, headed by Lambert, had been formed against him, he resigned his power, to live in the obscurity of peaceful retirement. The council of war, which was now left with the supreme authority, agreed to revive the long parliament, which, after the death of Charles, Cromwell had dismissed. This assembly, amounting to about seventy members, was so contemptible, that it received the designation of the Rump parliament, which discovering a disposition to thwart the republican measures of the officers, was soon destroyed, and an intention was formed of transporting the royalists to the West Indies. Amidst the confusion and alarm that ensued, General Monk conceived and executed the secret design of restoring the monarchy. While he still affected a zeal for the commonwealth, he was prevailed upon by a gentleman of the name of Morris, who alone possessed his confidence, to allow Sir John Granville to communicate with Charles, and desire him to repair, without delay, to Holland, where he should wait for farther advice. A new parliament was called, and Monk sounding the wishes of the members as to the settlement of the state, and finding them favourable to his views, desired the speaker to inform them, that one Sir John Granville was at the door of the house, with a message from the king. This message, which offered a general amnesty, promised liberty of conscience, and assured the soldiers of their arrears and the continuance of their present pay, called forth from all quarters bursts of rejoicing and applause.

Charles II. 1660.—Charles having landed at Dover, in a fleet which had been sent under Admiral Montague to bring him over to England, arrived in London on the 29th of May 1660, amidst the acclamations of the people. The contrast between his present state and his former adversities, combined with his manly figure and affability of character, excited universal interest in his favour. He was happy in the choice of his ministers; the earl of Clarendon was chancellor; the duke of Ormond, steward of the household; the earl of Southampton, high treasurer; and Sir Edward Nicholas, secretary of state. Two of the immediate instruments of his restoration, general Monk and admiral Montague, were honoured with marks of his gratitude and regard—the former was created duke of Albemarle, and the latter earl of Sandwich. Of the regicides, ten suffered with the confidence of martyrs; and the bodies of Cromwell, Ireton, and Bradshaw, were dragged from their graves to the place of execution, and doomed to sepulture under the gibbet on which they were hung. The parliament, all submissive and respectful, voted subsidies to the king, and fixed his revenue for all charges at the sum of L.1,200,000 annually; a revenue which far exceeded what any sovereign of England had before possessed. By the advice of Clarendon he disbanded all the troops, with the exception of about 5,000 men, who composed the first standing army under the monarchy which the annals of the kingdom record. He then dissolved the parliament with a most gracious speech.

Through the instigation of Clarendon, Charles, forgetting the compact on which he was recalled, and declaring that "Presbyterianism was not a religion for a gentleman," resolved, in 1661, to restore Episcopacy in Scotland. The Scottish parliament, equally compliant with that of England, granted him a revenue of L.40,000 for life, annulled the covenant as treasonable, and abolished every act which restricted the authority of the crown. Alarmed at these transactions, the presbyterians commissioned James Sharpe, one of their ministers, to manage their interests with the king; but this perfidious man abandoned their cause, and, as a reward for his treachery, was raised to the dignity of archbishop of St Andrews. The covenanters soon felt the vengeance of Charles; and the marquis of Argyle and the reverend James Guthrie, having undergone the most iniquitous trials, were condemned and executed, while others were committed to prison or consigned to banishment. Prelacy was sanctioned as the national religion,—the oath of supremacy and allegiance was enjoined,—and the recusant clergy were obliged to vacate their charges. In England an ecclesiastical transformation had likewise taken place; and the church being brought back to the state in which it existed previously to its change under the usurpation, an act of uniformity was passed in 1662, requiring the re-ordination of such ministers as had not been episcopally ordained, and their assent to every thing contained in the Book of Common Prayer, on the pain of ejection from their livings. Those who refused compliance with this act, and they amounted to 2000, were distinguished by the appellation of *non-conformists*.

About this time Charles married Catharine, the infanta of Portugal, who, besides the two fortresses of Tangier and Bombay, brought him L.500,000 as her dowry. Still, however, the revenue of the crown was, by his prodigalities, too slender to support the charges of the state; and, immersed in debt, he resolved to sell Dunkirk, which he accordingly made over to France for L.400,000. Induced by his prepossessions in favour of popery, he issued a declaration for softening the rigorous act of uniformity, and for granting a general indulgence. But his designs could not escape the penetration of parliament; and, in 1663, both houses concurring in a remonstrance against catholics, constrained him to drop his project of toleration. Four subsidies, the last taxes levied in this manner, were now voted him by the Commons.

Scotland was at present groaning under the yoke of prelacy. The presbyterian clergy in the southern and western parts of the kingdom were excluded from their pulpits; and, in consequence of this unprincipled exertion of power, the people, who could not in conscience attend the ministration of the new incumbents, were reduced to the necessity of going many miles to perform the public duties of religion, and ultimately of assembling in the fields for that purpose. As non-conformists, the covenanters were exposed to the exaction of heavy fines; and such was their determined adherence to their own system, that they were dragged with equal facility to church and to prison. In 1664, the inquisitorial and infamous court of High Commission was erected, an act was passed for suppressing conventicles, or private meetings for the worship of God; and, soon after, another followed for prohibiting the extension of charity to the suffering pastors who had been ejected from their livings. To shew the inconsistency of the instruments of regal oppression, it may be observed, that when the lord high commissioner Glencairn, and other persons of distinction and influence, apprehended the approach of dissolution, they wished to be attended in their last moments by presbyterian clergymen; a fact which led the duke of York to remark, "That he believed all Scotsmen, be what they would in their life, were presbyterians at their death."

The English parliament, prompted by a feeling of loyalty, repealed the triennial act; and the Commons, jealous of the flourishing commerce of Holland, persuaded Charles, by the offer of subsidies, which his extravagant dissipation had rendered indispensible, to declare war against that country. Under Sir Robert Holmes, a squadron of twenty ships was secretly dispatched, which deprived the Dutch of their African territories and of Nova Belgia, the present New York, in America. But about the beginning of the next year (1665), the famous De Ruyter recovered to the United Provinces their possessions on the coast of Guinea, and then retaliated on the English, by expelling them from some of their old settlements. Maritime hostilities immediately commenced between the grand fleets of the two nations; and different bloody engagements were terminated with various success, displaying the consummate skill and bravery of the contending admirals. During these operations, about 90,000 of the inhabitants of London were swept away by a plague; and in September 1666, a fire broke out, which, raging for three days, laid in ashes the greater part of the city! These tremendous visitations, the latter of which popular prejudice ascribed to the catholics, were the means of giving a check to the contest with Holland. A diminution of the resources granted by parliament, constrained the king to think of pacific measures. But De Wit, pensioner and governor of the Dutch republic, protracted the negociation, in the hope of humbling the English for their unprovoked and unjust aggressions; and taking advantage of the moment, he sent De Ruyter with a fleet, who sailed up the Thames, as far as Upnore castle, destroying the shipping in his passage, and then, not finding himself supported by the French as he expected, returned, spreading alarm along the coasts. England was at length relieved of this dangerous enemy, by a peace which was signed at Breda on the 10th of July 1667. To arrest the conquests of France, now begun in the Netherlands, a triple alliance, which soon after led to the treaty of Aix-la-Chapelle, was formed in 1668 between Holland, England, and Sweden.

In Scotland the presbyterians were still oppressed. The proceedings of the ecclesiastical commission were carried on with unabated rigour; and the consciences of the people were tried before the tribunal

Civil history.

of arbitrary and unwarrantable power. Even the crafty and vindictive Lauderdale, who had superseded the ferocious Middleton, in the administration of Scottish affairs, advised the king to more lenient steps; but this abatement of tyranny came too late to allay the irritation which harsher conduct had produced. The covenanters, having taken up arms, were attacked and defeated near the Pentland hills, by general Dalziel. Scenes of barbarity ensued, sufficient to appal the stoutest feelings of the human mind; imprisonment, banishment, and death, accompanied with every refinement of cruelty, were the punishments to which the vanquished were doomed. A young preacher, Hugh M'Kail, after suffering the excruciating torture of the boot, expired on the scaffold, uttering these sublime and pathetic accents:—"Farewell, father and mother, friends and relations! farewell thou sun, moon, and stars! farewell, world and time! farewell, weak and frail body! Welcome eternity! welcome angels and saints! welcome Saviour of the world! and welcome God, the judge of all!" The violence of that persecuting spirit, for which Sharpe was distinguished subsequently to the affair at Pentland, had rendered him so odious to the public, that one day, while passing in his coach down the High Street of Edinburgh, an unsuccessful attempt was made upon his life. This vacillating and unprincipled bishop, as if acquainted with the secret designs of Charles for establishing popery in the nation, was of opinion that the presbyterians were more dangerous to his majesty's government than the catholics, who were at this time (1671) considerably increased, and that their meetings should be watched with a jealousy and a rigour which surpassed all former severity against them.

The king, in order to render himself independent of parliament, and to overturn the protestant religion, reposed all his confidence in Clifford, Ashley, Buckingham, Arlington, and Lauderdale; and from the five letters which begin their names, the junto, composed of these ministers, was called the *Cabal*. By the advice of this junto, he signed an agreement with Louis XIV. for destroying the Dutch republic; and it was farther stipulated that Charles should receive from France L.200,000 annually, and assistance in accomplishing his project in favour of the Roman faith. The Commons, deluded by the assurance that such supplies were necessary to maintain the triple alliance into which he had lately entered, voted him between L.200,000 and L.300,000; but having squandered this money by his thoughtless extravagance, and dreading the result of another application to parliament, who had already discovered his object, he seized the issues of the Exchequer, to the ruin of the commercial interest. James, duke of York, avowed his conversion to popery; a proclamation of indulgence to liberty of conscience was made; and on the 17th of March 1672, war was declared against Holland, on the most frivolous pretences. During this war several bloody but indecisive engagements took place by sea, although by land the combined powers were more successful. The terms offered to the Dutch, who earnestly sued for peace, were, from their threatening the very dissolution of the republic, too insulting to be accepted. To the popular fury now excited by despair, De Wit fell a sacrifice; and the administration of affairs devolved on the prince of Orange. With a view to bring him over to their interest, the allied sovereigns held out to him the most splendid offers. But he spurned the proffered boon with a noble disdain; and when Buckingham urged him by the destruction which a refusal would bring upon the commonwealth, he replied, in a high tone of patriotic feeling: "There is one certain means by which I can be sure never to see my country's ruin, I will die in the last ditch."

Civil history.

The oppression of the Dutch protestants excited the murmurs of the British nation; and Charles, to justify his conduct, or to sound his subjects more fully in reference to the war, summoned a parliament in the beginning of 1673. Indignant at the dispensing power which he had assumed in matters of religion, they opposed his declaration of indulgence, and passed the *test act*, enjoining upon all who fill offices of trust to take the oath of allegiance and supremacy, to receive the sacrament as administered in the established church, and to abjure the popish doctrine of transubstantiation. After an adjournment, parliament again met in October, when they remonstrated against the marriage negociating between the duke of York and the catholic duchess of Modena; voted the standing army a grievance; and avowed their determination to grant no more supplies for maintaining hostilities with Holland. In order to avoid altercations, and to afford the duke time to conclude the match, they were dismissed; and when re-assembled in 1674, the king found their sentiments regarding the subjects of former discussion unaltered; and he signed a separate peace with the United Provinces, on terms advantageous to Britain.

During the four years immediately subsequent to this treaty, nothing of any importance occurred. This period was chiefly employed with attempts on the part of Charles to obtain money from France, and with fruitless endeavours to deceive his people by false promises and professions; and, on the part of the Commons, with addresses against the duke's marriage, already celebrated by proxy; against standing armies, and other national grievances. Wishing in vain to recover the popularity which he had lost, the king, in November 1667, gave in marriage the princess Mary, his brother's eldest daughter, to William, prince of Orange.

In 1678, the attention of the nation was arrested by the rumour of a popish plot. The pope, it was pretended, had, in consequence of the heresy of England, Scotland, and Ireland, assumed the sovereignty of these kingdoms, and had delegated his authority to the jesuits, who were to take possession of them, after having cut off, by an universal massacre, the prince and his protestant subjects. But although Titus Oates, and the other obscure and incredible reporters of this plot, could produce no proof of its existence, their depositions gained weight in parliament, and spread alarm throughout the island; and Charles was obliged to adopt, with apparent approbation, measures against a conspiracy which he did not believe. The duke of York became every day more odious; and the minds of the Commons were prepared for a revolt, when the king, in 1679, dissolved the parliament, which, including its various sessions, had continued seventeen years. A new one was soon after called, which evinced the same determined opposition to popery and arbitrary proceedings, as the former had done. The standing army and king's guards were declared illegal: the *habeas corpus* act, that great bulwark of the British subject against oppressive imprisonments, was passed; and a bill for excluding the duke of York from the throne, was carried by a majority of 79 in the house of Commons, but was resisted and lost in the house of Lords.

Informed of an indisposition of the king, James returned from Brussels, whither, from prudential motives suggested by his majesty, he had retired during these transactions; and jealous of the popularity which the duke of Monmouth, natural son of Charles, had acquired, he visited Scotland, with the secret, though not ostensible object of strengthening his interest in that kingdom. Here the presbyterians were meanwhile subjected to increasing severities. The bloody Lauderdale exerted all his power to suppress conventicles; and, on the refusal of the landholders in the western counties to give bonds, engaging them, under heavy penalties, to prevent the assembling and entertaining of preachers on their estates, he let loose among them 6000 lawless Highlanders, to threaten, and pillage, and destroy. About this time an instrument of infamous oppression, archbishop Sharpe, came to his end. He was dispatched on Magusmuir by a small party of presbyterians, while they way-laid one Carmichael, whom they also detested for his cruelty. The crime of perpetrating this nefarious deed was charged upon the whole body of covenanters, who were in consequence exposed to the most violent persecution. Driven to desperation, they again took up arms, and defeated Graham of Claverhouse, who attacked them on Loudonhill. With a force, augmented by thousands who now flocked to their standard, they immediately marched to Hamilton; and expelling the royal troops from Glasgow, made themselves masters of that town, where they issued a proclamation, declaring that they fought against the king's supremacy, and against all popish and prelatical impositions. The duke of Monmouth engaged the insurgents at Bothwell bridge, and, their ammunition failing, dispersed them with great loss, killing 700, and taking 1,200 prisoners. To these captives, whom the humanity of Monmouth preserved from massacre, pardon was offered on terms which few of them accepted; and to punish their obstinacy, 300 of them were shipped for Barbadoes, and unfortunately perished on the voyage. An act of indemnity was soon passed, which, through the barbarous artifice of Lauderdale, afforded them but little protection.

Having dissolved a parliament which was keen in its support of the popular interest, Charles was assailed with numerous addresses from his subjects, some clamorously praying for a new election, and others disapproving of these prayers, and expressing their respectful submission to the authority of the crown. Hence, the opposite parties were distinguished by the names of *Petitioners* and *Abhorrers;* to the former of whom was also applied, by way of reproach, the appellation of *Whigs,* and to the latter that of *Tories.* A parliament was at length summoned in October 1680, which was far from displaying an accommodating spirit. The Commons declaimed against the abhorrers, and continued committing them to prison, till one Stowel checked their arbitrary proceedings by his manly resistance. Mortified by a second rejection of the exclusion bill in the house of Lords, they resolved to withhold all supply whatever from the king, and to make those who should in future advance him money on any part of his revenue, responsible for their conduct. Charles, finding them invincible in their purpose, dismissed them by a dissolution.

With the view of humbling the inhabitants of London by a mark of neglect, and in the hope, perhaps, of managing the Commons when removed to a distance from a place where the spirit of faction prevailed, Charles summoned a parliament to meet at Oxford in 1681. Here, however, he was as unsuccessful as he had hitherto been, for they even surpassed their predecessors in the acrimony with which they urged the bill of exclusion, and refused listening to a proposal for banishing the duke of York 500 miles from England, and for leaving him, on the death of his majesty, with the bare title of king, while the next heir should be constituted regent with regal power. Availing himself of a debate, concerning one Fitzharris, an Irish catholic, who pretended to divulge the secret of another popish plot, Charles dissolved the last parliament he was determined ever to call. On this sudden and unforeseen measure, so confounding to the Commons, addresses and congratulations poured in to him from all quarters. Maxims the most favourable to monarchy pervaded the nation; and such was the quick transition from one extreme to another, that the people rushed into that very slavery, against which they had so long struggled.

The severity of the king's temper now appeared, in that despotic authority with which he guided the reins of government. Through the evil counsels of his brother, he spread terror over the island; and the privileges of his subjects were no longer free from the grasp of oppression. The city of London was deprived of its charter, which, in 1683, was restored on the humbling condition of conceding the right of nominating its magistrates to the crown. Alarmed at this violent infraction of liberty, the other corporations in England also delivered up their charters, and, before they could recover them, were obliged to pay large sums of money, and to submit to certain restrictions. Many conspiracies were now formed, detected, and punished; in some of which the duke of Monmouth, with several associates of rank and influence, was concerned. Although the general object of the conspirators was to oppose the succession of James to the throne, different views were entertained as to the subsequent settlement of the kingdom. Monmouth aspired to the sovereignty himself; Lord Russel and John Hampden wished a redress of grievances; and Lord Essex and Algernon Sidney contended for a republic.

In the mean-time, distresses in the north were unabated. The acts against conventicles were again put in force, and the duke of York, who succeeded

Lauderdale in the management of Scottish affairs, treated the presbyterians with a rigour and cruelty, revolting to every principle of humanity and justice. At his request, a test was passed for enjoining the king's supremacy; and because the earl of Argyle, who from his youth had been distinguished for his loyalty, took this test with an innocent explanation, he was condemned for high treason to suffer the forfeiture and punishment of a traitor. But before the execution of the sentence he escaped from prison, and fled to Holland. About this time, one Cameron, the leader of a religious party bearing his name, publicly excommunicated Charles for his breach of the covenant, but was soon after slain at Airs-moss, in an action with the royal troops. James having returned to London on a visit to the king, the administration devolved on the earl of Aberdeen and the duke of Queensberry,—two men whose characters were as despicable as their abilities were weak. Under them, upwards of 200 persons were outlawed, on pretence of holding intercourse with rebels; and every exertion was made to ensnare people living peaceably in their own houses, by extorting from them an avowal of their private sentiments. To them the following questions were put: "Will you renounce the covenant? Was the rising at Bothwell rebellion? Was the killing of archbishop Sharpe murder?" If they refused to answer these questions, they were exposed to torture, to banishment, and to death. Even women expired on the gibbet, or were drowned at the stake.

In order to increase his growing popularity, Charles, in 1684, gave in marriage his niece, lady Anne, to prince George of Denmark. Yet though he was daily rising in the public opinion, the violence of his brother's temper, and the severity of his administration, occasioned him great uneasiness; so that he deemed it expedient to meditate a new plan of government. Accordingly, he proposed to dismiss all the ministers obnoxious to the people, and even thought of calling a parliament, when he was suddenly attacked with a disease, resembling an apoplexy. After languishing a few days, he died on the 6th of February 1685, in the 59th year of his age, and, calculating from the time of his restoration, in the 25th year of his reign. During his illness, he shewed great indifference to the established clergy, and a strong predilection for catholic priests. From the hands of the latter he received the sacrament, and thus departed in communion with the church of Rome. In his character as a man, he had a lively wit and polite manners, associated with a criminal addiction to pleasures, and a total disregard of all religion; and as a sovereign, he was led astray by high ideas of prerogative, was lavish of the public treasures, and jealous of the liberty of his subjects.

James II.—Under the title of James II. the duke of York acceded to the crown, without opposition. Having summoned a privy council, he declared his intention to maintain the constitution in church and state; but his conduct soon evinced the insincerity of his professions. He went publicly to mass, dispatched one Caryl to Rome with expressions of his submission to the pope, and claimed, as a matter of right, all the customs and the greatest part of the excise, which had been granted during life to the late king. Finding it necessary to assemble a parliament, he renewed his promise to support the protestant religion, and requested and obtained the same settled revenue which his brother had enjoyed. In his speech, he observed, "There is indeed, one popular argument against complying with my demand. Men may think, that by feeding me from time to time with such supplies as they think convenient, they will better secure frequent meetings of parliament; but as this is the first time I speak to you from the throne, I must plainly tell you, that such an expedient will be highly improper to employ with me, and that the best way to engage me to meet you often, is always to use me well."

The Scottish parliament was equally compliant with the English; and the authority of James was absolute and undisputed, when Monmouth, who had retired to the continent, where he was still pursued by the vengeance of his uncle, made a descent upon England, with scarcely a hundred men. But such was the popularity of the duke, aided, doubtless, by the prevalent aversion to popery, that in four days, 2000 flocked to his standard, and, in a short time, the number increased to 6000. After being proclaimed at Bridgewater, Wells, and Frone, he was attacked by Feversham at Sedgemore; and chiefly through the cowardice of lord Grey, to whom he entrusted the command of his cavalry, he was overcome with great slaughter. Monmouth, flying from the field, until his horse sunk under him, was found in a ditch, concealed among ferns, with raw pease in his pocket. He wept on being seized; petitioned in the most submissive terms for his life; and even signed a paper, presented to him by the king, declaring his own illegitimacy. Yet the relentless tyrant refused to pardon him; and amidst the silent tears of the people, who attended him to the scaffold, he met his fate with the greatest fortitude. By the brutal severity of colonel Kirke and judge Jefferies, the most savage butcheries were committed on his adherents.

Returning from Holland, whither he had effected his escape under the former reign, the earl of Argyle seconded the views of Monmouth in Scotland. But his small army, amounting to 2,500 men, which he with difficulty raised, fell away on the appearance of the royal troops; and he himself was taken prisoner near Renfrew, while standing up to the neck in a pool of water. The earl was carried to Edinburgh, where, with a serene and manly spirit, he publicly suffered execution. Every possible outrage assailed those who favoured his rebellion, and his estates were made the scenes of devastation, of misery, and of death.

James, emboldened by the prosperity which at present attended him, began to speak and act as an absolute monarch. Hitherto he had covertly protected the catholics, while the parliament dared not to penetrate his designs, but now openly avowing their cause, in attempting to set aside the test, both houses, convinced of the danger which threatened the established church and the protestant religion, resisted his unwarrantable measures. They demanded, whether, in virtue of his prerogatives, he could dispense with the laws? a question which occupied the public mind, awakened the national hatred of popery, and called forth harangues from the pulpit, by no means calculated to allay the fears of the people. Irritated by this opposition, he first prorogued and then dissolved the parliament.

The revocation of the edict of Nantes by Louis XIV. in 1686, drove into England nearly 50,000 French protestants, who, as living monuments of oppression, spread the terrors of Romish superstition over the country. At this time, an arbitrary tribunal, resembling the commission court of Elizabeth, was established, which decided in favour of the king's dispensing power, and suspended Compton, bishop of London, for suffering a clergyman to preach with impunity against the church of Rome. Four catholic lords were admitted into the privy council; and James, influenced by the queen, and Father Peters, his confessor, displayed an indiscreet and precipitate zeal in making converts to his own opinions.

In 1687, the king issued a proclamation, offering liberty of conscience to all denominations of Christians under his government; and he tried in vain to facilitate an acquiesence in this edict, by laying a bait before the non-conformists. He next endeavoured to reconcile his dominions to the catholic see. With this view he dispatched the earl of Castlemaine, as his ambassador extraordinary to Rome; a step not less pleasing to his subjects, than to the Pope himself, who could by no means approve of the rashness and imprudence of a scheme, which was likely to terminate in the most fatal consequences. The ambassador, accordingly, was coolly received; and Innocent XI. deemed it sufficient merely to send his nuncio to London, to consecrate bishops, who should publish their pastoral instructions, with the permission of the king.

James now made an unsuccessful attempt to open the universities to catholics; and the means he employed for the accomplishment of this object had excited a ferment, when he issued a second declaration of indulgence, and ordered it to be read in all the churches, at the conclusion of divine service. But the clergy, considering this order as a violence done to their consciences, as well as a manifest infringement on the laws of the nation, six bishops drew up a remonstrance against it to the king, which being construed into a seditious libel, these venerable men were committed to the tower, to stand their trial. The jury pronounced them "not guilty," and Westminster hall, and the whole city, were filled with the loudest acclamations of joy.

Since the revolt of Monmouth, the royal troops had been encamped, during the summer, on Hounslow-heath. James, being present on the spot, was at dinner in Lord Feversham's tent, when his ears were suddenly assailed with shouts from without. On inquiring into the cause, he was told by Feversham, that "it was nothing but the soldiers rejoicing for the acquital of the bishops." His majesty replied, "Call you that nothing? but so much the worse for them." Although sensible, as he must have already been, that he stood alone with a small handful of catholics against the people, and even against his own army, he was too blind and infatuated to desist from his purpose. Judging this the proper crisis for breaking the silence, which he had hitherto observed, William, prince of Orange, avowed his determination to oppose the repealing of the penal statutes, without the consent of parliament,—a consent which he knew could not be obtained. Such an interference, while it encouraged the protestants to persevere in stemming the tide of popery, gave grievous offence to James, and furnished him with a pretext for meditating hostilities with the United Provinces. Numerous individuals leaving the country, offered their services to William, and requested his prompt and active exertions to save the nation from the ruin which threatened its civil and ecclesiastical constitution. Whigs and Tories, churchmen and dissenters, forgetting their mutual animosities, joined in this patriotic request; and the prince of Orange, having made every necessary provision and arrangement, waited a favourable opportunity of sailing for England. Through the medium of France, James was informed of the secret designs of his son-in-law; but he refused to credit the information, until it was too late,—until all the concessions, which he was now disposed to make, were of no avail.

During these transactions, the cause of popery was gaining ground in Scotland. The laws against papists were superseded by the privy council; the earl of Perth, a convert from protestantism, opened a chapel for the celebration of mass, at Holyrood-house; and the unprincipled among the bishops, who were ambitious of the royal favour, forsook the reformed church to embrace the catholic faith. Amidst this relapse and alienation from genuine Christianity, the presbyterians conducted themselves with a consistency and firmness, which called down the vengeance of government. The amiable Renwick and others were executed; and such was the general abhorrence of the Romish religion, that a correspondence was renewed and carried on with the prince of Orange, as the only means of obtaining a deliverance from the tyranny and superstition, under which they groaned.

William, no longer concealing his projected invasion, published a manifesto, in which, after detailing the abuses which had armed the people against the government of James, he declared his intention of passing with an army into England, to call a free parliament, and to provide for the security of the nation. He embarked at Helvoetsluys with a fleet of about 500 vessels, and a force of 14,000 men, and landed at Torbay on the 5th of November 1688. At first the malecontents, in whose remembrance the executions, which followed Monmouth's rebellion, were still recent, kept a strict neutrality; in so much, that the prince, despairing of success, thought of returning to Holland. But while thus deliberating, he was joined by several persons of distinction and influence; and ere long the whole country, including many officers and regiments of royal troops, flocked to his standard. Even Lord Churchhill, afterwards duke of Marlborough, who was indebted for all his fortune to the king's bounty, went over to William, carrying along with him, among others, the duke of Grafton and colonel Berkley. Prince George of Denmark, together with the princess Anne, to

2

whom he was married, also espoused the same cause; and James, on hearing the news of their defection, exclaimed, in an agony of grief, "God help me, my own children have forsaken me!" In now attempting to leave the kingdom, he was arrested and brought back to Whitehall; and being permitted to retire to Rochester, he escaped from his confinement, and went to France, whither the queen, with the infant prince, had gone before him. Thus terminated the reign of a king, who, though respectable in domestic life, and frugal of the public money, disregarded the civil and religious constitution of the country, and evinced a blind and intolerable zeal for the catholic church.

William III.—In January 1689, a parliament, or rather a convention, was summoned. By this convention, after much debating, the throne was declared vacant, in consequence of the flight of the king; the royal prerogative was reduced to its just bounds; the privileges of the nation were determined; and the crown was given to William and Mary.

On the abdication of James, the people of Scotland, with a few exceptions, rose in arms against the old government; the episcopal clergy in the south-western districts were carried in mock procession through their parishes; the students of the university of Glasgow burned the effigy of the pope; and those of the university of Edinburgh, aided by apprentices and the more zealous citizens, rifled the chapel of Holyroodhouse, and committed the images and books to the flames. A convention, called on the 22d of March, made a tender of the Scottish crown to the prince and princess of Orange. Many of the forfeited honours and estates were restored; popery indignantly proscribed; and presbyterianism, with all its claims, re-established. The revolution, thus accomplished, forms an important era in the annals of the united kingdoms.

Against Louis XIV. long dreaded as the scourge of Europe, a powerful confederacy had, through the influence of William, been lately formed at Augsburg. To this confederacy Britain now acceded; but the French monarch, far from being dispirited by such a combination, was resolved to assist James in regaining the throne which he had abdicated. Being, accordingly, supplied with a fleet for the invasion of Ireland, where his authority was still acknowledged, the ex-king, with some French officers and about 1200 British subjects, landed on the island, to be joined by the earl of Tyrconnel with an army of nearly 40,000 men. He soon proceeded to besiege the town of Londonderry, the only place in the kingdom which refused him submission; but he was at length obliged to abandon the siege with precipitation and great loss. The cause of James was at the same time undertaken in Scotland, by viscount Dundee, who, having collected a considerable force, was met, at the pass of Killicrankie in Athol, by a body of William's troops, under the command of general Mackay. A desperate and bloody engagement ensued; and the fortune of the day, which first inclined to the side of the Highlanders, who made a dash upon their enemies sword in hand, ultimately decided in favour of the English.

In Ireland the two hostile armies came in sight of each other on the opposite banks of the Boyne. William now appeared at the head of his own men; and as he was examining the ground along the side of the river, a shot from one of the enemy's cannon grazed his shoulder, and killed several of his followers. At six o'clock, next morning, his troops crossed in three different places; a furious battle commenced; the Irish fled with precipitation, and the protestants gained a signal victory. James kept at a distance from the field; while William, taking an active part in the scene, contributed to the success and glory of the combat. The campaign of 1691 determined the fate of Ireland. Having sustained a complete defeat at Aughrim, the Irish retreated to Limerick, where, on their capitulating, hostilities ceased. By this capitulation, the catholics were allowed the same religious liberties, which they enjoyed under Charles II. and the dissatisfied were permitted to remove with all their effects to any country but that of Britain. Accordingly, 14,000 of the inflexible adherents of James went over into France.

Meanwhile, Scotland witnessed a barbarous and inhuman transaction. It was deemed necessary, for the total suppression of the disorders in the Highlands, to require of all the clans, which had risen in Argyle's rebellion, the oath of allegiance to William's government. Macdonald of Glencoe, the last that stood out, was prevented by a storm from taking this oath before the sheriff of Argyleshire, till the specified period had expired. But although the sheriff yielded to his entreaties, and accepted the oath, which he instantly transmitted to the privy council, the fact of Macdonald's submission was basely concealed; and being misrepresented by the earls of Stair and Braidalbin, captain Campbell of Glenlyon was employed to put them all to the sword. The consequence was, that after entertaining, for fifteen days, with great hospitality, Campbell and his men, who pretended to have come as friends, Macdonald and the unsuspecting inhabitants of the vale of Glencoe were doomed to destruction, in February 1691; neither youth, nor age, nor sex escaped, except by a timely flight to the mountains. William immediately instituted an enquiry into the cause of this shocking barbarity, and the guilt being traced to Stair and Braidalbin, the former was dismissed, and the latter suffered a temporary disgrace.

James, having completely failed in Ireland, now rested his hopes on the exertions of Louis; and the French king, projecting an invasion of England, appointed admiral Tourville, with 63 ships of the line, to favour the descent of James, with a considerable force under his command. But admiral Russel, being dispatched with 99 ships of the line to oppose this armament, the two fleets engaged off La Hogue on the 19th of May 1692, and, after an action of ten hours, the English were victorious. The French lost fifteen large vessels, together with the empire of the sea, which they had recently obtained. From this time to his death, a period of about seven years, James continued as a pensioner of Louis at St Germains. Respecting his unfortunate situation, Le Tellier, archbishop of Rheims, said with justice, though rather with levity—"There is a simpleton has given three kingdoms for a mass."

William had to contend with the house of Commons, and to submit to restraints on his authority. They examined into the uses to which he devoted the money they had given him; and, before they would vote him new supplies, they, in 1694, urged and obtained his consent to a bill, for limiting the duration of parliament to three years. This limitation was judged necessary for the preservation of liberty, and the preventing of corruption, because a longer continuance had rendered it an object to influence the elections by purchasing votes. In 1696, a conspiracy which had been formed against the king, was discovered; and on this occasion both houses evincing a zeal for his safety, entered into an association for the defence of his person, and the support of his government.

The war, on the continent, was at length terminated in 1697, by the treaty of Ryswick, in which France acknowledged William as the legitimate sovereign of Great Britain and Ireland, and promised to give him no more trouble, either directly or indirectly. To carry on this war, immense sums of money had been voted by parliament. But the nation was now tired of oppressive taxes; and when the king demanded a fresh subsidy for the discharge of debts, and the maintenance of the army, the Commons resolved, without a division, that none of the land forces, raised since September 1680, should be retained. This parliament was dissolved, and another called; and William having as yet made no military reductions, an act was passed, ordering all the troops in England and Wales, with the exception of 7,000, to be disbanded, by a fixed day. From his partiality to the Dutch, he had become rather unpopular; and it was the wish of the nation, that no foreigner, but George prince of Denmark, should be admitted into his councils.

A new parliament, called in 1700, was more compliant. They assured the king that they were ready to co-operate with him in the adoption of any measure, which had for its object the interest of the protestant religion, or the safety and advantage of the nation. And to prevent the restoration of the exiled family, they enacted that the crown, on the event of Anne's dying without issue, should devolve on Sophia of Hanover.

On the 16th of September, James died at St Germains, and Louis declared his son, the pretended prince of Wales, king of Great Britain, under the title of James III. Ere long, however, the French monarch saw reason to repent of a step, which excited the indignation of the English, without serving the prince. The present state of the public feelings offered to William a favourable opportunity, for obtaining supplies. He represented the conduct of Louis as an attempt which threatened the interest of the protestant religion, the tranquillity of the people, and the liberty of the nation; he exaggerated the power of the house of Bourbon, which after acceding, in terms of a late treaty, to the throne of Spain, would endeavour to establish a popish sovereign upon that of England; he held out, that commerce would be ruined by the union of the French and Spanish monarchies, unless some effectual measures were adopted, to humble them before they had time to combine their forces; in a word, he shewed that the conquests, to which America might fall an easy prey, would be sufficient to counterbalance the expences of the war.

Both houses of parliament entered cordially into his views; and, resolving that no peace should be concluded with France, until reparation was made for the insult she had offered, in declaring the pretended prince of Wales king of England, they granted a large supply, and ordained that 40,000 men should be raised, for hostile operations on the continent. The season for commencing the approaching campaign arrived, when William was taken dangerously ill. His constitution had been for some time declining, but a fracture of his collar-bone, occasioned by a fall from his horse while hunting, brought on a fever and diarrhœa, which ended his days on the 16th of March 1702, in the 14th year of his reign, and 52d of his age; having survived for a few years his amiable consort, who had been carried off by the small-pox.

In the reign of William, the system of borrowing money on remote funds was introduced; a standing army was for the first time sanctioned by parliament; and the bank of England, together with the salt and stamp offices, was established. His character has been differently represented, in being either darkened by prejudice, or heightened by partiality. Candour, however, must admit, that although a zealous presbyterian, he was a public-spirited monarch, a brave general, and an able statesman.

Anne.—On the death of William, Anne, the only surviving daughter of James II. ascended the throne of Britain, conformably to the order of succession established by parliament. Determined to follow up the intentions of her predecessor, she, with the approbation of the Commons, declared war against France. This declaration was seconded by a similar one on the part of Holland and Germany; and Louis, indignant at such a combination, could not help expressing his contempt of the United Provinces. "As for these gentlemen pedlars, the Dutch," said he, "they shall one day repent their insolence and presumption, in declaring war against one, whose power they had formerly felt and dreaded."

The famous duke of Marlborough, who enjoyed the confidence of Anne, was appointed generalissimo of the allied forces of England and Holland; and every preparation was made for the ensuing campaign. With a force of 60,000 men, he took the field in July, and obtained some considerable advantages in Flanders, over the French army, commanded by the duke of Burgundy and marshal de Boufflers. While the enemy retired before him, Spanish Guelderland was left exposed, and the towns of Werk, Venlo, Ruremonde, and Liege were obliged to surrender. During these transactions on land, achievements no less signal were accomplished by sea. The combined fleets of England and Holland attacked a French squadron, as they were sailing into the port of Vigo, with the Spanish galleons from the West Indies under their protection; and although the assailed were driven to the necessity of burning their vessels, ten ships of war, together with eleven galleons, richly laden with pieces of eight, were taken, through the skill and activity of the gallant admiral Sir George Rooke.

Marlborough, having received for his services the thanks of parliament, and a grant from the queen of L.5000 per annum, out of the post-office revenue, entered in 1703 on his second campaign, in which the French were rather the gainers. But the next year opened up a scene of the most splendid glory to the confederated arms. It was now the celebrated battle of Blenheim, on the banks of the Danube, was fought. The troops, under Marlborough and prince Eugene, which amounted to about 52,000 men, were opposed by a superior body of 60,000, commanded by the elector of Bavaria, and the marshals Tallard and Marsin. So dreadful was the carnage, that the field and the Danube were covered with the dead; and the engagement so disastrous to the French, reduced their army to about half their number. The allied troops under Marlborough, afterwards re-crossing the Rhine, made themselves masters of Landau, Treves, and Friesbach.

In the same year, 1704, after the prince of Hesse had made an unsuccessful attempt on Barcelona, Sir George Rooke, supported by a considerable force, took from the Spaniards the town and fort of Gibraltar. This place, of such consequence to the English, for the refitting of their vessels, and the protection of their trade in the Mediterranean, has continued ever since in their possession. But of so little value was it deemed at the time, that Sir George was left unrewarded for his useful services, and was even displaced from his command.

The duke of Marlborough, again taking the field in 1705, proposed penetrating into France by the way of Lorraine, when, at the request of the United Provinces, he abandoned his project, and joined the Dutch troops against marshal de Villeroi, who had marched with a formidable army to Liege. De Villeroi was defeated with considerable loss; but desirous, perhaps, of retrieving his reputation, he soon after came to an engagement at Ramilies, where, though the French occupied superior ground, the military genius of the invincible Marlborough led him in half an hour to a complete victory. The result was the conquest of Brabant, and of nearly the whole of Spanish Flanders.

While the French had some advantages in Italy, the allied troops had others in Spain. Philip V. grandson of Louis XIV. had ascended the throne of the latter kingdom, notwithstanding the treaty which had been formerly entered into, for conferring the crown on the archduke Charles, son of the emperor of Germany. The English and Dutch maintained the cause of the house of Austria, in opposition to that of the house of Bourbon. An armament, conducted by the earl of Peterborough and Sir Cloudesly Shovel, arrived on the Spanish coast, spreading alarm among the inhabitants; the fortresses of Lorida and Tortosa surrendered; Barcelona was obliged to capitulate; and the provinces of Valencia and Catalonia were reduced. Philip, on the approach of the hostile army, withdrew from the seat of government; and the archduke, whom the Spaniards and Portuguese contemptuously styled, "Charles, by the grace of heretics, catholic king," was proclaimed at Madrid. But the marshal de Berwick, natural son of James II. aided by the patriotic enthusiasm of bishops, priests, monks, peasants, and even women and children, soon recovered the capital, and brought back Philip amidst shouts and demonstrations of joy. In 1707 Berwick and the duke of Orleans reconquered the whole of Spain, with the exception of Catalonia.

In the meantime a negociation began, which terminated in an event of the utmost consequence to the independence, peace, and prosperity of Britain. Since the accession of James I. in 1603, the sceptres of England and Scotland had been swayed by one sovereign; but, though repeated attempts had been made, no coalition of the two legislatures had yet taken place. The accomplishment of this was left to add splendour to the reign of queen Anne. With the concurrence of both parliaments, she named commissioners from each to meet in the Cockpit at Whitehall, for considering and forwarding so desirable an object. The articles, drawn up and signed by these commissioners, were laid before the respective parliaments for their consent; and, after keen debates between the different parties, and after an amicable adjustment of the matters in dispute, a definitive arrangement was adopted, and the articles of the union were finally ratified in January 1707, when the Scottish parliament was for ever dissolved. In these articles it was stipulated, among other subjects of agreement, "That the succession to the united kingdoms should be invested in the house of Hanover; that all the subjects of Great Britain should enjoy a communication of privileges and advantages; that the laws concerning public right, policy, and civil government, should be the same throughout the nation; that the court of Session, and all other courts of judicature in Scotland, should remain as then constituted by the laws of that kingdom; that Scotland should be represented by sixteen peers and forty-five commoners; that all the peers of Scotland should be peers of Great Britain, and rank immediately after the English peers at the time of the union, and before such as should be created after it; and that they should enjoy all the privileges of English peers, except that of sitting and voting in parliament, or sitting upon the trials of peers."

About this time the French king, trusting to the co-operation of those whose minds were inflamed by their failure in opposing the union, threatened Britain with an invasion in favour of the Pretender, or, as he was called, the chevalier St George. The country became generally alarmed; the Whigs, who had begun to decline in power, combined their influence with that of the Tories in support of the common cause; the *habeas corpus* act was suspended; and the chevalier and his adherents were declared traitors and rebels. A French fleet appeared in the Frith of Forth, but being closely pursued by the English, under Sir George Rooke, it returned to Dunkirk, to the great mortification of the Pretender, who, with tears, expressed his anxiety to get on shore.

The duke of Marlborough still pushed the war on the continent, with his usual success; and while, in 1708, he defeated the French near Oudenarde, and took Lisle, the bulwark of the French frontier, major-general Stanhope, with not more than 300 men, re-

Civil history. duced the island of Minorca. Louis, who had lately offered terms of peace which were not accepted, again renewed his proposals to the Dutch, but they refused to listen to them without the concurrence of the allies, who, by making extravagant demands, to which France could not accede, protracted hostilities. Next year the famous battle of Malplaquet was gained by the confederate troops, after much skill and valour had been displayed on both sides. The campaign of 1710 and 1711, opened a free passage almost to Paris, and spread alarm among the inhabitants.

Meanwhile, the Tories, whom the duke of Marlborough had deserted, on finding the Whigs more ready to support his schemes of humbling France, had begun to plot his disgrace. Harley and Bolingbroke supplanted him in the favour of the queen, and employed every method which malice and revenge could suggest to exasperate the nation against him. The whig system, on which the greater part of this reign had been conducted, was completely overturned; Marlborough was dismissed from all his employments, and the command given to the duke of Ormond; and, after many negociations at Utrecht, peace was at length signed at that place by the belligerent powers, on the 31st of March 1713.

The duke of Marlborough retired to the continent, furnishing a striking instance of the evanescence of popularity and the instability of fortune. Although at one time the idol of the queen and the boast of parliament, he was now the object of their hatred and neglect. He was accused of insatiable avarice; his abilities were insulted; and even his courage was called in question. But since the military achievements at Cressy and Agincourt, a braver and more successful general had not appeared. In the course of ten campaigns, he never laid siege to a town, without taking it, nor engaged in a battle without gaining a victory. Nor was he less able in the cabinet than in the field.

On the 1st of August 1714, Anne died of an apoplexy, in the 50th year of her age, and the 13th of her reign; having survived her husband, prince George of Denmark, six years. She was adorned with all the virtues of her sex; and the epithet of the "Good Queen Anne" has been applied to her, expressive of the excellence of her character as a sovereign. With her ended the line of the Stuarts, who had been alike remarkable for their misconduct and their misfortunes, and who had swayed the sceptre of England 111, and that of Scotland 343 years.

George I.—Agreeably to the established order of succession, George, elector of Hanover, maternally descended from Elizabeth, daughter of James I. acceded to the throne. He came to England with strong prepossessions against the Tories, who, professing to believe in a divine hereditary right, favoured the claims of the Pretender; and he soon evinced an inclination to support the Whigs, to whom he was chiefly indebted for the crown. The great duke of Marlborough, returned from a voluntary exile, was again raised to honourable appointments; and in all the offices of trust under government, a total change was effected. In the new parliament, the Whigs, who had become by far the predominant party, treated with much severity the Tory, or Jacobite faction. Disorder and tumult were the consequences, to prevent which the *habeus corpus* act was suspended; and an edict, still in force, was passed, declaring it to be felony, without benefit of clergy, for persons unlawfully assembled to continue an hour together, after the proclamation should be publicly read. Civil history.

In 1715, many disaffected and Jacobite Scots rose in rebellion under the earl of Mar, who proclaimed the chevalier St George, and set up his standard in the Highlands. The rebel army, to the amount of 10,000 men, being furnished with arms, ammunition, and officers from France, made themselves masters of the whole county of Fife, and then marching towards Dumblane, they were met by the duke of Argyle, commander in chief of the forces in North Britain, whose troops were considerably fewer than half the number of the enemy. After a desperate engagement, in which both sides claimed the victory, the earl of Mar was quickly abandoned by the greater part of his irregular followers. The death of Louis XIV. on whose exertions the hopes of the Pretender principally rested, operated, doubtless, as a considerable disappointment, especially since the duke of Orleans, now intrusted with the regency of the kingdom, had entered into a strict alliance with his Britannic majesty. Yet the infatuated Chevalier embarked at Dunkirk, and landed at Peterhead, on the coast of Scotland, with only six gentlemen in his train. Proceeding to Feteresso, he was complimented by the earl of Mar and his other adherents; having received addresses from the clergy and laity of the episcopal communion in Aberdeenshire, he made his public entry into Dundee; and on the 7th of January 1716, he arrived at Scoon, where he assumed all the functions of royalty, and fixed the day of his coronation. His imaginary reign, however, was of short duration; for, pursued by the duke of Argyle, and destitute of every thing necessary for maintaining the war, he, accompanied by Mar, Drummond, and other persons of distinction, sailed back to the continent, in a vessel which lay in the harbour of Montrose.

During these transactions, the rebel arms in the north of England were attended with even less success. The earl of Derwentwater and Mr Foster proclaimed the Pretender at Morpeth and Alnwick, made a fruitless attempt on Newcastle, and, on receiving re-inforcements from the Scottish borders, took Preston without opposition. Here, being assailed by the royal troops under general Wills, they were obliged to surrender on the terms of unconditional submission to the mercy of the king.

The rebellion being thus suppressed, the laws were put in force against the deluded insurgents. Of the ringleaders, who were impeached and condemned to die, none suffered but the earls of Derwentwater and Kenmuir. An act, considered a daring infringement on the ancient constitution of the kingdom, was passed, for trying the private prisoners in London, and not at the place where the offence was committed. While some of them effected their escape, four or five were hanged, drawn, and quartered at Tyburn; twenty were executed at Manchester and Preston; and about one thousand, on petitioning the royal clemency, were transported to North America. On pretence of giving stability to government, a bill, at his time introduced, for extending the continuance of parliament to seven years, was carried in both houses by a great majority. Thus, one innovation followed another, and, although the people might murmur, it was impossible to obtain redress.

Incensed at the king of England for purchasing Bremen and Verden from the Danes, Charles XII. of Sweden threatened Britain with an invasion,—a threatening which would have probably been accomplished had it not been prevented by the fall of his Swedish majesty at the siege of Fredrickshall, in Norway. Meanwhile, with a view to secure his German dominions, George paid a visit to Hanover, and, among the several alliances into which he entered, that termed the *quadruple alliance*, contracted between him, the emperor, the States-general, and the king of France, is the most remarkable. This alliance laid the foundation of a quarrel with Spain. In 1718, Sir George Byng, sent with 22 ships of the line to the Mediterranean, engaged, near Syracuse, in Sicily, the Spanish fleet, consisting of 27 sail, and took the whole squadron, excepting three vessels, which the conduct of their vice-admiral Cammock, a native of Ireland, preserved. War was immediately proclaimed; and the Spaniards, determined to retaliate by supporting the claims of the Pretender, dispatched a powerful armament towards Britain, which was entirely dispersed by a storm off Cape Finisterre. Two frigates, however, conveyed the earls Marischal and Seaforth, and the marquis of Tullibardine, with 300 Spanish soldiers, to Scotland, where they were joined by 1600 Highlanders; but, being attacked by the regular troops under general Wightman, they were soon defeated, leaving to the rebel leaders, as their only resource, an escape to the continent. The failure of this expedition, in conjunction with the bad success of the Spanish arms in other quarters, constrained his catholic majesty to accede to the quadruple alliance.

In 1720, the Irish parliament was deprived of the right of final jurisdiction, and was rendered dependent on that of England; and in the same year the South Sea Company obtained an act to increase their capital, by redeeming the public debts. The greater part of the nation became stock-jobbers, and the stock, which had risen to L.1000 *per cent.* suddenly fell as low as L.150, to the ruin of many families. Vengeance was taken on the directors, who had enriched themselves by their fraudulent transactions; they were removed from their seats in parliament, and declared incapable of holding any office of trust in future; a bill was passed for confiscating their estates, and every thing, within the power of government, was done to alleviate the distress of the sufferers.

The king having received from the duke of Orleans intelligence of a plot, acquainted the new parliament, which met in 1722, with the designs of his enemies in favour of the Pretender. Enraged by this information, the Commons resolved that the sum of L.100,000 should be raised on the real and personal estates of papists, to aid in defraying the expences occasioned by the late disorders, and all the Scots of that communion were ordered, without delay, to register their names and their estates. Of the individuals concerned in this treasonable conspiracy, Christopher Layer, a young templar, was convicted, condemned, and executed; and Francis Atterbury, bishop of Rochester, on the mere evidence of hearsay and conjecture, was sent into perpetual banishment, where he soon after died.

In consequence of an alliance, recently contracted between the courts of Madrid and Vienna, it was contended in parliament, that the object of this coalition was to place the Pretender on the throne of Britain, and to wrest Gibraltar and Port Mahon from the English. These confederated powers denied, indeed, that any such object existed; but it was nevertheless deemed expedient to put the naval and military force of the kingdom on a respectable footing, and to enter into a counter-convention with France, Sweden, Denmark, and Prussia. To intercept the Spanish galleons from America, a squadron under admiral Hosier was dispatched to the West Indies, without success. The Spaniards, who in return invested Gibraltar, were equally unfortunate; after lying before it for some months, they were obliged to raise the siege, with the loss of 10,000 men. Preparations were every where making for war, when the mediation of the French king put a temporary stop to the farther effusion of blood.

On the third of June 1727, George having appointed an administration in his absence, set out for his electoral dominions, and in four days arrived at the town of Voet in Holland. He reached Delden on the ninth; and next morning, while prosecuting his journey, a stroke of the palsy rendered it necessary to carry him to Osnaburgh, where he expired on the 11th, in the 68th year of his age, and the 13th of his reign. In his person he was about the middle size; in his features he was regular and manly; and in his deportment he was grave and majestic. He was an able general, a consummate politician, and a mild and engaging prince; and if he ever departed from the principles of the British constitution, the fault was ascribable not to himself, but to the suggestions of a venal ministry, to whom the interior government of the kingdom was almost entirely committed.

During the interval between the death of Charles II. and of George I., Britain rose to high eminence in every department of literature and science. Among the divines may be mentioned Tillotson, Patrick, Cumberland, Clarke, Pearson, Beveridge, and Bentley. Among the philosophers, Newton, Boyle, Halley, Flamstead, Keil, Hay, Locke, Cudworth, and Berkley. Among the physicians, Friend, Mead, Sydenham, and Pitcairne. Among the political writers, Davenant, Swift, Addison, Bolingbroke, and Trenchard. And among the poets, Congreve, Prior, Rowe, Pope, Parnel, and Gay.

George II.—As soon as an express arrived with the news of the king's death, his son, George II. ascended the throne. He adopted the political system established by his father, continued Sir Robert Walpole at the head of the treasury, and avowed his intention to preserve the constitution in church and state. On his accession, the two parties, which divided the kingdom, were denominated the *court* and *country* factions. His first speech to parliament announced his sincere resolution to merit the love of

Civil history. his people; and numbers who were dissatisfied under the former reign, expressed their attachment to his person and government. The civil list was fixed at L.800,000; and the disputes about the increase of the national debt, which now amounted to L.52,000,000, terminated in favour of the ministry.

The congress which opened at Soissons in 1728, proved ineffectual for allaying the contentions of Europe, and the Spaniards committed, with impunity, depredations on the commerce of Britain. Petitions from the merchants of London, Liverpool, and Bristol, complaining of these depredations, were presented to parliament, and the Commons, in addresses to the king, prayed him to use every effort to check such daring aggressions. A peace was soon after concluded with Spain, by the treaty of Seville. In 1733, Sir Robert Walpole proposed levying a partial excise on tobacco; a proposal, which, from the dread of such an impost extending to other articles, was violently resisted by the country party. The ferment it produced throughout the nation constrained the minister to drop his scheme, even with a majority of 61 of the Commons in its favour. Emboldened with this success, the opposition members endeavoured to obtain a repeal of septennial parliaments; but, mortified at losing their object, they left the house, and retired to their seats in the country.

Although, by the treaty of Seville, all differences between Spain and Britain seemed to be adjusted, the Spaniards sought occasion for a rupture, by distressing the commerce of the British, and disputing their right to cut log-wood in the bay of Campeachy. Their vessels were boarded and plundered by the captains of the *guarda costas*, one of whom cut off the ear of a captain Jenkins, and desired him to carry it to the king, with the assurance that the Spaniards would serve him in a similar manner, should an opportunity occur. It is not to be wondered at that these insulting and predaceous practices were complained of, and that the voice of the nation was loud for war. Between the two crowns, however, a convention was concluded, in which it was stipulated that Spain should, by certain payments, indemnify the subjects of Britain for the injuries they had sustained. The terms of this convention were soon violated, and hostilities commenced in 1739.

To prosecute a war so congenial to the wishes of the people, supplies were readily granted; and admiral Vernon, being dispatched with only six ships to the coast of South America, destroyed the fortifications of Porto Bello, almost without opposition, and almost without loss. About this time, commodore Anson was sent to annoy the Spaniards in the South sea. But detained beyond the proper season, through the mismanagement of the ministry, his vessels were dispersed by a storm. Having touched at the island of Juan Fernandez, where he was joined by one ship and a frigate, he sailed along the coast of Chili, and plundered and burned the town of Paita. In traversing the great Pacific ocean, he refreshed his men at the island of Tinian; and his hopes were at length gratified by the capture of a Spanish galleon from the Philippine islands, a prize valued at no less than L.313,000. Another armament with which Anson was destined occasionally to co-operate across the isthmus of Darien, made an unsuccessful attempt on Carthagena. Civil history.

The failure of this enterprize, together with other unfortunate naval operations, incensed the nation against Sir Robert Walpole. By the new elections in 1741, the country party gained the ascendency in the house of Commons, and Walpole, seeing his influence at an end, resigned all his employments. The succeeding administration, by following the steps of their predecessors, became equally unpopular; and a continental war was now determined on to retrieve the honours which Britain had lost.

On the death of the emperor of Germany, his daughter, the queen of Hungary, was, in terms of the *Pragmatic treaty*, heir to his dominions. But France, regardless of this treaty, set up the duke of Bavaria as her rival; and while Prussia deprived her of Silesia, the rest of her territories were attacked by France, Saxony, and Bavaria. In this extremity, Britain, from generous motives, or it may be with the view of balancing the different interests of the empire, stepped forward to the assistance of the young queen. A body of British troops, strengthened by 16,000 Hanoverians, drove the French from Bohemia; while her own general, prince Charles of Lorraine, stripped the duke of Bavaria of all his hereditary possessions. The British and Hanoverians, trying to form a junction with the prince, gave rise to the battle of Dettingen, which was glorious to the confederated arms.

To make the English relax in their exertions on the continent, the French threatened Britain with an invasion in favour of the Pretender. An armament of 20 ships of the line, and 15,000 troops, was preparing for embarkation at Dunkirk, when Sir John Norris, with a superior fleet, prevented the execution of the design. Between the two kingdoms war was now openly declared. In the Netherlands, the campaign of 1744 was adverse to the allies, who, with a force of about 70,000 men, including British, Dutch, Hanoverians, and Austrians, engaged at Fontenoy a French army amounting to 120,000. The former was defeated, but the losses on both sides, though immense, were nearly equal. To atone for this disaster, the honour of the British flag was retrieved by admirals Rowley and Warren; and the important fortress of Louisburgh in North America, was taken by general Pepperel.

Charles Edward, son of the Pretender, was resolved to make an effort to gain the British throne; and being furnished by France with about L.4,000, seven officers, and arms for 2,100 men, he landed with a frigate on the coast of Lochaber in Scotland, in 1745, accompanied by the marquis of Tullibardine, Sir John Macdonald, Sir Thomas Sheridan, and other adventurers. Marching southward with 1500 Highlanders, he caused his father to be proclaimed at Perth; and his force still increasing as he advanced, he entered Edinburgh without opposition, where the rite of proclamation was again performed. In the meantime Sir John Cope, appointed by government to check his progress, arrived at Dunbar, with his army, from Aberdeen; Charles drew out his troops to meet him; and in an engagement on Tranent-moor, near Prestonpans, the impetuosity of the rebels, in a few minutes, led them to a complete victory.

After remaining some time at Edinburgh, in the empty enjoyment of the title and honours of royalty, the young Pretender, joined by the earl of Kilmarnock, the lords Elcho, Balmerino, Ogilvy, and Pitsligo, and the eldest son of lord Lovat, invaded England, where the duke of Cumberland and general Wade were preparing to oppose him. Having taken the town and castle of Carlisle, he passed through Penrith, Lancaster, Preston, and Manchester, to Derby, little more than 100 miles from London; and then, finding himself disappointed in his expected succours from France, he effected a safe retreat into Scotland, though closely pursued by the king's troops. He proceeded to Glasgow, and from thence to Stirling; and receiving some additions to the number of his followers, he invested the castle. General Hawley left Edinburgh with a considerable force to raise the siege; and the two armies came to a battle at Falkirk; the rebels drove the enemy before them with precipitation, and enriched themselves with the tents and artillery whch fell into their hands.

But the triumphs of Charles were at an end. The duke of Cumberland, with 14,000 men, took the field; the insurgents retired before him towards Aberdeen; and the disastrous action at Culloden, in 1746, decided the fate of the adventurer. Scenes of awful severity followed; the conquerors consigned the whole country around to slaughter, plunder, and desolation. The young Pretender was now reduced to the most distressing situation. A reward of L.30,000 was offered for his head; and to elude the vigilance of his enemies, he sought shelter in the dreary solitude of caves, mountains, and forests. One day, fatigued with wandering, and pressed with hunger, he ventured into the house of a person attached to the opposite cause: "The son of your king," said he, on entering, "comes to beg a bit of bread, and clothes. I know your present attachment to my adversaries, but I believe you have sufficient honour not to abuse my confidence, or to take the advantage of my misfortunes. Take these rags, that have for some time been my only covering, and keep them. You may, probably, restore them to me one day, when seated on the throne of the kings of Great Britain." He succeeded according to his wishes; and after lurking about six months amidst the wilds of Glengary, and trusting his life to the fidelity of fifty individuals, he, at last, with Cameron of Lochiel and other fugitives, embarked in a privateer of St Malo, and escaped to France.

Meanwhile those insurgents, who had fallen into the hands of the victors, were doomed to the most dreadful vengeance. Seventeen officers were hanged, drawn, and quartered, on Kennington-common near London; six were executed at Brompton; eleven at York; seven at Penrith, and nine at Carlisle. The earl of Kilmarnock, and the lords Balmerino and Lovat, were beheaded on Towerhill; and many of the common men were transported to America.

On the suppression of the rebellion, plans were adopted by government for the civilization and improvement of the Highlands. In 1747, heritable jurisdictions were abolished, and the power of the chieftains over their enthralled vassals dissolved. The inhabitants were compelled, under severe penalties, to lay aside their ancient garb for that of their lowland neighbours; but this act was afterwards mitigated by the wise administration of the immortal Chatham. Savage ferocity began to give way to the arts of peace; barren heaths and uncultivated deserts to become fruitful fields; and every thing in those mountainous and neglected regions, to assume a new aspect.

The flame of war still raged on the continent. At Roucroux and La Feldt the allies were defeated; the strongest fortification of Dutch Brabant, Bergen-op-zoom, was taken; and an unsuccessful attempt was made by the English on Port L'Orient. But these advantages on the part of France were counterbalanced by her losses in other quarters. Her army met with reverses in Italy; and her naval and commercial enterprizes were rendered abortive by the active energies of the admirals Anson, Warren, and Hawke. The French king was now desirous of peace; and a treaty, the basis of which was a general restitution of conquests, was, in 1748, concluded at Aix-la-Chapelle, where the earl of Sandwich and Sir Thomas Robinson acted as the plenipotentiaries of Britain.

The only remarkable events which took place during the following short interval of peace were, the colonization of Nova Scotia; the death of the amiable and beloved Frederick, prince of Wales; the alteration of the style, according to the Gregorian calender, by merging the eleven days, between the 3d and 14th of September 1752; and the establishment of the Society for the Encouragement of Arts, Manufactures, and Commerce.

In the treaty of Aix-la-Chapelle, the respective boundaries of the French and British in North America had not been accurately defined; and the disputes arising upon this subject, together with the encroachments of the former power, led in 1755 to an open declaration of war. Admiral Boscawen was dispatched with a squadron to the banks of Newfoundland, where he captured two French ships of war; and orders being issued for seizing, and bringing into British ports, all French vessels, whether outward or homeward bound, a considerable number of them, together with about 30,000 sailors, were soon in the possession of the English. General Braddock, sent out to Virginia to command the forces destined to act against the French on the Ohio, was defeated and slain in the midst of a pathless swamp, not far from Fort du Quesne. But an advantage was afterwards gained over them and the Indians by general Johnson on the lake Ontario; and colonel Monckton drove the enemy from their encroachments on the province of Nova Scotia.

The French, after threatening an invasion of Britain, which never took place, landed in 1756 an army of 11,000 men in Minorca, and invested Fort St Philip. Admiral Byng was ordered out with a squadron of ten ships of the line to raise the siege; but by a partial, if not cowardly engagement with the French fleet under admiral Gallissoniere, he suffered them to escape, and general Blakeney, the governor, was reduced to the necessity of surrendering the place. The voice of the nation was loud against the conduct of Byng, who was, in consequence, brought to public justice, and sentenced to be shot. But the loss of Fort St Philip was more than compensated by the successes of our privateers in Europe and America, and by the splendid achievements of colonel Clive in the East Indies,—achievements which have contributed to the extent and the riches of our Asiatic possessions.

Mr Pitt, being about this time introduced into the administration, adopted a new system of operations against France. An expedition was fitted out for carrying the arms of Britain into that country; it sailed on the 8th of September 1757, and returned without even attempting the object for which it was planned, farther than the reduction of the small island of Aix. Yet, though general Mordaunt, who had the command of the land forces, was acquitted on trial, such was the confidence of the people in the minister, that no murmurings whatever were expressed. The French now attacked the electorate of Hanover, and compelled the duke of Cumberland, at the head of 50,000 confederates, to sign a disgraceful capitulation at Closter Seven; but in the following year, his Britannic majesty having entered into a treaty of mutual defence with the king of Prussia, the Hanoverians, under the Prussian general, prince Ferdinand of Brunswick, drove the enemy from their dominions. On the death of the duke of Marlborough, who had been sent over with 12,000 men to co-operate with prince Ferdinand, the command of the British troops devolved on Lord George Sackville; and, had it not been for a misunderstanding between these two generals, the battle of Minden, so glorious in the annals of military history, would have been more decisive.

The British were equally fortunate in other parts of the globe. In North America, Louisburg, which had been restored to the French by the treaty of Aix-la-Chapelle, was reduced in 1758 by general Amherst; and if general Abercromby failed in his attempt on Crown Point, brigadier-general Forbes succeeded on Fort du Quesne. Admiral Pocock, on the coast of Asiatic India, defeated the French fleet near Fort St George, and a second time near Pondicherry; and the colonels Laurence and Draper obliged the enemy to retire with precipitation from the siege of Madras. In 1759 the African island Goree was taken by commodore Keppel; Guadaloupe surrendered to admiral More and general Hopson; and Quebec, after an obstinate action, in which the gallant Wolfe fell, submitted to general Townsend. In short, the British completed the conquest of the whole of the French empire in North America.

France having again threatened an invasion of Britain, desisted from the attempt, on the defeat of their fleets by Admirals Hawke and Boscawen. The war in Germany continued still undecisive; and the French king, wearied with fruitless operations, made proposals of peace. In the meantime George II. died suddenly at Kensington in the 77th year of his age and the 33d of his reign. His character possessed many excellent qualities; he was humane in his disposition, steady in his attachments, liberal in his religious principles, and equitable in his government. Yet his predilection for his native country was rather conspicuous. Under his reign commerce flourished, and the arts and the sciences made considerable progress.

George III. A. D. 1760.—No prince ascended the throne of England under more favourable circumstances than those which signalized the accession of this sovereign. The propriety of his behaviour, his moderation in avoiding public affairs where his interference could not prove salutary, and the ease and agreeableness of his manners, bespoke general regard. An able and active ministry carried on war with success, and enjoyed popularity at home. The prejudicial affection for the Stuart family, which had so long and so frequently divided or distracted the kingdom, had either entirely ceased to exist, or merely lingered in some romantic minds, as a tribute of compassionate feeling to the remembrance of fallen greatness; and the commercial prosperity of the country, promoted and secured by a multiplicity of manufactures, and a vastly extended navigation, more than kept pace with the large expenditure which her foreign relations demanded. The patriotic and sensible speech which his majesty addressed to parliament, sanctioned and enhanced the pleasing prospect naturally rising from such considerations, and at once, in the most ardent terms, identified the predilections, the sentiments, and the wishes of the monarch, with the happiness and interests of his subjects. Yet, in the judgment of the discerning few who had access to explore the secret springs which were either to realise or to thwart the hopes of the nation, there was not wanting a very sufficient reason for distrust and apprehension, in the influence of the Earl of Bute over his august pupil. Their fears were not long without the confirmation of facts; but even in the partial and tardy manner by which a change in administration was effected, insidious and timid as it might be deemed, there appeared some not unamiable anxiety to reconcile, as much as possible, certain royal prepossessions with the opinions and attachments of the people. Magnanimity of character, indeed, would have gloried in an opportunity of sacrificing personalities at the shrine of public good; but self-denial is too rare among princes to justify discontent when it is not remarkably displayed. The patriotic Mr Legge, who had been unfortunate enough, though with honour, to give offence to the king, when prince of Wales, was dismissed from the office of chancellor of the Exchequer the very day on which parliament was dissolved, and Sir Francis Dashwood, a zealous *Tory*, chosen in his place. At the same time, Lord Holdernesse made a *politic* and *premeditated* resignation of the seals, which were instantly given to the Earl of Bute, who appointed Mr Charles Jenkinson, afterwards Lord Liverpool, his under secretary.

Mr Pitt resigns.—Notwithstanding this change, which plainly indicated the feelings of the monarch, Mr Pitt for a time retained the management of foreign affairs, and prosecuted the war with no inconsiderable success. But he was by no means so buoyed up by any advantages on the part of the allies, or the surrender of Belleisle, and some fortunate operations in the East and West Indies, as to disregard a negociation for peace formerly proposed by France, and now resumed. Sundry advances were favourably received, and a termination of hostilities seemed their natural issue, when the invidious interference of Spain, now intent on the family compact, induced him somewhat indignantly to abandon the conference, and to urge immediate war against that kingdom. But in this advice, to which he was prompted by intelligence of an alliance between the courts of Madrid and Paris, in his imagination highly inimical to Great Britain, he was supported only by earl Temple, his brother-in-law, at that time lord Privy-seal. On this proof of his diminished influence in the cabinet, he thought proper to resign, that, to use his own words, he might not "remain responsible for measures which he was no longer allowed to guide." Such conduct appeared to partake more of obstinacy than true wisdom to the reflecting part of the nation, who could not but approve a wish to avoid a new war in the burdened state of the finances, and who could not perceive that a friendly alliance between those two powers should necessarily contain any articles prejudicial to the welfare of the kingdom. But the public voice, which he had so long and so justly merited, declared in favour of Mr Pitt's determination, whilst the ministry, to which the earl of Egremont acceded in his place, by an equivocal and irresolute behaviour, lost an opportunity of vindicating the correctness of their own views, and, in reality, gave occasion for a semblance of truth to his prophetic anticipations. After some foolish manifestations of pride and false honour, in a negociation between the British and Spanish governments, the two countries found themselves committed in a war, in opposition, apparently, both to their wishes and their interests. The ex-minister, of course, obtained credit for almost more than human sagacity; and the subsequent success of the contest was with equal justice ascribed to the remains of his vigorous spirit, which still shed its influence on the public counsels. His Majesty, on the 8th September 1761, married the Princess Charlotte Sophia of Mecklenburgh Strelitz. Their coronation was celebrated on the 22d of the same month.

Lord Bute retires.—The war with Spain in conjunction with France, which was declared on the 4th January 1762, continued till the 10th February in the following year, when a definitive treaty was concluded at Paris. The terms, which were communicated to parliament in its previous meeting, were not such as the country, proud of its conquests, and vaunting its superiority, expected, and drew forth the indignation and violent censure of Mr Pitt, as "obscuring all the glories of the war, surrendering the dearest interests of the nation, and sacrificing public faith, by an abandonment of its allies." But such sentiments, blazoned as they were by the vehement eloquence of that distinguished character, and eagerly adopted by a people always intent on brilliant warfare, cannot be applauded by the impartial historian, who, at the distance of half a century, can calmly contemplate the real merits of the whole transaction. He will, in fact, have little difficulty in yielding this peace his almost unqualified approbation, and the preference to any practical prosecution of hostilities. But neither the sanction of parliament, nor the benefits likely to accrue from the termination of a war, which had, at all events, required no ordinary pecuniary sacrifices, could screen the new minister, commonly denominated the *Favourite*, now possessed of a power and influence which no individual had enjoyed since the days of Lord Clarendon, from popular dislike, and the effective and widespread energies of the opposition, at present composed of some of the ablest and most distinguished persons in the country, and openly countenanced by the duke of Cumberland, uncle to the king. Lord Bute, whose courage was not equal to his ambition or his pride, beheld the difficulties thickening around him with no small solicitude, and at last, apparently making a merit of necessity, resolved on retiring "to the blessings of the life he loved," rather than await the issue of an embittered and dangerous contention. This very unexpected resignation gave comparatively little satisfaction, because it was imagined a mere artifice to avoid responsibility, whilst his real agency was prolonged in a manner more repugnant to the constitution and well-being of the kingdom.

John Wilkes and the North Briton.—Mr George Grenville succeeded the earl of Bute as First Commissioner of the Treasury; on the death of Lord Egremont the seals were given to the earl of Sandwich; and the duke of Bedford, on his return from Paris, where he had negociated the treaty, was appointed President of the Council in the room of earl Granville, a nobleman who, for many years, and to the close of his life, had occupied that office with the highest respectability. A general coalition of parties was attempted at this period, but without effect, owing, in great degree, to the pertinacity or political honesty of Mr Pitt, who insisted on terms which the king conceived derogatory to royal dignity. The new ministry, therefore, ventured on their own strength to encounter their opponents; and party-spirit raged with more keenness than ever. Among the publications which embodied the virulence and zeal of the popular combatants, a work, edited by the famous John Wilkes, member of parliament for Aylesbury, under the name of The North Briton, gave most annoyance, by its indecent personalities and coarse invectives. Its periodical abuse was tolerated till the appearance of the 45th number, which seemed a studied experiment how far the liberty or rather licentiousness of the press could be carried with impunity to the author. A general warrant was issued for his apprehension. He was lodged in the Tower; his papers were seized, and all access to him was strictly forbidden. In a few days he was brought up to Westminster-hall on a writ of *habeas corpus*, and released by lord chief-justice Pratt, afterwards lord Camden, in consideration of his parliamentary privilege, which, in the opinion of that able and constitutional judge, could only be forfeited by treason, felony, or breach of the peace, whereas Mr Wilkes stood chargeable merely with writing a libel. A prosecution was immediately commenced against him by the attorney-general, to which he refused to answer. In consequence, a message from the king, communicating the whole transaction, was made to parliament, which, after a hot debate, by a large majority, declared the paper in question to be "a false, scandalous, and seditious libel," and ordered it to be burnt by the common hangman. Thus, injudiciously, was an immense degree of importance and eclat given to a production, which, by its own merits, would speedily and irremediably have sunk into oblivion. But the notoriety of its author did not rest here. A variety of proceedings established him more and more as the idol of the people; and it must be confessed, that, notwithstanding his numerous, gross, and unpardonable vices, his heroism and enterprise accomplished essential service to the political liberty of his country.

Project for taxing America.—The minister, on the termination of this at first trivial, but, in its bearings and consequences, momentous affair, hazarded an experiment still more ominous and interesting,—the relief of the financial burdens of the kingdom by a direct tax on its transatlantic provinces. This measure had long before been proposed to Sir Robert Walpole, but rejected by him as highly inexpedient and dangerous. It was reserved for the bustling and narrow-visioned intellect of Mr George Grenville, impressed with a complacent opinion of his all-sufficient dexterity, to venture on a project at once flattering to the pride, and, to appearance, friendly to the necessities of Britain, but which issued in the complete and final loss of her most valuable appendage. There was, however, some display of moderation in his manner of putting it into execution. His resolution to impose certain *stamp-duties* on the American colonies and plantations, for the purpose of levying a revenue payable into the British exchequer, was introduced into parliament in March 1764, but the practical conclusion from it was not decreed till the following year. It gave rise to an animated debate, but was carried through the house by a triumphant majority, and received the royal assent. In vain had memorials and petitions from the colonies poured in from the time that this famous bill was introduced, conveying opinions and urging suggestions against its principle, its justice, and its generosity,—in vain was it contended, that where representation was not awarded, or was impracticable, there taxations could not be inflicted without a manifestation of tyranny quite alien to the British constitution,—in vain did the manly general Conway, with a firm though solitary voice, protest against the *right* thus assumed by the legislature,—or colonel Barré, one of the most eminent speakers in the house, vindicate the freedom, the gratitude, and the loyalty of the Americans, but at the same time predict the fatal efficiency of their jealous love of liberty, so obnoxiously wounded by this alarming measure. The magic power of numbers on which the minister could securely calculate, presented a salvo for every fear, and an indemnity for every presumption. Thus, then, went out this memorable decree to its unhallowed work, a monument of British folly that might be for ever deplored, if the general welfare of mankind were not to be preferred to merely national dignity, and if the history of its operation did not furnish a salutary warning against implicit reliance on the *expressed wisdom* of parliament.

Marquis of Rockingham's ministry.—The victory thus gained by the minister did not secure his power, which was shortly afterwards broken up in a very unexpected manner. Some alarm having been occasioned by the indisposition of the king, it was judged expedient to make provision for a minority, in the event of any of his children being called to the throne in early life. In the arrangements for a regency to answer this purpose, the name of the Princess Dowager of Wales was omitted on the part of the ministry, but afterwards inserted by the Commons, on the motion of one of Lord Bute's friends. The princess took umbrage at such an injurious exclusion, and the court immediately formed a resolution hostile to the offenders. Overtures were accordingly made to Mr Pitt and Lord Temple, through the duke of Cumberland, but were not satisfactorily terminated. A second application to the same individuals was no less unhappy, owing to the inflexible demand of these patriotic statesmen, that there should be a total change of men and measures, to which the court was as inflexibly disinclined. On these failures, as his Majesty was at all events resolved on getting rid of his present ministers, a negociation was opened with the duke of Newcastle and his friends, and accomplished on more courteous terms. The party which thus came into power was that branch of Whigs, afterwards known by the name of *Rockingham*, from the marquis who was now placed at the head of the treasury. Among his colleagues, were the duke of Grafton, lord Winchelsea, general Conway, and Mr Dowdeswell. The combination was altogether highly respectable, and some of its members were no less eminent for talents than virtue. Yet did they encounter the censure and condemnation of Mr Pitt and Lord Temple, as having, by their accepting office, lost a fit opportunity for putting an end to the secret influence of the favourite, which was held so injurious to the country. Their administration which was of short continuance, effected an important concession to America, and other liberal measures. The repeal of the stamp act, particularly, would have been sufficient to merit encomium, though it somewhat mortified the pride of the nation. But it gave offence in a quarter where resentment was never allowed to remain long inoperative.

Ministry and resignation of Lord Chatham.—Mr Pitt, again applied to, formed a ministry, not altogether new, but to the exclusion of Lord Temple, who separated from him in no small displeasure. Being advanced to the peerage by the title of earl Chatham, he choose the office of lord Privy-seal. The duke of Grafton was appointed first lord of the Treasury. The earl of Shelburne succeeded the duke of Richmond, as one of the secretaries of state, general Conway remaining as he was. The Right Hon. Charles Townshend was made chancellor of the Exchequer, and lord chief-justice Pratt, now Lord Camden, accepted the office of lord Chancellor. Mr Pitt little consulted his reputation by his conduct at this period, and in reality lost the confidence and esteem of the people. Nor did the conduct of this ministry, from which, on Lord North succeeding to Mr Townshend, he found it necessary to withdraw, do justice to his principles, and sagacity as its former. It renewed the plan of taxing the colonies, though in a way, as was foolishly imagined, not likely to incur the same objection. In the midst of the discontents and murmurings which it occasioned in the new world, a war broke out in India with Hyder Ally; and the reappearance of Mr Wilkes on the political stage, besides giving rise to some popular disturbances, involved the parliament and the electors of Middlesex in an awkward contest about his eligibility for the honours of a representative.

Lord North's administration.—Lord Camden having sided with Lord Chatham's opposition in the discussion of Mr Wilkes's case, was deprived of the great seal, which fell into the hands of Mr Justice Bathurst, but not till Mr Yorke, who had pledged himself to listen to no offers of the court, put a period to his existence in a fit of remorse at having accepted it. Sundry resignations now took place, and latterly that of the duke of Grafton, who was succeeded by Lord North. Thus at last was organized an administration, which, for twelve successive years, in spite of an enlightened opposition, and the plainest dictates of experience, pursued a ruinous policy, and accumulated misfortunes, disappointments, and a host of taxes on the kingdom.

Extraordinary exertions of Lord Chatham.—The energies of Lord Chatham, for a while depressed by ill health, and a variety of vexations public and personal, unexpectedly broke forth again in 1770, the year in which this ministry was established. Several opportunities were presented for their display. The house of Lords having resolved itself into a committee on the state of the nation, Lord Rockingham moved, in allusion to the case of Mr Wilkes "That the house of Commons, in the exercise of its judicial authority in matters of election, is bound to judge according to the law of the land, and the known and established law and custom of parliament, which is part thereof." This proposition, which is similar to one moved in the lower house by Mr Dowdeswell, but got rid of by the dexterity of the minister, was intended to form part of certain resolutions, implying the condemnation, and leading to the reversal of a vote in the previous session. It was supported with his wonted ability by Lord Chatham, who stigmatized the conduct of the house of Commons in the harshest terms, and denominated its vote in favour of colonel Luttrell, as representative for Middlesex, though he had not a fourth part of the voices of the electors, "a gross invasion of the rights of election, a dangerous violation of the English constitution, and a corrupt sacrifice of their own honour." In order to gratify *individual resentment*, said he, "the laws had been despised, trampled upon, destroyed;—those laws which had been made by the stern virtue of their ancestors, the *iron barons* of old,—to whose virtue and whose blood,—to whose spirit in the hour of contest, and to whose fortitude in the triumph of victory, the *silken barons* of this day owe their honours and their security." This motion having been lost, and a very different one proposed, implying, that any resolution of the Peers, impeaching the judgment of the other house, was a violation of the rights of the Commons, his lordship rose again, and endeavoured to prove the necessity of interference in certain cases, of which the present was one. He conjured the Peers, by the noble blood which flowed in their veins for so many ages, and by the glorious struggles of their ancestors in the cause of freedom, not to behold such an alarming transaction with indifference. "But if," said he, "my lords, the constitution must be wounded, let it not receive its mortal stab at this dark and midnight hour, when almost every eye is closed in sleep, and when robbers and assassins only are awake, and prowling for their prey." The question, however, was decided in the affirmative.

Lord Mayor replies to the King.—Nor were his subsequent exertions in the same cause at all more successful, except in so far as they restored to him a portion, at least, of his former consequence in popular esteem. A candid inquirer into the particulars of this famous controversy, which in reality engaged for some time almost all the attention of the nation, can no more approve of the whole of his lordship's opinions and reasonings, than he can be satisfied with either the ministerial conduct or the popular enthusiasm on this subject. No very inadequate idea of the spirit which existed at this period will be conveyed, by stating a novel and highly hazardous circumstance in the presentation of one of the city's addresses to the king. His majesty had declared, that the contents of a former address and *remonstrance* from the city were "disrespectful to himself, injurious to parliament, and irreconcileable to the principles of the constitution." The city, in a new address, lamented the heavy displeasure which they had incurred, but nevertheless adhered to their former sentiments, and prayed for a dissolution of the parliament. To this his majesty answered, "that he should have been wanting to the public, as well as to himself, had he not expressed his dissatisfaction at their late address; and that he should ill deserve to be considered as the father of his people, could he suffer himself to be prevailed upon to make such an use of his prerogative as was inconsistent with the interest, and dangerous to the constitution of the kingdom." The lord mayor, Beckford, who presented the address, on this reply, demanded leave to answer the king, which, in the state of confusion produced by so unusual a request, was granted. He delivered himself in a spirited manner, and concluded his extemporary speech in the following terms: "Permit me, Sire, farther to observe, that whoever has already dared, or should hereafter endeavour, by false insinuations and suggestions, to alienate your majesty's affections from your loyal subjects in general, and from the city of London in particular, is an enemy to your majesty's person and family, a violator of the public peace, and a betrayer of our happy constitution, as it was established at the glorious and necessary revolution!" The effect of these observations was *obviously* unpleasant; but his majesty very prudently made no reply.

Altercation with Spain.—The public attention at this period was considerably diverted from domestic concerns by an aggression on the part of Spain, which, if the spirit of the people had been alone considered, would have led to a war with that kingdom. But the ministry, not without some appearance of sacrificing national honour, allowed an explanation on the insulting attack which had been made on the Falkland islands, and actually consented, in a secret article, to evacuate them at a certain term; by which means hostilities were prevented. The comparatively trivial value of that possession, could scarcely, indeed, have justified an appeal to the sword; but it is no less certain, that the respective conditions of the two countries would have safely borne out Great Britain in insisting on a more ample concession than was obtained. It was the unfortunate failing of the present ministry, to reserve its spirit and its obstinacy for those who were entitled to the most lenient consideration and indulgence.

Various domestic concerns.—In 1771, some changes of administration took place, in consequence of the death of the earl of Halifax, to whom the earl of Suffolk succeeded as secretary of state for the northern department. The duke of Grafton accepted the office of Privy-seal. This year was distinguished by an accession to the liberty of the press, of material importance to the nation,—the privilege, at first assumed, but afterwards virtually sanctioned, of publishing the debates in parliament without disguise or the employment of initials for the names of the speakers. In the following year, a bill for the enlargement of the toleration act intended to favour the dissenters was carried through the Commons, but lost in the house of Lords; as was also another bill for relief to the clergy from subscription to the thirty-nine articles. But, in consequence of the marriage of the dukes of Cumberland and Gloucester to persons beneath their own rank, an act was passed, prohibiting the descendants of George II. within certain limits, from marrying without the royal consent. Early in this year died the princess-dowager of Wales, in the 53d year of her age, whose influence over the mind of the king, and consequently the concerns of the nation, was too great not to warrant the notice of its termination. The state of India received very marked discussion at this period, and a bill for regulating its government, which passed through parliament, obtained the very general approbation of the people, though experience unfortunately did not demonstrate its beneficial efficacy.

Lord Clive accused.—Among the proceedings of a select committee appointed to enquire into the affairs of that country, the conduct of Lord Clive did not escape notice. Their report brought several very serious charges against him, which necessarily demanded investigation. Colonel Barré signalized himself in the debate. Remarking on an explanation of certain transactions of Lord Clive, he ironically observed, "that the fortunes amassed by the Company's servants were, *no doubt*, all honourably acquired. If the property of the natives was taken without their consent, it was *military plunder*; if otherwise, it was *compensation for services*; if by a commercial monopoly, it was *inland trade*." "The nice and ingenious distinctions made by the noble lord, between bribes and presents, exactions and gratuities, reminded him of a certain Spanish governor of Gibraltar, who, amongst other perquisites of office, had been accustomed to receive an annual donation from the Jews. This people having, on one of their anniversaries, brought him only a thousand sequins, were informed that they should not be favoured with an audience, 'as they were sprung from those who crucified Christ.' They went home disconcerted, but after farther consideration, returned with double the sum, on which they were admitted; 'for, said the governor, poor men! they had no hand in the crucifixion!" Lord Clive defended himself with great ability. A clause in a motion conveying censure on him was rejected, though voted for by the minister; and an amendment in his favour was carried by a respectable majority, which terminated the inquiry. But this success did not relieve Lord Clive from public odium. Nor did his subsequent melancholy and wretchedness, terminated as it was by a self-inflicted death, appear to belie the opinion which had been entertained of his character.

Lord Chatham's testimony in behalf of sectaries.—The bill for enlarging the toleration act being again introduced during the parliament of 1773, was lost, as before, in the Upper House. In the debate on the subject, some virulent remarks of the archbishop of York, who denominated the dissenting clergy "men of close ambition," drew forth the indignant and liberal spirit of Chatham. "The dissenting ministers, said he, are represented as men of *close ambition*,—they are so, my lords, and their ambition is to keep close to the college of fishermen, not of cardinals,—and to the doctrine of inspired apostles, not to the decrees of interested and aspiring bishops. *They* contend for a spiritual creed and spiritual worship. *We* have a Calvinistic creed, a popish liturgy, and an Arminian clergy. The reformation has laid open the scriptures to all,—let not the bishops shut them again. Laws in support of ecclesiastical power are pleaded for, which it would shock humanity to execute. It is said that religious sects have done great mischief when they were not kept under restraint; but history affords no proof that sects have ever been mischievous, when they were not oppressed and persecuted by the ruling church." For several succeeding years the administration of Lord North presents few interesting events, with the exception of what concerned the dispute with the American colonies, to which, therefore, it will be proper to direct attention.

Retrospect of American dispute.—The act of 1767, imposing certain port-duties on the colonies, contained a clause, empowering the crown to establish a civil list in every province, which gave no less offence than the taxes themselves. It was followed by the appointment of an American board of commissioners to be fixed at Boston, which no less plainly and obnoxiously indicated the determination to tax America. These measures were met with a state of discontent, bordering on rebellion, and an agreement among the merchants not to import any goods from the mother country, till redress should be given. Hitherto, without much inquiry, a discretionary legislative power had been pretty generally admitted to reside in the British parliament; but in course of time, and more particularly since the discovery of its object, and the manner in which this power was exercised, the colonists began to argue against the right to legislate for them, as well as to tax them without their consent. Henceforward, then, there was a new and a daily strengthening spirit to be encountered, which the ministry and politicians of Britain do not appear to have previously contemplated as a possible existence. A prejudice, amounting to infatuation, had precluded attention to the progress of political knowledge and the gradual acquisition of separate interests. Its influence was manifested in the instructions transmitted by his Majesty's secretary for foreign affairs, to governor Bernard, requiring the house of representatives to rescind a resolution of the assembly of Massachusett's, which had given birth to a circular letter, recommending the different provinces to enter into joint measures for the redress of their common grievances, and commanding the immediate dissolution of the assembly in case of refusal. But the spirit of opposition was no less displayed in the reply made to this extraordinary and arbitrary requisition: "If the votes of the house are to be controuled by the directions of a minister, we have left us but a vain semblance of liberty. We have now only to inform you (the governor), that this house have voted not to rescind." "Let Britain, said a member of the assembly, rescind her measures, or she will lose America for ever." The dissolution was ordered next day. This altercation attended and followed by various resolute demonstrations, happened in 1768,—an early, explicit, and unequivocal enunciation of the proposition which was afterwards discussed with such terrific arguments. In the midst of the proceedings to which it immediately gave rise, a tumult occurred at Boston, very characteristic of the popular feelings on the subject, and rendered more remarkable by the threatening parade of military force, drawn out to overawe the inhabitants. Such was the disturbance, coupled as it was with various symptoms of a refractory disposition, which occasioned the revival of an obsolete statute in the British legislature, for bringing over persons accused of treason committed beyond seas, to be tried in England, and which induced his Majesty to assure his parliament, "that he would not fail, in the mode they had recommended, to give the most effectual orders for bringing the authors of the disorders, &c. to condign punishment." But the communication of this retributive intention did not intimidate the colonists, nor did the dissolution of their respective assemblies by the governors interrupt their associations to obtain redress. Among other causes of complaint, the statute now alluded to was held peculiarly obnoxious, and highly derogatory to the rights of British subjects." That it was unnecessary there could be no doubt, because, by the local laws and constitutions of the colonies, there was ample provision made for the trial and punishment of delinquents; and that it was easily and extensively liable to abuse could be no less obvious. "How truly deplorable," said the representatives of Virginia in their address to the king, "how truly deplorable must be the case of a wretched American, who, having incurred the displeasure of any one in power, is dragged from his native home, conveyed to a distant land, where no friend will alleviate his distresses, and where no witness can be found to testify his innocence!" The irritation extensively propagated throughout America, was little allayed by the concessions of 1769, or rather indeed was augmented; because, in repealing all the taxes, with the exception of that on tea, there seemed to be an artful design to establish a pernicious principle and a precedent, in a manner which should leave only a shadow of reason to the objectors, and therefore excite more odium against them. This finesse, accordingly, utterly failed; and one opinion spread universally, that nothing short of a total repeal of all the revenue acts, and the injurious statutes of the present reign, could secure the union of Great Britain and her colonies. A sullenness and discontent, which were chiefly manifested on various occasions in the assembly of Massachusetts, continued till 1773, and too certainly, like the deep-seated annunciations of an earthquake. portended some explosion. The acquisition of some confidential letters, written by the governor and his friends, which fell into the hands of Dr Franklin, agent of the representatives in England, and which he transmitted to his constituents, proved the existence of a design to pursue *coercive measures* against the colonists, and of course gave a stimulus to their resentment. Their petition for the removal of the governor was ignominiously rejected; and Dr Franklin, who presented it, received the grossest abuse from Mr Wedderburne, afterwards lord Loughborough, at that time counsel for the defendants. In the same year the duty on tea was removed, at the urgent solicitation of the East India company, who felt severely the want of the American market, and who offered, in compensation, to pay double the sum on the export of that article. But they were egregiously disappointed in the result of this appeal. The colonists at once perceived that the principle of taxation was still kept up, though they were not in the first instance subjected to its operation. They unanimously resolved, therefore, that it should not take effect; and in reality so far succeeded, that in no place was the delivery of the tea allowed to be made. A more violent proceeding occurred at Boston, where the mob boarded the vessels in which it had been conveyed, and threw it into the sea.

Views of opposition as to America.—Such extraordinary obstinacy was no way softened down in the message of the king to the parliament of 1774, or in the concurrent representation of the minister, the effect of which was to produce the very general opinion that vigorous measures were absolutely necessary. The opposition made but feeble resistance to the proposal for retaliation or chastisement, but objected strongly to some of the modes by which it was to be carried into execution. "By this bill," said Colonel Barré, alluding to an act similar to one formerly mentioned, providing for the transmission of a certain class of offenders to Great Britain, "by this bill you are offering the last of human outrages to the people in America, by subjecting them, in effect, to military execution: instead of sending them the olive-branch, you have sent the naked sword. What madness is it that prompts you to attempt obtaining that by force, which may be with so much more facility and certainty procured by requisition?

Civil history.

Retract your odious exertions of authority, and remember that the first step towards making them contribute to your wants, is to reconcile them to your government." A speech of Lord Chatham, on occasion of a bill subsequently introduced, contained the essence of his sentiments on this momentous dispute. "I condemn in the severest manner the turbulent and unwarrantable conduct of the Americans in some instances, particularly in the late riots at Boston; but, my lords, the mode which has been pursued to bring them back to a sense of their duty, is so diametrically opposite to every principle of sound policy, as to excite my utmost astonishment. You have involved the guilty and the innocent in one common punishment, and avenge the crime of a few lawless depredators upon the whole body of the inhabitants. My lords, the different provinces of America, in the excess of their gratitude for the repeal of the stamp act, seemed to vie with each other in expressions of loyalty and duty; but the moment they perceived that your intention to tax them was renewed, under a pretence of serving the East India company, their resentment got the ascendant of their moderation, and hurried them into actions which their cooler reason would abhor. But, my lords, from the whole complexion of the late proceedings, I cannot but incline to think, that administration has purposely irritated them into these violent acts, in order to gratify their own malice and revenge. What else could induce them to dress taxation, the father of American sedition, in the robes of an East India director, but to break in upon that mutual peace and harmony which then so happily subsisted between the colonies and the mother-country? My lords, it has always been my fixed and unalterable opinion, and I will carry it with me to the grave, that this country had no right under heaven to tax America. It is contrary to all the principles of justice and civil policy: it is contrary to that essential, unalterable right in nature, ingrafted into the British constitution as a fundamental law, that what a man has honestly acquired is absolutely his own, which he may freely give, but which cannot be taken from him without his consent. Pass then, my lords, instead of these harsh and severe edicts, an amnesty over their errors; by measures of lenity and affection allure them to their duty; act the part of a generous and forgiving parent. A period may arrive when this parent may stand in need of every assistance she can receive from a grateful and affectionate offspring."

First Congress's proceedings.—The effect of the recent measures of the British legislature, when communicated to America, was precisely what the observations and reasonings thus enforced, pointed out as likely to be realized. One undivided spirit of indignation and resentment sprung up among the colonists with electric celerity and force. A general congress of deputies from all the states, in spite of a proclamation by general Gage, declaring such a combination unlawful, hostile, and traitorous, was held at Philadelphia, on the 4th September 1774. It professed to feel deeply the sufferings of their countrymen in Massachusetts, under the unjust, cruel, and oppressive measures of the British parliament,—approved of the wisdom and fortitude which they had displayed in their resistance,—trusted that the united energies of America would carry conviction to the British people, of the unwise, unjust, and ruinous policy of the present administration,—agreed to support their countrymen in their laudable opposition,—published a declaration of rights for which they determined to contend;—but resolving, in the first instance, to pursue pacific measures, prepared an address to the people of Great Britain, and a loyal and humble petition to his majesty. These two documents are extraordinary productions, and deserve very marked consideration. Towards the close of the former they give a serious warning: "We think ourselves bound in duty to observe to you, that the schemes agitated against these colonies have been so conducted, as to render it prudent that you should extend your views to the most unhappy events, and be in all respects prepared for every contingency." After deprecating, in the latter, his Majesty's displeasure at the *language of freemen*, they say, "Your royal indignation, we hope, will rather fall on those designing and dangerous men, who, daringly interposing themselves between your royal person and your faithful subjects, have at length compelled us, by the force of accumulated injuries, to disturb your majesty's repose by our complaints."—"We ask but for peace, liberty, and safety. We wish not a diminution of the prerogative, nor do we solicit the grant of any new right in our favour. In the magnanimity and justice of your majesty and parliament, we confide for a redress of our grievances, trusting, that when the causes of our apprehensions are removed, our future conduct will prove us not unworthy of the regard we have been accustomed in our happier days to enjoy. And appealing to that Being who searches thoroughly the hearts of his creatures, we solemnly profess that our counsels have been influenced by no other motive than a dread of impending destruction. We implore, therefore, your majesty, as the loving father of all your people, connected by the same bands of law, loyalty, faith, and blood, not to suffer the transcendent relation formed by these ties to be farther violated, in uncertain expectation of effects, which, if attained, never can compensate for the calamities through which they must be gained." The resolutions of this first congress were universally confirmed by the provincial assemblies; and thus, the rudiments of an independent state may be said to have been completely organized.

Americans slighted by the ministry.—But the eloquence, the complaints, and all the other demonstrations of united feeling on the part of the Americans, were utterly lost on the infatuated ministry, or rather aggravated and fostered their proud purpose, to enforce obedience, and never to relent in the demands of British supremacy. Nay, they were even guilty of the superlative inconsistency, or most culpable affectation, of practically disparaging the resources and the courage of the colonists, whilst the whole of their proceedings, and the unvaried tenor of their language, were calculated to put every possible desire, and every potential means of resistance into full requisition. Thus they reduced a fifth part of the number of seamen voted last year, and the first lord of the

Admiralty had the folly to assert, that the Americans "were neither disciplined nor capable of discipline; and that, formed of such materials, and so indisposed to encounter danger, their numbers would only add to the facility of their defeat." Lord Chatham again endeavoured, though in a very infirm state of health, to arrest the impending calamity. He reprobated more pointedly than ever the conduct of administration, and advised, as essential to the slightest hope of reconciliation, the removal of the British army from the scene of contest: "America," said his lordship, "cannot be reconciled,—she ought not to be reconciled to this country, till the troops of Britain are withdrawn from the continent; they are a bar to all confidence,—they are a source of perpetual irritation,—they threaten a fatal catastrophe. How can America trust you, with the bayonet at her breast? How can she suppose that you mean less than bondage and death?—The recal of your army I urge as necessarily preparatory to the restoration of your peace. By this it will appear, that you are disposed to treat amicably and equitably, and to consider, revise, and repeal, if it should be found necessary, as I affirm it will, those violent acts and declarations which have disseminated confusion throughout the empire. Resistance to these acts was necessary, and therefore just; and your vain declarations of the omnipotence of parliament, and your imperious doctrines of the necessity of submission, will be found equally impotent to convince or enslave America, who feels that tyranny is equally intolerable, whether it be exercised by an individual part of the legislature, or by the collective bodies which compose it. The means of enforcing this thraldom are found to be as ridiculous and weak in practice, as they are unjust in principle." His lordship's bill for settling the troubles in America was rejected by a majority of 61 to 32 voices, on a motion of Lord Gower, president of the council, that it should not be suffered to lie on the table. His lordship, highly resenting this indignity, entered on his own vindication, and inveighed against his opponents in the most cutting manner. "By the indecent attempt now made to stifle this bill *in embryo*, ministers might hope that the contents of it would sink into silence and oblivion. But, though rejected here, it would, he trusted, ever remain a monument of his earnest, however ineffectual, endeavours to serve his country. It would, at least, manifest how zealous he had been to avert the impending storm, which seemed ready to burst over us, and overwhelm the empire in ruin. He acknowledged himself, however, on cool reflection, not indeed much surprised, that men who hate liberty should also hate those that prize it; that those who want virtue themselves, should persecute them who possess it. Since the first entrance of the present ministers into office, the whole of their political conduct had been one continued series of weakness, temerity, ignorance, despotism and corruption. In one view only did they appear sound statesmen and able politicians,—in a strict and unwearied attention to their own interests. Such were their characters, and such their abilities, that no plan of government could be expected to succeed in their hands; and they themselves, he doubted not, were fully conscious that the adoption of any system of conciliation, founded on a wise and rational policy, would annihilate their power, and reduce them to that state of insignificance for which God and nature had designed them."

Americans declared in rebellion.—On the following day, Lord North, in the house of Commons, moved an address to the king, declaring America in a state of rebellion, and assuring his majesty, "that it is their fixed resolution, at the hazard of their lives and fortunes, to support his majesty against all rebellious attempts, in the maintenance of his just rights, and those of the two houses of parliament." This gave rise to a vehement debate, and in some degree startled the more moderate adherents of the ministry. An amendment, proposed by Mr Charles Fox, who had a little before been rather rudely dismissed from the treasury bench for his refractoriness, "deploring that the information which the papers laid before them had afforded, served only to convince the house that the measures taken by his majesty's servants tended rather to widen than to heal the unhappy differences between Great Britain and America, and praying an alteration in the same," was rejected by a majority of 304 to 105 voices. A conciliatory proposition, afterwards very unexpectedly advanced by Lord North, alarmed the high prerogative party, but was in reality quite nugatory, as it implied the right of taxation, to which, it was well known, the Americans were insuperably opposed. Mr Burke, who may be considered as the representative of the Rockingham party, also proposed a series of conciliatory resolutions, of a much more judicious and effectual nature,—but they were negatived in a very triumphant manner; and every other attempt to accomplish the same desirable object proved equally unsuccessful. The session closed without a single act which could conduce to the restoration of tranquillity in the now universally disaffected provinces, but to the perfect satisfaction of his majesty, who declared from the throne "his entire conviction that the most salutary effects must result from such measures, formed and conducted on such principles." Never was opinion more erroneously formed, or hope more egregiously disappointed.

Progress of hostilities.—In a smart but desultory engagement at Lexington, where the first blood was shed, the loss of the British was nearly 300 men, whilst that of the colonists did not exceed 90,—a very ominous commencement of this most impolitic war. The congress unanimously rejected Lord North's conciliatory plan, as had been anticipated, and paid no attention to a conditional offer of an amnesty on the part of general Gage. They chose Mr Hancock president of their assembly, and gave the command of their army to George Washington. An attack on the American entrenchments at Bunker's-hill, to the north of Boston, under general Howe, succeeded in its object, but cost the British upwards of 1000 men, including more than 80 officers,—a loss, it was remarked, nearly equal to that at the battle of Minden, where the British infantry had to sustain the fire of the whole French army. Though encouraged by their success in this early stage of the contest, the congress again petitioned the king for peace, but were informed, through their agent, Mr Penn, that

Civil history.

no answer would be given! The Canadians, applied to by the British, declined taking part in the quarrel. They were afterwards invaded by the colonists under general Montgomery, but without success. In 1776, the duke of Grafton, who had seceded from the ministry, made another conciliatory motion, which was as ineffectual as any that had preceded it. Treaties were now entered into with some of the German princes for the hire of troops to serve against the colonists,—a measure severely, but vainly, reproached by the opposition. But even this compact was commendable in comparison of the employment, in the same cause, of the savage tribes inhabiting the frontiers and neighbourhood of the revolted provinces. This year was remarkable for various military operations, in which, though often and signally unfortunate, the Americans acquired military habits and skill, and saw good reason for the confidence which they had placed in their own fortitude, and the varied abilities of their general. But the chief event was the unanimous declaration of independence on the part of the delegates from the thirteen colonies, solemnly promulgated on the 4th July. This important act was most indignantly stigmatized in his majesty's speech, as presumption, rebellion, treason,—words which were very differently construed by the parties now at issue. On the rejection of a motion by lord John Cavendish, those members of opposition attached to the Rockingham principles, absented themselves from parliament, on the allegation, that all discussion of ministerial measures was utterly useless.

Progress of hostilities in 1777.—The probability or certainty that the French would avail themselves of the contest between Great Britain and the colonies, besides his former opinions, which every day's experience confirmed, determined Lord Chatham once more to labour at the work of reconciliation. His speech, on moving an address to his majesty to take the most speedy and effectual measures for putting a stop to the present unnatural war, contained some remarkable passages. "We have tried, said he, for unconditional submission,—let us now try what can be gained by unconditional redress. The door of mercy has been hitherto shut against them; you have ransacked every corner of Germany for boors and ruffians to invade and ravage their country;—for to conquer it, my lords, is impossible,—you cannot do it. I may as well pretend to drive them before me with *this crutch!*" "America, my lords, is now contending with Great Britain under a masked battery of France, which will open as she perceives this country to be sufficiently weakened by the contest, and finds herself sufficiently prepared. France will not lose so fair an opportunity of separating, for ever, America from this kingdom. This is the critical moment,—for such a treaty must and will take place should pacification be delayed: and war between England and France is not the less probable because professions of amity continue to be made." "If it be asked, why should we submit to concede? I will tell you, my lords. Because you have been the aggressors from the beginning; you ought, therefore, to make the first overture. I say again, my lords, you have been the aggressors. You have made descents upon their coasts, you have burnt their towns, plundered their country, made war upon their inhabitants, confiscated their property, proscribed and imprisoned their persons; you have injured, oppressed, and endeavoured to enslave them. America is therefore entitled to redress." The motion was lost by a large majority: and the session closed in June with a speech from his majesty, filled with exuberant compliments to parliament on the evidences which they had afforded of their discernment of the true interests of their country! In the early part of the campaign, Washington prudently avoided a general battle. He hazarded one at the passage of the river Brandywine, where his loss amounted to about 1300 men, after which he retired towards Philadelphia, but could not hinder general Howe entering that city in triumph. He ventured another engagement at Germantown, but was obliged to retreat. In the whole of these operations, it was more and more evident, that the Americans were improving in the military character, and hence the probability of overcoming them progressively diminished. Their success was vastly greater in the north, where general Burgoyne, who had just arrived from England to supersede general Carleton, after obtaining sundry advantages, found himself at last necessitated to capitulate to the American army under general Gates. The tidings of this most disastrous event, when communicated to parliament early in December, produced very general surprise and mortification. Lord North, affected to tears, acknowledged he had been unfortunate, but vindicated his intentions. The opposition, of course, were not wanting in censure and sarcasm; and, from this period, fairly enough calculated on a diminution of ministerial strength. Lord Chatham signalized himself in a manner worthy of the reputation which his political sagacity, however disregarded, and his manly eloquence, however inoperative, had acquired.

France joins America; death of Chatham.—The despondency of the ministers was somewhat relieved during the recess of parliament, by the exertions and encouragement of individuals for prosecuting the war. But it was evident at their next meeting that a modification of public opinion had taken place. Thus a motion by Mr Fox for abandoning the plan of conquest, was supported by the largest minority that had yet opposed the measures of administration; and Mr Burke's motion against the employment of Indians in the contest, though negatived, had 137 votes in its favour. Lord North, accordingly brought forward a plan for conciliating the colonists, which in reality was in substance what had before been recommended by the duke of Grafton. But a concession, such as it offered, was now too late; and it seemed the height of absurdity to imagine that America, having declared, and with hope contended for independence, would abandon it on the extorted confessions and virtual acknowledgment of inability to accomplish its object on the part of the British legislature. His lordship's propositions met with a very indifferent reception from some of his former supporters of the high prerogative party, as degrading to the country, and a pusillanimous concession to armed rebels; and the opposition, again, though they generally approved of them, were no ways sanguine as to their probable effect, and did not lose the opportunity which they afforded of conveying censure on the former system. The reflections of Mr Fox on the defence of the minister, were peculiarly galling, and had too much foundation in truth. "His lordship had attempted a justification of the most unjustifiable measures which had ever disgraced any government, or ruined any country. But his arguments might be collected into one point, his excuses were comprised in one apology,—in a single word,—ignorance; a palpable and total ignorance of every part of the subject. He had hoped, and was disappointed; expected a great deal, and found little to answer his expectations; he thought the Americans would have submitted to his laws, and they had resisted them; he thought again they would have submitted to his armies, and they had defeated them; he then made conciliatory propositions, and thought he would succeed, but they were rejected; he appointed commissioners to make peace, and he thought they had powers, but he found they could not make peace, and that they had not sufficient powers. The present concessions, had they been offered in time, would undoubtedly have been successful; for, however obscure his former propositions of conciliation might be deemed, necessity had at length compelled the noble lord to speak plain. But what censure would be found sufficient for those ministers who had adjourned parliament in order to make a proposition of conciliation, and then neglected to do it until *France had concluded a treaty with the united and independent States of America, and acknowledged them as such!*" The treaty thus first adverted to, was in a few days afterwards acknowledged by the ministry, and gave rise to an address to the throne, expressing the highest indignation at that kingdom, and assuring his majesty of the most zealous support of parliament. In the debate which occurred on moving an amendment to this address in the house of Lords, a very serious difference of opinion between certain members of opposition was brought to light, the existence of which, it is indubitable, materially tended to prolong the contest with the colonies. The Rockingham party, as might have been anticipated from their uniform principles, unreservedly admitted the independence of America, and asserted the total impossibility of recovering what had been wantonly thrown away. Not so the phalanx of which Lord Chatham was the chief, who had always, very unfortunately for his country, viewed that party with a jealous and averting eye, and whose last exertions, in deciding against this concession, shed a semblance of inconsistency on his political life. But there was a spirit of heroism in his indignant resistance to the final loss of so valuable an acquisition, which must ever rank with the most memorable events of the times. "My lords," said he, "I rejoice that the grave has not closed upon me, that I am still alive to lift up my voice against the dismemberment of this ancient and noble monarchy. Pressed down as I am by the load of infirmity, I am little able to assist my country in this most perilous conjuncture: but, my lords, while I have sense and memory, I never will consent to tarnish the lustre of this nation by an ignominious surrender of its rights and fairest possessions. Shall a people, so lately the terror of the world, now fall prostrate before the house of Bourbon? It is impossible! I am not, I confess, well informed of the resources of this kingdom; but I trust it has still sufficient to maintain its just rights, though I know them not. Any state, my Lords, is better than despair. Let us, at least, make one effort;—and if we must fall, let us fall like men." The duke of Richmond, whose motion had thus been opposed, having made a reply expressing his total ignorance of the means by which the combination of America with France could be successfully encountered, and calling on his lordship to point them out, if they were in existence, Lord Chatham rose again with eagerness, as if impatient to deliver some important idea; but before he had uttered a word, he fell down in a convulsion. The house immediately cleared; and the patriot, a little recovered, was conveyed to his villa in Kent, where, after languishing for several weeks, he died in the 70th year of his age.

Lord North's conciliatory plan fails.—The commissioners appointed, under Lord North's bill, to treat with the colonists, executed their mission so far effectually, that they left the Americans in a far worse state of irritation than they had found them; and thus the plan of conciliation was again defeated. Hostilities were carried on, in the meanwhile, in a most malignant manner, without any particular decision; but the accession of France to the the cause of America, gave no small addition of burden to the already distressed finances of Britain. The ministry still resolved on the vigorous prosecution of the war, and had the countenance of great majorities in voting a corresponding address to the speech from the throne, which opened the winter session. Yet was there something alarming to them in the unusually respectable numbers which supported the views of opposition on certain important occasions. A motion by the marquis of Rockingham, conveying censure on the American commissioners for a manifesto, in which they menaced the colonists with a *material change* in the subsequent conduct of the war, should they persevere in their obstinacy, was remarkable for the striking manner in which he addressed himself to the bench of bishops, but experienced a rejection, like every proposed measure from the same quarter. A protest, signed by thirty-one peers, among whom there was only one spiritual lord, Dr Shipley, bishop of St Asaph, testified at the same time the humanity and the failure of the noble mover.

Shipley's plan for dissenters.—The prelate now named, deserves more particular and highly commendatory notice, for an excellent and liberal speech in this parliament, in behalf of the protestant dissenters. He expressed his most cordial acquiescence in the repeal of those penal laws which had long been the disgrace of the national church; but he objected to the condition annexed to it, viz. the imposition of a confession of faith, however short, and general, and true,—such as he hoped he should have the virtue, if called upon, to seal with his blood. He absolutely disclaimed for himself any authority, civil or sacred, to impose this creed upon other men. By such imposition the present bill, which professes to repeal all former penal laws, is converted into a penal law itself; for those who do not subscribe the declarations still remain liable to them. The truth contained in the declaration, 'that the Scriptures are the revealed will of God, and the rule of faith and practice,' was, indeed, acknowledged by every protestant." "But supposing the existence of any set of Christians who should reject our canon of Scripture, who should build their faith on the basis of tradition, or on the supposed illumination of the Spirit, would you, my lords," said he, "persecute them for believing Christianity upon arguments that suit their own understandings? Such men would undoubtedly be in error; but *error in religion is the very ground and subject of toleration*."—"It is the duty of magistrates, it is, indeed, the very end of magistracy, to protect all men in the enjoyment of their natural rights, of which the free exercise of their religion is one of the first and best. All history is full of the mischiefs occasioned by the want of toleration; but no one has ever yet pretended to shew, that any public evils have been occasioned by toleration."—"The ruling party is always very liberal in bestowing the title of schismatic and heretic on those who differ from them in religion, and in representing them as dangerous to the state. But the contrary is the truth. Those who are uppermost, and have the power, are the men who do the mischief, while the schismatics only suffer and complain." "I am not afraid of those tender and scrupulous consciences who are over-cautious of professing or believing too much; if they are sincerely in the wrong, I forgive their errors, and respect their integrity. The men I am afraid of, are the men who believe every thing, and subscribe every thing, and who vote for every thing."

National difficulties increase.—Before the prorogation of parliament in 1779, a message from his majesty communicated the fact of an addition being made to the enemies of Britain, in a manifesto by the court of Spain. This event had been predicted by the opposition, but thought quite improbable on the part of the ministry. Its disclosure, therefore, afforded ample mortification and invective to the political combatants. The nation, however, was not yet sufficiently humbled to concede the independence of America, the condition on which Spain, certainly with some appearance of generosity, offered its mediation between the two countries. One highly important consequence of the alliance thus formed against Britain, was the necessity which Ireland felt for arming in its own defence,—a measure constituting an era in the history of that kingdom. The parliament, which met in November of this year, witnessed the renewed exertions of the opposition; but the motions for censure were still strongly negatived. In a debate on one of these, Lord Gower, in no small degree, sanctioned certain opinions which had long been entertained by the antagonists of the administration. "He had presided, he said, some years at the council-table, where he had seen such things pass, that no man of honour or conscience could any longer sit there! The times were such as called upon every man to speak out; sincerity and activity in councils could alone restore energy and effect to the government." By this time the delusion which had abused the public mind began to lose its efficacy, and the people, smarting under the accumulating evils of an unhappy war, became somewhat clamourous for economy, and a change of measures.

Success and failure of opposition.—This revulsion of sentiment was conspicuous on several occasions. A great number of the counties held meetings for the purpose of petitioning parliament for redress of grievances. York led the way, represented by Sir George Saville. The ruinous consequences of the war, the profuse expenditure, the undue influence of the crown, and the urgent necessity of correcting abuses, were stated in the strongest language. The petition was signed by more than eight thousand freeholders;—"it was first moved, said the baronet, in a meeting of six hundred gentlemen; and there was, he believed, more property in the hall where it was agreed to, than was contained within the walls of the house of Commons. It was a petition, therefore, to which the administration would not dare to refuse a hearing, however the arts of ministerial finesse might be employed to defeat its purpose." After a number of such petitions had been presented, Mr Burke brought forward his celebrated plan of reform, in one of the most brilliant speeches ever addressed to a popular assembly. It consisted of five separate bills, and was in part sustained, notwithstanding all the efforts of the ministry. But a signal victory was gained by the opposition on the 6th April, in the case of Mr Dunning's famous motion, "that the influence of the crown had increased, was increasing, and ought to be diminished." The minister on this occasion drew out all his forces, and was particularly supported by the lord advocate of Scotland, Henry Dundas, afterwards Lord Melville, who, by way of defeating the motion, proposed as an amendment, to prefix the words, "that it is now necessary to declare,"—an addition of so trivial a nature as to give no offence to the opposition. In the division on this amended resolution, there were 233 ayes, and only 215 noes, leaving a majority of eighteen against the court. This triumph was followed up by three motions, naturally rising out of the original proposition, which were all carried in defiance of the wishes, the entreaties, the deprecations, and protests of Lord North. He recovered a majority, not indeed the most encouraging, on another motion, by Mr Dunning, to address the king not to dissolve the parliament, or prorogue the session, till measures should be taken to diminish the influence of the crown, and correct the evils complained of. The opposition, so far successful, was imagined to have been not a little shorn of its strength during the adjournment occasioned by the speaker's illness. Some encouragement had no doubt been given to weak consciences by the minister, who again saw his ranks filled in a respectable manner, and thus, therefore, was blasted the hope which such a multiplicity of petitions, so respectfully recommended, and such strenuous endeavours, so prosperously commenced, had excited throughout the kingdom.

Lord George Gordon's riots.—The capital, in the month of June 1780, exhibited a frightful scene of confusion, riot, and outrage, the contemplation of which for a time absorbed every thought, and filled

Civil history.

the mind with the serious apprehension that the bonds of social life were utterly dissolving. History must stigmatize the event as an enormous disgrace to any civilized country, and brand the agents as the odious abettors of an ignorant and brutal fanaticism. It is humiliating to be obliged to add, that the infuriated malignity which incurs such censure had its chief stimulus, if not its origin, from a part of the empire justly entitled to the distinction of superior education and liberality of sentiment. In the session of 1778, an act had been passed, relieving the Roman catholics from several heavy penalties which characterized the bigotry of a former century. This humane interposition of the legislature was generally commended in England, but received a very malign construction in the northern kingdom, in the capital of which some very indecorous proceedings, tolerated, if not actually sanctioned by the magistracy, resulted in a society denominated the "Protestant Association," intended to adopt measures for effectually opposing any concessions to papists. Of this disgusting fraternity Lord George Gordon was chosen president, a man of high connections, and some good parts, but whose judgment was totally bewildered in worthless conceits, and a still more worthless enthusiasm. The leaven of the association gradually extended to the sister kingdom, where, at last, it surmounted the bounds of common sense, as well as common humanity, and bade defiance to the legal authorities of the country. A petition for a repeal of the obnoxious law being prepared, was undertaken to be presented to parliament by the insane leader, as a member of the house of Commons, only on the express condition that he should be attended by no fewer than 20,000 men. But this requisition was vastly exceeded by the zeal or curiosity of the populace, who convened in St George's Fields on the 2d June of the present year. Their demeanour was at first peaceable enough, but as their fervour augmented, they became more and more unruly, and at last testified a total disregard to liberty of conscience and freedom of opinion. Their leader, during the debate on the petition, frequently addressed them without, in a manner calculated to inflame their minds, and not without success. On the adjournment of the house, the mob commenced their destructive operations, by demolishing some Roman catholic chapels. The following day was quietly got over, but on the next, which was Sunday, several such outrages were committed in the neighbourhood of Moorfields. Still more extensive was the devastation of Monday; and on Tuesday, which was the day appointed for considering the petition, the injurious intentions of the mob became more conspicuously alarming, by an attack on Newgate and Clerkenwell prisons, from which they liberated their comrades, and the destruction of Lord Mansfield's house in Bloomsbury Square. The succeeding day beheld the King's Bench, the Fleet prison, the New Compter, and a vast number of private dwellings, on fire; attempts were also made on the bank and post-office, but happily did not succeed. It was not till the evening of Thursday, nor without much bloodshed, that tranquillity was restored. Lord George Gordon being taken into custody, was tried for high treason, but acquitted, whereas a great number of the rioters, brought before the tribunal of Lord Loughborough, suffered the full rigour of the law. The general effect of this infamous disturbance was serviceable to administration, by producing the greatest dread of popular interference, however laudable or necessary the object might be. County associations, accordingly, got into disrepute, and were deserted by those who had formerly given them the highest encouragement.

War with Holland; Armed Neutrality.—The contest with America was carried on in the southern states with unrelenting energy. Charlestown had fallen into the hands of sir Henry Clinton; colonel Tarleton defeated the provincials at Waxsaw; and Lord Cornwallis was signally successful in South Carolina. But the operations in the north were less important. One of the most interesting events was the defection of general Arnold from the cause of his country, and his engaging in the royal service. The intercourse between him and sir Henry Clinton, which led to this desertion, proved fatal to the amiable and accomplished major André, who was seized as a spy, and executed in an ignominious manner, notwithstanding the urgent solicitations of the British general, and his own earnest request to have the death of a soldier. The joy of the ministry at Lord Cornwallis's success was very great, and gave rise to extravagant anticipations. To this cause may probably enough be ascribed the haughty manner in which the States-General were used at this period, and which ultimately brought on a war with them, not, however, without a degree of popular applause very unsuitable to the real distresses and embarrassments of the country. Thus Britain was engaged with no less than four enemies, without the aid of a single ally. But Holland was not the only power which complained of the violated rights of neutrality. The empress of Russia taking the lead in asserting the freedom of navigation, obtained the concurrence of the other northern states, in establishing the famous confederacy, known under the name of the "Armed Neutrality," which seemed to give satisfaction to every kingdom of Europe, with the exception of Britain, the power, in reality, against whose pretensions it was specially directed. One of the heaviest misfortunes experienced this year, was the capture by the Spaniards of the East and West India fleets in the bay of Biscay, a loss unparalleled in the commercial history of the country, since that of the Smyrna fleet in the time of king William.

Parliamentary proceedings 1781.—The events of the following year were very diversified, and materially affected the condition of the kingdom. It is proper to commence with the parliamentary proceedings. A communication as to the rupture with Holland, gave rise to a warm debate, in which Mr Burke and Mr Thomas Townshend distinguished themselves on the opposition principles, in the house of Commons, and the duke of Richmond and lord Camden among the Peers. But the responding addresses were nevertheless carried by great majorities. Mr Burke again brought forward his reform-bill, which was rejected by a majority of 233 to 190 voices. The debate, to which it now gave rise, was memorable for a speech in its support by Mr William Pitt, then a ve-

Civil history.

ty young man, but already in possession of those great talents which he had afterwards such opportunities for displaying. The minister found himself still more warmly attacked on bringing forward the public account. His lordship's mode of negociating a loan for 12 millions afforded particular facility for the severest censure, which was dealt out to him unsparingly by Mr Fox: "In order to carry on a wicked, impolitic, and bloody war," said that intrepid orator, "the minister would not scruple to extort the last guinea from the pockets of the people. The noble lord stands convicted of having made, in the character of agent and trustee for the nation, an improvident, scandalous, and profligate bargain, for which he deserves public execration and exemplary punishment." But the minister still proved victorious, although it was perfectly obvious that gross abuses prevailed in the matter at issue. This was recorded by a protest of several peers in the upper-house, "in testimony of their strongest condemnation of the terms of the loan, and of the motives which they conceived dictated terms so very disadvantageous to the crown and the nation." And further, a motion afterwards made by Sir George Saville, for a select committee to inquire into its circumstances, was rejected by a majority of 46 only, in a house of near 400 members. A ministry of less impudence, or more feeling, would have construed such an expression into any thing rather than an approval of their conduct. But they required still stronger condemnatory indications to force them to a relinquishment of their offices. Near the end of the session, Mr Fox's motion for resolving the house into a committee to consider the cause of the American war, was ably supported by Mr Pitt, whose vehement language on this occasion might seem to have afforded an example and a precedent for the future invectives of his illustrious opponent: "It was a war," he said, "conceived in injustice, matured in folly, and whose footsteps were marked with slaughter and devastation. It exhibited the height of moral depravity and human turpitude. The nation was drained of its best blood, and its vital resources, for which nothing was received in return but a series of inefficient victories or disgraceful defeats,—victories obtained over men struggling in the holy cause of liberty,—or defeats which filled the land with mourning for the loss of dear and valuable relatives, slain in a detested and impious quarrel." This motion, too, was lost. Much of the present session was occupied in discussing the affairs of India; and particularly in reforming the judicial proceedings of the supreme civil court, against which complaints and petitions had been transmitted to parliament. A bill for new-modelling the supreme court of judicature at Calcutta, and for directing its future proceedings, passed into a law. After much discussion, a temporary bill was also passed, for continuing to the East India company the benefit of their exclusive trade and territorial possessions for a limited term, and for this boon they were at the same time charged with the sum of L.402,000.

India.—The military operations in India this year assumed a very formidable aspect. The success which had attended Hyder Ally, enabled him to augment his forces; but he was vigorously opposed by the British troops, when general Coote took the chief command in the Carnatic, and in three actions completely routed the enemy. In consequence of disputes arising between the rajah of Benares and the British government in India, a new rajah was appointed, and a larger tribute was obtained by the company. When the intelligence of the Dutch war reached India, in August, the settlements in the island of Sumatra, belonging to the states of Holland, were attacked, and fell an easy prey to British authority. The port and fortress of Negapatam, in the Tanjore country, was a more difficult enterprise, but at last shared the same fate.

Civil history.

America.—The embarrassed state of the American finances, the consequent privations to which their army was subjected, and the murmuring and discontent which had long prevailed in it, and at last broke out into open mutiny, gave some hope that their less vigorous resistance would be followed with better success to the British arms. Lord Cornwallis having made preparations for active warfare, entered into North Carolina, was opposed in that quarter by general Greene, and, after various movements, defeated the army of the latter; but not being in a condition to pursue his advantages, he found it necessary to withdraw his exhausted troops to the vicinity of Wilmington. Finding his situation at this place insecure, the British commander formed the resolution of marching to Virginia to effect a junction with the army in that quarter; and in the course of a month from the end of April, he reached Petersburgh. In August he took post with 7000 troops at York town, which stands on a peninsular spot between the rivers York and James, and proceeded to strengthen it with the necessary fortifications. This place was selected as a permanent station, from which enterprizes might be carried on both by sea and land. Before this time general Arnold, with a body of troops, had conducted a kind of marauding expedition along the shores of Virginia and the banks of its rivers, and, driving the different parties of the militia of the country before him, had destroyed ships, naval stores, and merchandise to a great amount. But, in the meantime, Washington gave out that it was his intention, in conjunction with the French, to attack New-York, while his real purpose, in the movements which he began to make, was the relief of Virginia. To continue the deception, the combined French and American troops approached very near to New-York; but suddenly crossing the north river, and marching through the Jerseys to Philadelphia, they proceeded afterwards, partly by land, and partly by sea, to Baltimore, and finally arrived at Annapolis in Maryland.

The British and French fleets, the former consisting of 19, the latter of 24 ships of the line, had a partial engagement off the mouth of the Chesapeak; and the French having been reinforced by a squadron off Rhode-island, remained masters of the river, while the British ships retired to New-York. To prevent Lord Cornwallis from retreating to Carolina, Count de Grasse, the French admiral, blocked up York-river, and with his armed vessels occupied a considerable extent of James-river. The British commander was now completely invested in Yorktown, by an army of about 16,000 French and American troops, and 5000 militia, and had no other defence than earthen works hastily thrown up. On the 6th October, the trenches were opened against him, with nearly 100 pieces of heavy cannon. But after a spirited resistance, and a successful sortie from the British lines, he was compelled, on the 19th, to surrender, when between 5000 and 6000 men, many of whom were sick or wounded, and 1500 sailors, became prisoners of war.

Naval enterprises.—A fleet of 27 sail of the line, under the command of admiral Darby, sailed on the 13th March for the relief of Gibraltar, the garrison of which, from the close blockade, was now subject to great privations from the want of provisions. He effected his purpose without being disturbed by the Spanish fleet, which, to the amount of 30 sail of the line, was then cruizing near Cadiz. A small squadron, under the command of commodore Johnstone, sailed from England at the same time, with 3000 land-forces, for the purpose of reducing the Cape of Good Hope. During the voyage, a smart engagement took place with a French squadron under admiral Suffrein, who arrived first at the Cape, and landed some French troops. Commodore Johnstone, thus anticipated, deemed any attempt on Cape-town impracticable, and confined his operations to an attack on some Dutch East Indiamen in Saldanha bay. The crews of the Dutch ships run their vessels on shore and set fire to them; but by the active exertions of the British seamen, four large ships were rescued from the flames, and the commodore, with his own ship and the frigates, conveyed his prizes to England, while general Meadows, commanding the land forces, proceeded with the rest of the fleet to India.

West Indies.—The West Indies was the scene of some important transactions this year. An expedition under admiral Rodney and general Vaughan, for the recovery of St Vincent, was relinquished without hazarding an attack; but the Dutch island of St. Eustatius surrendered to the same force, without any resistance on the part of the governor, who had not heard of the commencement of hostilities between the two countries. As this island had been for some time a free port and general emporium for West Indian and American produce, immense booty was obtained; and, besides merchandise to the amount of more than 3 millions Sterling, above 250 vessels, with rich cargoes on board, fell into the hands of the captors; while a fleet of thirty West Indiamen, which had shortly before sailed for Holland, was taken by two men of war, and a frigate sent after them. The inhabitants of this ill-fated island were treated with great rigour; indiscriminate confiscations of private property took place, and several of the Jews were condemned to banishment, and transported to St. Christophers. The island was recovered by a small force, under the marquis de Bouille in November, and a good deal of spoil still remained to enrich the victors.

Engagement with the Dutch fleet.—A large convoy protected by a force of eight ships of the line, ten frigates, and five sloops, sailed from the Texel in July, and having fallen in with the British fleet, of nearly equal force, under the command of admiral Hyde Parker, on the Dogger-bank, on the 5th August, a dreadful conflict commenced, and continued for nearly four hours; no ship was taken or sunk during the action; but one of the Dutch ships of 68 guns went down in the night, with all her wounded men, before she reached port.

Combined fleet of France and Spain.—The combined French and Spanish fleet, consisting of 49 ships of the line, appeared off the mouth of the English channel; and admiral Darby, with 21 British ships of the line only, from defective intelligence, narrowly escaped this superior force, and, having returned to Torbay, moored his ships across the entrance. Being reinforced with some ships, which gave him the command of a fleet of thirty sail, he was ordered to sea to protect a West India convoy which was then expected; but he was detained by contrary winds in Torbay till the middle of September; and after deliberating on the propriety of attacking him in that position, the French and Spanish commanders returned to their respective ports. The French fleet was refitted at Brest, and sailed in December with 19 ships of the line and a large fleet of transports, for the East and West Indies, under convoy; admiral Kempenfelt, with only 12 sail of the line, a 50 gun ship, and 4 frigates, fell in with the French fleet during a gale of wind, when it was considerably dispersed; and of the convoy, which had fallen astern, he captured 20 ships, laden with warlike stores; but no engagement took place between the hostile fleets.

1782.—The meeting of parliament, after the Christmas recess, was occupied with a motion for an inquiry into the conduct of the first lord of the admiralty; and the subject of the American war being introduced a second time, a resolution was moved, containing a declaration against offensive war with America. The latter motion was carried by a majority, as well as an address to the king, formed upon the resolution. From the change of sentiment in the house of Commons, it was expected that the prime minister would have retired from an office in performing the duties of which he had lost the confidence of parliament. That period at last arrived, when Lord North declared in the house that the administration was dissolved.

New ministry.—In the new ministerial arrangement the marquis of Rockingham was appointed first lord of the Treasury; the earl of Shelburne and Mr Fox secretaries of State; Lord Camden president of the Council; the duke of Grafton lord Privy-seal; Lord John Cavendish chancellor of the Exchequer; admiral Keppel, then created a viscount, first lord of the Admiralty; the duke of Richmond master-general of the Ordnance; the duke of Portland Lord-lieutenant of Ireland, and Lord Thurlow was continued lord Chancellor.

The discontents in Ireland formed the subject of consideration in the house of Commons early in April; and the causes of these complaints being removed by the interference of the British legislature, the Irish parliament voted L.100,000 for raising 20,000 Irish seamen. Various plans for promoting economy and reform were introduced by the new ministry. Mr Pitt's political career commenced with a

Civil history. proposal for a committee to inquire into the state of the representation in parliament. But while the new ministry were still engaged in their plans of improvement, the death of the marquis of Rockingham produced a very material change in their arrangements. He was succeeded by the earl of Shelburne; and, in consequence of great differences having existed in the cabinet between the most distinguished persons in the administration, Mr Pitt was appointed chancellor of the Exchequer. The affairs of India occupied a large share of the attention of parliament during the whole of the session.

West Indies.—The West Indies was the chief scene of the war during this year. In the early part of it, Demerara and Essequibo were retaken by the French and restored to Holland; the marquis de Bouillé with 8000 men took St Christophers, and the islands of Nevis and Montserrat shared the same fate; and great apprehensions were entertained for Jamaica, which it was scarcely expected could resist the immense force which the French and Spaniards then possessed in the West Indies, if once combined and skilfully directed. It was the object of the British admiral to bring the French fleet to an engagement before this junction was effected. On the 8th April, De Grasse sailed from Martinique; and intelligence of this movement having reached Sir George Rodney, the commander of the British fleet, he sailed instantly in pursuit of the enemy; came in sight, off Dominica, the same night; and next day the van of the British engaged with the main body of the French. In this rencounter two of the French ships were disabled, and left the fleet. Some of the English ships also suffered greatly, but kept their station.

Rodney's naval victory.—On the 11th of April the body of the French fleet was nearly out of sight, when two of the ships that had been damaged in the action of the preceding day were observed to fall off from the rest, and would have been cut off, had not De Grasse, with his whole fleet, bore down to save them. By this movement, the British had an opportunity of bringing on a general engagement, which commenced early next morning, and continued till sunset, with the most determined courage on both sides. In this action, Rodney was the first who put in practice the manœuvre of breaking the enemy's line, which, on many occasions since his time, has given such decided advantages to the British navy. The French admiral's ship, the Ville de Paris, of 112 guns, after dreadful carnage, struck her flag to Sir Samuel Hood, in the Barfleur. Four other ships of the line were also taken, and another was sunk in the engagement; and two more ships and two frigates fell into the hands of the victors some days afterwards. Not a ship of the English fleet was lost, and the whole loss of men did not exceed the number killed in the French commander's ship alone. Admiral Rodney, on his arrival at Jamaica, was hailed as the saviour of the island, and on his return to England was rewarded with a peerage.

Other military operations.—The Bahama islands were reduced by a Spanish armament from Cuba; a French squadron was sent out against the settlements of the Hudson's-bay company, which were not prepared for resistance; and the buildings being destroyed, one magazine excepted, which La Perouse, the commander of the expedition, humanely left furnished with provisions for the winter supply of the merchants, who had fled to the woods, the invaders returned without molestation; and the Dutch lost some of their settlements on the coast of Africa. In the bay of Biscay, admiral Barrington took a large French ship, and twelve of her convoy, with troops and stores, for the East Indies; and the combined French and Spanish fleets from Cadiz fell in with the outward bound Newfoundland and Quebec fleets, and captured eighteen ships.

Memorable attack on Gibraltar.—All the resources of power and ingenuity were called into action by the Spaniards, to recover possession of the fortress of Gibraltar; the preparations this year exceeded every former attempt; ten floating batteries, so constructed that they were supposed to be secured against sinking or being set on fire, were furnished with brass cannon of great weight; a fleet of 48 sail was in readiness to co-operate; new batteries were opened on the land side; and the aid of 12,000 French troops gave spirit and vigour to the Spanish army. The battering vessels, moored at the distance of 900 yards from the rock, began the cannonading on the morning of the 13th of September; but the irresistible showers of red-hot shot from the fortress struck terror and dismay among the besiegers; smoke and flames appeared in the ships, which blew up in succession, and next day not a vestige was seen of this formidable armament. The loss of men among the enemy, who were killed or perished in the flames, was very great; while the number killed, and the damage sustained in the garrison, on this memorable day, was comparatively trifling. An attempt made by the enemy to cut off the garrison from the supply of stores and provisions, was fortunately frustrated by the skill and bravery of Lord Howe, who completely succeeded in protecting the convoy to the port of Gibraltar, in the face of a fleet greatly superior.

Naval disasters.—The Royal George, of 108 guns, and one of the finest ships in the British navy, being at anchor at Portsmouth, was heeled to one side to examine the lower works, and in that position being thrown off the balance by a squall while the ports were open, the water rushed in, and she instantly went to the bottom, with admiral Kempenfelt, all her officers, and eight or nine hundred persons on board. A fleet of 100 merchantmen from Jamaica, under convoy of seven ships of war, some of which were French prizes taken by admiral Rodney, were overtaken, on the 16th September, by a dreadful gale on the banks of Newfoundland. Many of the merchant ships perished in the storm; five of the men-of-war never reached land; and of the fate of the Ville de Paris, the boast of France, and the noble trophy of the splendid British victory, a single individual, who was found floating on a piece of the wreck, only survived to communicate the intelligence.

North America.—No active warfare was carried on in America. The hostile armies in New-York and its vicinity were so nearly equal in strength, that they seemed little disposed to come to close quarters. But, on the 30th of November, the provisional articles of peace were signed at Paris, between the commissioner from Britain and those from the United States, in which the independence of the latter was fully recognized; and thus the long-protracted struggle was brought to a termination.

East-Indies.—The military operations in the East Indies were numerous and important. Trincomalee, in Ceylon, was taken by Sir Edward Hughes, in the end of the preceding year; but this valuable settlement and port was recaptured by the French admiral Suffrein in the present. The war with Hyder Ally and his son, Tippoo, was carried on with various success, till the termination of hostilities in June next year, when the intelligence of a general peace reached India.

1783.—The subject of the peace with France, Spain, and America, formed the most important discussion in parliament at its meeting after the recess; and, on a division, the majority was against the ministry. A resignation followed, and the famous *coalition ministry*, one of the most remarkable political events of the times, was formed. It was so denominated from the singular union of persons of opposite parties. The duke of Portland was first lord of the Treasury, Lord North and Mr Fox secretaries of State, and Lord John Cavendish chancellor of the Exchequer. Parliament was much occupied in arranging and settling the affairs of Ireland, some domestic concerns connected with Great Britain, and particularly with the India bill, the object of which was the regulation of the affairs of the East India company. This bill was rejected in the house of Lords, and the same day the two secretaries of State were required to deliver up the seals of their office. The new ministry was formed on the succeeding day, at the head of which was placed Mr Pitt, then only in his 24th year, as first lord of the Treasury and chancellor of the Exchequer.

1784.—When parliament met in January, a singular spectacle was exhibited of a ministry retaining its place while at open variance with the house of Commons; and various motions were presented and carried hostile to administration. Parliament was at last dissolved, and when it met on the 18th May, the state of affairs assumed a very different aspect. The amendment on the address was rejected by a large majority. Among the proceedings of parliament, the commutation act, by which the duty on tea was lowered with the view of preventing smuggling, and the window tax was increased in proportion; and the establishment of the board of controul, the members of which were to be nominated by the king, for the government of the affairs of the East India company, formed the chief features. The financial estimates included a loan of six millions, and some new taxes; and an act was passed for the restoration of the estates in Scotland forfeited by those who were engaged in the rebellion in 1745.

In the end of last year the subject of reform in parliament excited a great ferment in Ireland. At a meeting of delegates from the province of Ulster, held at Dungannon, it was resolved that a convention of representatives from the whole volunteer army should assemble at Dublin. The convention met, and the plan of reformation was produced and considered, and the day following a motion was made in the house of Commons, for leave to bring in a bill for the more equal representation of the people in parliament. This motion, as being supported by the force of arms, was rejected by a great majority. The subject was renewed in parliament early in the present year, and met with a similar fate. The citizens of Dublin, exasperated at this defeat, held an aggregate meeting, and addressed circular letters with a proposal for a national congress to assemble in Dublin, and composed of five persons elected from every county, city, and town. The most vigorous measures were adopted by government to prevent such a meeting from taking place. But the congress assembled on the 25th October, though in an incomplete form; various resolutions were passed, and a strong recommendation was issued for a full and better organized meeting at a future period. The distress of the manufacturers of Dublin was another cause of great discontent and popular commotion; and the motion for imposing protecting duties in favour of Irish manufactures being rejected in the house of Commons, a violent disturbance took place among the populace, and the mob actually broke into the house and reproached the members for their partiality to the interests of England; but they were fortunately repulsed by the guards without bloodshed.

1785.—One of the first subjects which came under the consideration of parliament, was the affair of the Westminster election, in which a scrutiny had been demanded by one of the candidates. A warm discussion followed, in which a good deal of personal altercation took place between some of the principal speakers. The debts of the nabob of Arcot was another topic of parliamentary investigation; but the motion for a more strict scrutiny into the nature of these debts was lost by a considerable majority. Mr Pitt, following up the plans of reform which he had projected before he came into administration, made a motion for leave to bring in a bill to amend the representation of the people in parliament. He proposed to transfer the right of electing representatives from the decayed boroughs, to the counties and principal unrepresented towns; giving to the owners and holders of the disfranchised boroughs a pecuniary compensation, and to extend the right of voting for knights of the shire to copy-holders. This scheme of compensation was not approved, and, after a long and keen debate, the motion was negatived.

Ireland.—The propositions introduced into parliament during this session for adjusting the commercial intercourse between Great Britain and Ireland, occupied a large share of its attention; but the discontents still continued in the sister kingdom. The national congress for parliamentary reform met in January, and held several adjourned meetings; and a bill on the same subject being brought into the house of Commons, was again rejected; the city of Dublin continued through the summer in a state of great perturbation; and the interference of the military was required for the suppression of mobs and riotous proceedings.

1786.—The first important question which was brought into parliament, was a measure proposed by the duke of Richmond of fortifying the dock-yards of Portsmouth and Plymouth, at an expence of L.760,000, the amount of the estimate calculated by a board of engineers. An animated discussion followed, and when the division took place, the numbers on each side being exactly equal, the plan was rejected by the casting vote of the speaker. Mr Pitt's celebrated scheme for the gradual reduction of the national debt, was brought forward in March; and, according to this plan, one million Sterling, was granted annually to commissioners, to be appropriated as a sinking fund, for the purpose alluded to. The policy of the principle now adopted, of making the income of the state so far exceed its expenditure as to leave a surplus for diminishing the national debt, was universally acknowledged, and the motion was carried without a division; but some objections were made to the mode proposed for effecting this purpose.

The affairs of India also occupied a good deal of the attention of parliament; a bill was passed for enlarging the powers of the governor-general; and the celebrated prosecution of Mr Hastings commenced during this session. During this year, a treaty of commerce and navigation, between Britain and France, was signed at Versailles; and among other conditions of the agreement now entered into between the two kingdoms, the right claimed by the crown of France, to the property of foreigners dying in that country, was abrogated with regard to the subjects of Britain.

Attempt on the life of the king.—Among the remarkable domestic incidents of this year, may be noticed an attempt made by a woman on his majesty's life, while she presented a paper as he was alighting from his carriage at the garden gate of St James's. A blow which she made at his breast with a concealed knife, was fortunately eluded, and as she was about to aim a second stroke, her hand was seized by a yeoman of the guard, and the knife taken from her, while the king, with great coolness and humanity, exclaimed, "I am not hurt; take care of the poor woman, do not hurt her." When she was examined before the privy council, she was found to be one Margaret Nicholson, a person in obscure circumstances from the north of England, and labouring under mental derangement, who had entertained some incoherent notions of right to the crown. As the insanity of this woman was quite obvious, she was not considered a fit object of punishment, and was therefore committed to safe custody as a lunatic.

1787.—The discussion of the commercial treaty lately concluded with France, formed one of the chief topics of consideration on the meeting of parliament. Another important subject of deliberation was, a plan proposed by Mr Pitt for the consolidation of the several duties upon articles in the customs and the excise, and to convert them into single duties upon each article. A motion was also made this session for taking into consideration the repeal of the corporation and test acts; but, after a warm debate, it was negatived.

The preliminary steps for the prosecution of Mr Hastings, formed a prominent part of the transactions of parliament; and whatever opinions may be formed of the influence of party or personal feelings in bringing forward the charges against the governor-general, scarcely any subject before agitated in that assembly afforded so brilliant a display of powerful eloquence. The animated, impressive, and impassioned speeches of Burke and Sheridan on this interesting occasion, have been rarely equalled, and never surpassed, either in ancient or modern times.

Parliament was assembled for the winter-session in November; and the interference of government in the affairs of the United Provinces being noticed in the speech from the throne, became the subject of deliberation. A fleet had been ordered to be equipped, and the land forces recruited. Similar hostile preparations were made on the part of France; but the contests in Holland being settled by the interposition of a Prussian army, a convention took place between Britain and France, for the mutual reduction of their armed force.

1788.—The subjects which occupied the attention of parliament on its meeting after the recess were, a naval promotion declared by the board of admiralty, in which more than forty captains had been passed over, and 16 were advanced to a flag; the right vested in the board of controul of sending troops to India; an additional clause to the mutiny-act, for incorporating in the army a corps of military artificers newly raised; and further regulations for settling controverted elections. The abolition of the African slave-trade was first introduced into parliament this year; and some excellent regulations were adopted for limiting the number of slaves to the tonnage of the vessel in which they are conveyed, and other arrangements connected with their health and comfort. The sum of L.1,340,000 was voted to the American loyalists, in compensation for their sufferings during the war.

Treaties.—A treaty of defensive alliance between Great Britain and the States-general of the United Provinces was signed at the Hague in April, according to the tenor of which, each country was bound to succour the other, by sea and land, if attacked by any European power, and to guarantee each other in the possession of all their dominions. A similar treaty with Prussia, in which the conditions were similar, was signed at Berlin in August.

King's illness.—The mental disorder of the king could now be no longer concealed; and parliament, after an adjournment of fifteen days from the 20th of November, the day to which it had been prorogued, proceeded to make provision for the present or any future incapacity of the executive power; and, after keen debates, it was maintained by the minister, that in such cases it belonged to the houses of parliament to provide the means for supplying the defect of the personal exercise of the royal authority, while it was asserted by the opposition, that the heir-apparent had an indisputable claim to the exercise of the executive power in such cases.

Centenary of the revolution.—A century having elapsed from the important era of the revolution, that event was commemorated this year by extraordinary rejoicings in almost every part of the kingdom. In Dublin, the birth-day of king William was observed with great solemnity.

1789.—The regency-bill was the first subject of parliamentary consideration; and, after long discussion, the conditions and restrictions being agreed to, committees were appointed by the two houses of parliament to present their resolutions to the Queen and the prince of Wales, whose answers implied their acceptance of the trust to be reposed in them. But while the matter was under discussion, the king's recovery interrupted farther proceedings. The national rejoicings on this occasion exceeded every thing of the kind before known; most splendid illuminations were exhibited throughout the kingdom; a day of general thanksgiving was appointed; and the king in person, attended by the royal family, the great officers of state, and both houses of parliament, went in grand procession to St Paul's.

1790.—*French Revolution.*—The enlightened principles which at first seemed to actuate those concerned in the French revolution, produced corresponding sentiments in the liberal minded, who could, at a distance, calmly contemplate that extraordinary event. In Britain, it was hailed as the era of freedom to an oppressed people; the period of its commencement was celebrated with great triumph in many parts of the kingdom; and the views which it held out, and the rights which it maintained, became the topics of keen and violent controversy, both in conversation and writings. Mr Burke's celebrated work, "Reflections on the French Revolution," and "Paine's Rights of Man," contributed not a little to inflame the zeal of those who took opposite sides of this important question. But whatever were the opinions entertained at the time, the issue of that tremendous struggle holds out an awful warning to mankind of the dangers of popular commotion, excited and encouraged by evil passions, and followed by tumult, bloodshed, and death.

The States-general of France was opened at Versailles on the 5th May of the preceding year, and, on a dispute of some points of form, was soon resolved into the *national assembly;* the Bastile was stormed by the Parisians on the 14th of July; a declaration of rights, as the base of the new constitution, was agreed to, and passed in August; an insurrection broke out in Paris and Versailles, from which the royal family with difficulty escaped, and was attacked by a mob. France was divided into departments,—the distinction of orders was abolished,—tithes, and all ecclesiastical property were resumed,—monastic institutions were suppressed, and new courts of justice with trial by jury established. In the present year, the assembly passed a decree abolishing all hereditary titles, and every other mark of distinction of ranks in society; the general confederation, as it was called, was celebrated on the anniversary of the taking of the Bastile, when oaths of fidelity to the new constitution were administered to the king and the whole national assembly; the same solemnity was observed throughout the kingdom; a similar oath was imposed on the clergy, but almost the whole of the episcopal order, and a great number of the inferior clergy declined it; and, to avoid the penalties by which it was sanctioned, numerous emigrations took place.

The affairs of France, in consequence of the dreadful political storm which had been long gathering, excited great interest and diversity of opinion in this country; and in the speech from the throne, at the opening of parliament in January, an expression of regret was introduced for the internal commotions which disturbed the tranquillity of different parts of Europe. The subject of the French revolution soon after came before the house, and while it was spoken of in terms of approbation by one party, it was reprobated by another, and particularly by Mr Burke, who, in a most eloquent harangue, pronounced a severe censure on the principles and conduct of that event.

Nootka sound.—A dispute with the Spaniards concerning their exclusive claim to a navigation of the South seas, and their right to a settlement at Nootka sound on the coast of California, and, as a consequence of these pretended rights, the seizure of two English vessels by a Spanish frigate, led to serious hostile preparations. Vigorous exertions for war were made on both sides; but the dispute was adjusted by a convention, in which Spain agreed to the restoration of the settlement, reparation of the injury sustained, and to a free navigation and fishery in the Pacific ocean and South sea by British subjects

1791.—Among the earliest proceedings of parliament this year, a bill for the relief of the English Roman catholics passed into a law; but a petition from the general assembly of the church of Scotland, for a repeal of the test acts, as far as regards the members of that church being required to take the sacrament according to the form of the church of England, before admission to public offices, was rejected by a great majority. New regulations for the government of Canada, by which that province was divided into two districts, the Upper and Lower, were adopted; the slave trade was again discussed; the war between Russia and the Ottoman Porte came under consideration, with a message from the king that the aspect of affairs between these powers rendered it a prudent measure to augment his naval forces; and a bill also passed for a new settlement at Sierra Leone, for the culture of sugar, and other tropical productions, by free negroes.

Riots at Birmingham.—The violence of party spirit was not at all diminished at this time. In some places, indeed, it burst forth with redoubled fury. The celebration of the anniversary of the taking of the Bastile, which took place in various places of Britain, produced a good deal of political rancour in the different parties who espoused or disapproved the measures of the French reformers, and at Birmingham it terminated in a destructive riot. The populace collected together in a great mob, and directed their ungovernable rage chiefly against the dissenters, some of whose meeting-houses and private dwellings were reduced to ashes. The house, books, and apparatus of Dr Priestley were totally destroyed; and this scene of tumult and misrule having raged four days, and spread to the neighbouring districts, was only suppressed by military force.

France.—The system of revolution in France proceeding with unabated violence, became an object of great solicitude to surrounding nations. Emigrations continued from that distracted country; many members of the royal family sought an asylum in a foreign land; the king, queen, and their party escaped from the Thuilleries, but were seized at Varennes, and conducted back under an escort of the national guard; the constituent assembly dissolved itself, after decreeing that none of its members should be eligible to next assembly; popular societies were assuming a dangerous influence, of which the famous Jacobin club became the most conspicuous, and finally an instrument of the most violent faction; and an emigrant army, under the prince of Condé, was assembled on the German frontiers.

1792.—At the opening of parliament in the end of January, a confident hope was expressed, in the speech from the throne, that the state of Europe, and the assurances received from foreign powers, promised a continuance of tranquillity to this country; and the financial statement presented to the house of Commons, from which it appeared that the permanent income would exceed the permanent expenditure, including the annual million for extinguishing the national debt, by L.400,000, exhibited a flattering prospect of the national prosperity. The question of the abolition of the slave-trade was again agitated in parliament, and the motion for a gradual abolition was carried by a majority; but in the house of Lords the measure was less cordially received, and a committee being appointed for hearing evidence of the subject, no definite period could be fixed for its decision.

Reform societies.—A society under the name of the "Friends of the People," was established in the metropolis, for the purpose of promoting a reform of the parliamentary representation; and a notice being given in the house of Commons that the objects of the society would be brought under their consideration in the ensuing session, it was opposed by the minister, and all those who thought it highly inexpedient and dangerous, with the example of the French revolution before them, to yield in any point to a spirit of innovation. A royal proclamation was issued for preventing seditious meetings and publications, and prosecutions were commenced against many persons for circulating obnoxious publications.

Affairs of France.—Austria and Prussia had now determined to invade the French territories in support of Louis and the royal authority; and the duke of Brunswick, at the head of the combined armies, published two declarations in July, which produced a strong sensation in France. The deposition of Louis was proposed in the assembly; the fury of the populace rose to a high pitch; the palace of the Thuilleries was attacked on the 10th August; the Swiss guards were overpowered, and either fell in the struggle, or were massacred in cold blood, and every person who was an object of suspicion or hatred to a desperate mob fell a sacrifice to their savage fury; the royal authority was revoked or suspended; and the king and queen were confined in the Temple. But when the dreadful tocsin was sounded on the 2d September, a scene of massacre and bloodshed, which has scarcely had a parallel, was exhibited. Some priests doomed to banishment were the first victims; and on this and the following day more than one thousand persons, detained under suspicion, were assassinated. The abolition of royalty was voted in the national convention; and, under the assumed form of a republic, the very frame of society seemed to be broken down; the common terms of respect, and all distinctions in society, were laid aside; and the ordinary courtesies of polished life were treated with contempt. In the meantime, the French armies were successful in defending their territory; and the battle of Jemappe, gained by Dumourier, gave them the command of the Netherlands. The period was now approaching when Britain was no longer to be a passive spectator of these events; the deposition of Louis occasioned the recal of the British ambassador; the free navigation of the Scheldt being declared by the French, the English ministry made an offer of assistance to the Dutch; proclamations were issued to suppress seditious meetings; and, in the king's speech to parliament, which met in December, the necessity of augmenting the naval and military forces was declared.

East Indies.—The war with Tippoo sultan, which had proceeded with various success in the former year, was brought to a conclusion about the commencement of the present. Lord Cornwallis, with his allies, having appeared a second time before Seringapatam, and having succeeded in an attack on Tippoo's camp, he completely invested the capital. The siege was vigorously pushed, and the sultan, from the desperate situation of his affairs, was compelled to submission, by ceding half his dominions to the allied powers, paying a large sum of money by way of indemnities, releasing all the prisoners, and delivering his two eldest sons as hostages for the performance of the conditions.

1793.—The trial of Louis, for which preparations were made in the end of last year, and the condemnation and public execution of that unfortunate monarch on the 21st January, excited the strongest sentiments of abhorrence in Britain towards the French republic; and an order was issued from his majesty for the departure of the French ambassador from the kingdom within eight days. War was declared by the national convention against England and Holland on the 1st February; and Dumourier, with the view of penetrating into Holland, made an unsuccessful attack on the fortress of Williamstadt, which was defended by a detachment of English guards, and some Dutch and English gun-boats. After various military movements, the consequence of which was the recovery of the Austrian Netherlands from the French, Dumourier, who had meditated a plan for effecting a counter-revolution, went over with a small body of troops to the Austrian general Clairfait. His successor, Dampierre, in the command of the French army, attacked the Austrian and Prussian posts, which were supported by the British troops under the duke of York, and was repulsed. Valenciennes was then invested, and surrendered in July; the duke of York proceeded to Dunkirk in August, and laid siege to that town; but the want of naval co-operation, and the delay in the arrival of his heavy artillery, gave the French time to collect a powerful force, on the approach of which he was obliged to raise the siege.

While these and other offensive operations were carrying on against France from without, she was torn with the most furious dissensions and violence of contending parties at home; and scenes of the most ferocious cruelty and savage barbarity were daily exhibited, in the murders and executions of those who espoused opposite interests, and were denounced enemies of the republic. Among other victims was the queen of France, who, after being treated as the meanest criminal, during a long imprisonment of ten weeks, was guillotined on the 26th October; 21 deputies soon after suffered the same fate; and to these was added the execution of the duke of Orleans, of infamous character, and who voted against the life of the king, and of the celebrated Madame Roland, the wife of the minister. The formation of a new calendar was another remarkable feature in the spirit of innovation which guided the proceedings of the convention. It seemed to be the object of these who constructed it to obliterate the memory of Sundays, and to retain no allusion to any former religious observances.

Military operations.—Early in the year the British army and navy was actively employed against the French colonies in the West Indies; and soon after the intelligence of the declaration of war reached India, all their possessions on that continent yielded to the arms of Britain.

1794.—The vigorous prosecution of the war was strongly recommended in the speech from the throne at the opening of parliament. Beside the financial arrangements, for which a supply of nearly 20 millions was calculated, the subject of the war, the raising of the volunteer force, which had been recommended by the ministry, the subsidiary treaties with foreign powers, the suspension of the *habeas corpus* act, and proposals from the opposition for negociating with France, with the view of terminating the war, were the topics of much parliamentary discussion. The case of Muir and Palmer was also brought before parliament. They had been convicted of sedition in Scotland; but the sentence of transportation was thought too severe, and excited pretty general commiseration.

Trials for treason.—A bill of indictment was found against thirteen members of the reforming societies. Hardy, the secretary of the society, was first brought forward, and, after a trial of eight days, was pronounced *not guilty*. The trial of Horne Tooke, and of Thelwall, which successively followed, had a similar issue.

France.—The French were generally successful in their progress in the Netherlands against the allied forces, and by the end of July the whole of Austrian Flanders and Brabant fell under their dominion. On the German borders, the issue of the campaign was not less prosperous to the French republic; and before the close of the year, the invasion of Holland became the great object of their hostile movements. On the Spanish frontier their arms were also victorious; and in Italy they defeated a combined force of Austrians and Sardinians, beside gaining other material advantages. But in their domestic affairs the same ferocious spirit marked all the actions of those who held the reins of government. The noted Robespierre, along with two others, had now the uncontrouled sway of the executive power. Daily executions now took place, among whom were one of his colleagues, accused of a conspiracy, and the princess Elizabeth, sister of the late king, against whom some frivolous charges were made; but a party in the convention at last rose up against his intolerable tyranny, and he was seized, condemned, and executed, amidst the execrations of the people.

West Indies.—Martinique, after a vigorous resistance, was reduced by the forces under the command of Sir Charles Grey, and the fleet under Sir John Jervis. The island of Guadaloupe, with its dependencies, was brought to capitulation, and St Lucia also surrendered; but in consequence of the ravages of the yellow fever among the British troops, and the succour sent from France, Guadaloupe was recovered, and fell under the dominion of its former masters.

Lord Howe's naval victory.—Eager to dispute the sovereignty of the sea, the French had made great exertions for the equipment of a powerful fleet in Brest harbour, where it had been blocked up by the Channel fleet, under Lord Howe, for some time. During his absence from the station about the middle of May, an opportunity offered of putting to sea; and it was not till the 28th of the month, that the British fleet came in sight of the enemy off the coast of Britany. After some partial actions, Lord Howe gained the weather gauge, and with 25 ships of the line attacked the French fleet, consisting of 26 ships of the line. The French waited the onset with great steadiness; but in less than an hour after the centre was engaged in close action, their admiral, who was opposed to the British commander in the Queen Charlotte, aware of the issue of the contest, went off with crowded sails, and was followed by most of his van who were in a condition to carry canvas. One of the French ships went down during the action; and of her crew, who, in the ardour of enthusiasm, were heard shouting *vive la republique*, at the moment they were sinking into a watery grave, not one man was saved. Seven ships were captured, but one of them sunk almost as soon as she came into the possession of the victors. The carnage on board the French fleet was dreadful, for the amount of the killed and wounded in the captured ships alone was 1270. The loss of the British was stated at 904. This splendid triumph was received at home with the warmest congratulation, and celebrated with great rejoicings.

1795.—The parliament met on the 30th December of the preceding year, and the speech from the throne recommended a vigorous prosecution of the war. After the usual debates on the address, a motion was made on the 5th January for a repeal of the act suspending the *habeas corpus* act, and a warm discussion of the measure followed. This motion being negatived, a bill for continuing the suspension was moved for, and carried by a great majority. The first important measure brought before the house, was a plan for the augmentation of the navy. The number required for the service of the present year was calculated at 85,000 seamen and 15,000 marines; and to raise the deficient number expeditiously, without pressing, it was proposed that a certain proportion of men should be furnished by each merchant ship according to its tonnage, and every parish in the kingdom was to contribute a man. A loan of four millions was granted to the emperor of Austria, to enable him to carry on the war. The statement of the expenditure for this year, laid before the house on the 23d February, amounted to L.27,145,000, and the deficiencies of ways and means, estimated at L.400,000, were made up by new taxes, and an abridgement of the privilege of franking letters.

The trial of Mr Hastings, protracted for seven years, was concluded on the 23d April, by the sentence of the house of Lords, by which he was acquitted of all the charges. The expences of the trial, exceeding L.70,000, were paid by the East India company. A message from the king, delivered to the house of Commons on the 27th of the same month, recommended a suitable provision to be settled on the prince of Wales, who was married on the 8th to Caroline, daughter of the duke of Brunswick. An act was passed fixing the annual revenue of L.125,000, besides the rents of the duchy of Cornwall, estimated at L.13,000; but out of this income the sum of L.73,000 was appropriated to the discharge of his debts.

The emancipation of the Irish Roman catholics, and their restoration to the full privileges of citizens professing the protestant faith, became the subject of warm discussion in the Irish parliament; and the refusal of the English government to accede to their demands excited great discontent, which at length broke out into open rebellion. Lord Fitzwilliam, who was favourable to the measure, was removed from the government of Ireland; a disposition to riot appeared, and tumults arose, the suppression of which required military interference.

The conquest of Holland, a favourite object with the French, seemed now facilitated by the prevailing disaffection throughout the United Provinces to the house of Orange and its allies. During a severe frost in the end of December, a large French army marched over the ice of the Waal; but they were repulsed by 8000 British troops, and forced to recross the Waal with considerable loss. This success was only temporary, for their numbers being increased they effected their passage, and obliged the British forces to retire. The retreat of the British army after being attacked, and having lost their camp equipage, was most disastrous. Without the least shelter during a severe frost, and a heavy fall of snow, in the middle of January, they marched across a barren heath, while they were harrassed by the pursuing enemy and the hostility of the inhabitants. The French took possession of Utrecht and Rotterdam, and were soon after formally invited to Amsterdam, where they were received with general acclamation; the Stadtholder, deserted by all, with difficulty escaped, and, having embarked with his son in an open boat, reached Harwich on the succeeding day, and sought an asylum in England.

The annexation of Holland to the interest of France, was soon followed by a peace between the republic and Prussia; Spain, drained of her resources, also sued for peace on terms dictated by the French; and, in the month of June, a British squadron landed 3,000 men in Quiberon bay. They were chiefly composed of emigrant troops, and being attacked by the republican general in the night, the greater part were killed or taken prisoners. Among the latter was the count Sombreuil, an amiable young nobleman, who, with the bishop of Dol and many others, was sentenced to suffer death, and was shot at Vannes.

Early in this year a deep laid scheme for producing a general revolt against the British government in the French islands in the West Indies was attempted to be put in execution, by means of emissaries among the negroes and people of colour; but, after a severe struggle, it was finally defeated in Grenada, Dominica, and St Vincent. The Dutch colony of the Cape of Good Hope surrendered to the fleet and army under Sir G. Keith Elphinstone and general Craig, on the 23d of September.

Considerable discontent appeared among the populace, especially in London, excited, it was supposed, by the scarcity of provisions, the cruel practices of crimps employed in the recruiting service, the successes of the French, and the defection of the allied powers. The ministers, and the supporters of the war, became unpopular; reforming societies were full of activity; and the king, on his way to parliament, was assailed with clamorous demands for peace, and one of the glasses of his coach was broken by a bullet.

1796.—Before the close of the session of parliament in May, the discussion of the taxes which were necessary in consequence of the unusual introduction of two loans in the same session, which, together, amounted to twenty-five and a half millions, formed the most prominent feature in their proceedings.

In the important events which took place in the course of this year, Britain had no direct share. An insurrection against the new British government in Corsica broke out in October; and the garrison, deeming itself unequal to an effectual resistance, embarked in the ships in the harbour, and retired to the isle of Elba. War was declared against Great Britain by the Batavian republic in May, and by Spain in October. In the East Indies, the Dutch settlements in Ceylon, Amboyna, and Banda, submitted without resistance to the British troops, in the end of last year and the beginning of the present. Grenada, in the West Indies, was recovered from the insurgents, and St Lucia was reduced; and the Dutch settlements in Demarara and Essequibo acknowledged the same authority. A fleet of Dutchmen, consisting of three ships of the line, three frigates, and some smaller vessels, with two thousand troops on board, which had sailed from Holland for the recovery of the Cape of Good Hope, was captured by the British squadron, without opposition. A negociation for peace was entered into with the French directory, and Lord Malmesbury was sent to Paris in October on that business; but, after a great deal of discussion, his mission failed. The supply required for this year was stated at nearly twenty-eight millions. Towards the close of the year, great alarm prevailed of an invasion of some part of the coast of Britain by the French. An armament was equipped at Brest, consisting of 25 ships of the line and a number of frigates, with transports for 25,000 men. When the fleet sailed, in December, some of the largest, on leaving the harbour, were driven on the rocks, and lost. The fleet being dispersed by a violent storm, only seven ships of the line and ten others reached Bantry bay, in the south of Ireland, on the 24th of December; and as general Hoche had not arrived, the fleet, after being some days in the bay, returned to France, with the loss of two ships of the line and three frigates. The death of Catherine II. whose reign forms one of the most brilliant periods of Russian history, and the retirement of general Washington from public life, may be enumerated among the events of this year not altogether unconnected with the affairs of Britain.

1797.—Great Britain had now become a principal in the war, and the desertion of her allies compelled her to fight for her own security. Lord Malmesbury's unsuccessful negociation cast a deep gloom on the prospects of the country, and produced an unusual depression of the funds; and a strong sensation was produced by the suspension of cash payments by the bank of England, arising from the large advances of foreign subsidies. From an investigation of the affairs of the bank by a secret committee, it appeared, that a surplus property of nearly four millions beyond the amount of their debts, beside a permanent debt from government of more than eleven millions, remained. Various regulations were made on this subject; and a bill was passed to continue, for a limited time, the restriction of the issue of specie.

In the early part of the year, a splendid naval victory was achieved, and exhibited a striking example of the superior skill and bravery of British seamen. Spain had made great exertions in equipping a fleet, for the purpose of making a junction with the French squadron at Brest; and a powerful armament, composed of 27 sail of the line, six of which mounted 112 guns, and one 136 guns, but having a large proportion of landmen on board was indifferently manned, was attacked on the 14th February by admiral Jervis, whose fleet consisted of only fifteen ships of the line and some frigates, but he was well supported by brave and skilful officers and experienced seamen. Cruising off Cape St. Vincent, in Portugal, he descried the Spanish fleet, bore down upon it, and cut off one-third of the line. The attempt of the Spanish admiral to rejoin his separated ships, was defeated by commodore Nelson, and victory soon decided in favour of the British, who took four ships of the enemy, one of which carried 112 guns. As a reward for this service, the admiral was ennobled, and received the title of Earl St. Vincent, and Nelson received the honour of knighthood. The island of Trinidad, in the West Indies, was about this time reduced to the dominion of Britain; but an attack on Porto Rico was unsuccessful.

In the same month, a singular armament was fitted out at Brest, and made its appearance on the coast of England; it consisted of four vessels, three of which were large frigates, and with 1400 men on board. They entered the British channel, anchored in a bay near Fishguard in Pembrokeshire, and landed the soldiers. The alarm was given, and Lord Cowdor placed himself at the head of more than 3000 men, who were soon collected from all quarters. The invaders immediately agreed to surrender as prisoners of war, and next day laid down their arms. The purpose of this singular enterprise was never explained; many of the men were in rags, and seemed to have been just taken from prison.

A serious mutiny in the British navy excited great alarm in the nation in the early part of this year. The smallness of their pay, and of the Greenwich pensions, the unequal distribution of prize money, the severity of naval discipline, and the haughty conduct of their officers, were the chief subjects of complaint among the seamen. In February and March, anonymous petitions from several of the ships companies in the channel fleet of Lord Bridport, praying for relief, were transmitted to Lord Howe, who, on enquiry, was assured that no general discontent prevailed in that fleet; but on its return to Portsmouth, an unanimous agreement was entered into, that not an anchor should be lifted, till full redress of their grievances was obtained; and on the 15th April, when the signal for sailing was hoisted, the mutiny was declared by three cheers from the Queen Charlotte, which were answered by the rest of the fleet. Delegates were appointed from each ship's company, who held their deliberations on board the Queen Charlotte; an oath was administered to every seaman to stand firm to their purpose, the more obnoxious officers were sent on shore, but otherwise strict discipline was observed; and a petition to the Admiralty, and another to the house of Commons, stating the nature of their complaints, were presented. The board of Admiralty was removed to Portsmouth, and a negociation was entered into; but order was not restored till Lord Bridport went on board, and assured them that their grievances were redressed. A fresh mutiny broke out on the 7th May, on a suspicion among the sailors that the promises made to them would not be kept; but by the prudent interference of Lord Howe, it was fortunately quelled. On the following day, an estimate was laid before the house of Commons for the augmentation of pay to the seamen and marines of the navy, and the sum required was stated at L.436,000; and a bill introduced for this purpose was passed into a law.

But these concessions were not altogether satisfactory, for, on the 22d of May, a mutiny of a still more alarming nature broke out in the men-of-war lying at the Nore; they were afterwards joined by four ships from admiral Duncan's fleet off the coast of Holland. Delegates wese elected, and a statement of their grievances was drawn up and presented to the Admiralty, but their demands were refused; and Parker, a person of some education and determined character, declared that the seamen would keep possession of the fleet till their grievances were redressed. An offer of pardon to bring back the men to their duty being unsuccessful, it was determined by government to reduce them to subordination by force. While preparations were making for this purpose, by taking up the buoys at the mouth of the river, and erecting batteries on the banks, a proclamation, declaring the

Civil history. ships in a state of rebellion, and prohibiting all intercourse from the shore, was issued. At the same time the mutineers became disunited among themselves; ship after ship deserted their cause; and at last all the ships having submitted, Parker and the other delegates were given up. He was tried by a court-martial, capitally convicted, and executed, along with some of his associates; and this alarming state of affairs was terminated by a general pardon to the other offenders.

In July, an attack made on the town of Santa Cruz, in Teneriffe, under the command of admiral Nelson, was most disastrous. Of a thousand men who landed on the mole, nearly the whole were killed or wounded, and the commander himself lost his right arm.

The arms of the French republic were eminently successful, to whatever part of the continent they were directed; the Pope was compelled to conclude a pacification on their own terms; peace was entered into with Austria; Venice was reduced to the condition of a province of France; and the state of Genoa fell under the protection of the same power.

On the 11th of October, admiral Duncan, with 16 ships of the line, attacked the Dutch fleet, of 11 ships of the line, and four of 56 guns, between Camperdown and Egmont, on their own coast, and, after a severe engagement, obtained a complete victory, having captured eight ships of the line, two of 56 guns, and two frigates, with the admiral and vice-admiral of the fleet. The news of this brilliant success was followed with great rejoicings, and the British commander was rewarded with a peerage.

1798.—The discontents in Ireland, which had continued for some time, at last broke out into open rebellion, and a general insurrection was planned, according to which it was determined to seize the castle of Dublin, the camp near it, and the artillery, at the same time. This plot was defeated by the information of one of the conspirators. The rebels flew to arms, with 15,000 men made themselves masters of Wexford on the 30th May, were repulsed at New Ross, and their main body, posted on Vinegar Hill, was attacked by general Lake on the 21st of June, and totally routed. A similar insurrection was attempted in the north, but was soon suppressed. Lord Cornwallis, on account of his political and military talents, was appointed to the government of Ireland soon after these events, and by his moderation and prudent conduct the quiet of the country was restored. But the landing of 900 regular French troops under General Humbert, on the west coast of Ireland, in the month of August, from three French frigates, threw the country again into disorder. General Lake opposed their progress at Castlebar, but was compelled to retreat. The French, and some Irish malcontents who had joined them, crossed the Shannon, and while Lord Cornwallis was advancing with more troops, general Lake, who continued to watch the movements of the enemy, came up with their rear on the 8th September, and, after a short action, compelled them to surrender. In the following month another attempt of the French to invade Ireland was not more successful. A ship of the line, and eight frigates, with troops and ammunition on board, appeared off the north-west coast; and on the 12th October, Sir John Borlase Warren captured the former, and, three of the latter; and excepting two frigates, the whole fell into the hands of the British. Civil history.

Among the proceedings of parliament, a bill passed for increasing the assessed taxes; a plan was introduced for extinguishing part of the national debt, by allowing individuals to purchase their land tax; and, in April, a new estimate for the public supplies was proposed, and the sum required amounted to nearly twenty-eight and a half millions. A loan of fifteen millions for Great Britain, and two millions for Ireland, and some new taxes, were among the ways and means. Connected with military affairs, an enactment was made for allowing men in the supplemental militia to inlist into the regular army; and by another law, permission was given to the militia regiments to extend their services to Ireland.

The French having over-run a great part of the continent, and almost all opposition to their overgrowing power having terminated by the treaty of Campo Formio, they were eager to humble and reduce Britain to the same abject state. For this purpose troops were collected on the opposite coast, and, in allusion to its destination, it was called the Army of England, and transports were fitted out in the harbours of the channel to convey the troops to the shores of Britain. Whether all this hostile preparation was merely intended to excite alarm, or whether it had any serious object in view, the most active measures were adopted to repel the threatened invasion. The militia was increased; bodies of the regular cavalry were raised among the yeomanry; and volunteer infantry were embodied and trained throughout the kingdom. A bold attack was made on the enemy's coast in the month of May, by a number of vessels and a body of troops under the command of captain Home Popham and general Coote, for the purpose of destroying some transport-boats at Flushing, which were to be employed in the invasion. The troops landed to the eastward of Ostend, blew up the sluices of the canal, and destroyed a number of vessels; but on returning, the violence of the surf prevented them from re-embarking; they were attacked by a superior force, and compelled to surrender.

The Swiss cantons, after a spirited resistance to the aggressions and inroads of the French, were finally obliged to submit to their invaders, and the whole were formed into one republic, dependent on France. The castle of St Angelo at Rome was seized in February by a body of French troops. The pope was at first confined to the Vatican under a strong guard. Being informed that his civil power was at an end, and that his spiritual dignity only remained, he withdrew to Sienna; and Rome, for several months, became a dreadful scene of tumult, plunder, and bloodshed. An expedition, which had been long in preparation at Toulon, sailed, under the command of Bonaparte, on the 20th May; reached Malta early in June, and took possession of the place, not without suspicion of previous concert; and on the 1st of July arrived off the coast of Egypt, which was the ultimate object of its destination. A strong squadron, under the command of admiral

Nelson, was appointed to watch the motions of the French fleet; but it was not till the 1st August that he discovered it at anchor across the bay of Aboukir, near the mouth of the Nile. The French fleet, commanded by admiral Brueys, consisted of 13 ships of the line, one of which, L'Orient, carried 120 guns, and four frigates. The English fleet included an equal number of ships of the line, and one of 50 guns. The French squadron was moored in line-of-battle, and protected by shoals and batteries; but this advantageous position produced no hesitation in the prompt and gallant Nelson to decide on an immediate attack. A close engagement commenced; and before night several of the French ships had struck their colours. During the darkness, a most terrific scene was exhibited in the conflagration of the L'Orient, which was followed by a tremendous explosion, in which the French commander and his whole crew, exceeding 1000 men, perished. The action closed next morning; nine sail of the line were captured, and two more, with two frigates, were destroyed. This splendid victory was celebrated in Britain with extraordinary rejoicings, brought new honours to the hero by whom it was achieved, and spread the fame of British valour all over Europe.

1799.—At the close of the preceding year, the requisite supplies for the public expenditure were estimated at L.29,272,000. A plan of an income tax for raising a considerable part of them within the year was proposed. The discussions of this measure were continued at the commencement of the present year, and the resolutions submitted to the house were, in substance, that the augmentation of the assessed taxes should be repealed, and a duty of 10 per cent upon income substituted, to commence with incomes above L.60 a-year, but in a reduced ratio from that sum to L.200. The national income was calculated at L.102,000,000, from which a tax of ten millions was expected. A bill was brought in for this purpose, and passed into a law. The union of Great Britain with Ireland, which was finally arranged this year, was one of the most important legislative measures of the session. The French made many very important movements in the early part of this year, in Germany, Switzerland, and the north of Italy; but they met with a very efficient opposition from the celebrated Russian general Suwarof, at the head of 60,000 men; he defeated them at the battle of Novi in Italy on the 10th August, marched into Switzerland in the following month; but after a severe action with Massena, he was compelled to retreat with great loss; and after various movements, in which he discovered the talents and bravery of a great general, he was recalled; and, for the present, the powerful co-operation of Russia in the common cause terminated.

But in consequence of a concerted plan between the courts of London and Petersburgh, a descent on the Dutch coast was projected. An expedition under Sir Ralph Abercromby arrived at the Helder on the 27th, and took possession of the fort, which was abandoned by its garrison. The fleet, consisting of eight ships of the line, three of 54, and eight of 44 guns, with seven small ships and four Indiamen, surrendered without resistance; but, on the 10th September, the British forces were attacked by 25,000 French and Bavarian troops, and repulsed with considerable loss. The duke of York assumed the chief command on the 13th, and with an army of 35,000 men, of which 17,000 were Russians, a general attack, which was made on the 19th, was unsuccessful; but with an accession to his force, he renewed the attack on the 2d October, and defeated the French with severe loss. On the 6th an attempt was made to force the position to which the French had retreated, but it failed; and as the inhabitants shewed no disposition to second the efforts of their deliverers, it was determined to abandon the enterprise; a suspension of arms was proposed and agreed to, on condition that the prisoners on both sides should be given up; and as an equivalent for permission to the British to reimbark without molestation, 8000 seamen, Dutch or French, who were then prisoners in England, should be liberated. In August of this year, the Dutch colony of Surinam surrendered to the British arms.

Important transactions took place in the East Indies during this year. The restless Tippoo Sultan, jealous of the encroachments of the East India company on his power and territory, had entered into negociations with the French and with the Nizam of the Deccan in the preceding year, and had also sent an embassy to the king of Cabul, for the purpose of forming a coalition against the British. Some correspondence had taken place between him and Bonaparte when the latter arrived in Egypt, while the former had been gradually increasing his military establishment. The views of Tippoo, and his warlike preparations, were not unknown to the governor-general, who being disappointed of an amicable termination of the differences, resolved to attack the sultan in his capital. General Harris, with the native and British troops, entered the Mysore country in March. On the 30th April, Seringapatam was invested, and the cannonading having continued for several days, was stormed on the 4th May, when a dreadful conflict ensued, and Tippoo lost his kingdom and his life. His territories were divided, part was assigned to the English, part to the Nizam, and a sovereignty was restored to a descendant of the ancient rajah of Mysore, who had been dispossessed by Hyder Ally, the father of Tippoo.

1800.—In promoting his ambitious views, Bonaparte abandoned his army in Egypt, and on his return to Paris succeeded in introducing a new form of government, at the head of which he found means to place himself in the character of First Consul. One of his first acts connected with this country was, to address a letter, which he said was entirely confidential, to the king of Great Britain, for the purpose of entering into a negociation for a general peace. The sincerity of his sentiments was justly doubted at the time, and his future conduct, as well on the present as on other occasions, fully confirms the suspicion. An official answer in general terms was returned by the secretary of State, who declared that as soon as security was given by the French for the repose of Europe, his Majesty would not be slow in concerting with his allies the means of a general pacification; but as no such security appeared at present, he was resolved, in conjunction with the other powers interested, to prosecute the war with vigour. In answer to this letter, a note was returned by Talleyrand, who proposed a suspension of hostilities, and the appointment of plenipotentiaries on both sides, to hold a conference for the adjustment of the differences between the two nations. The correspondence terminated with Lord Grenville's reply.

The subjects of discussion in parliament were, the vigorous prosecution of the war; the correspondence with the French government for negociating a general peace; an enquiry into the failure of the late expedition to Holland, which was suppressed; the great increase of the national expenditure, for which the supply required was stated at the enormous sum of thirty-nine and a half millions, and for which a loan of eighteen and a half millions was part of the ways and means; and the final conclusion of the proposed union of Great Britain and Ireland. The scarcity of corn, which had risen to a higher price than had been known at any former period, and the means of alleviating the severe distress which it occasioned, became also the topics of parliamentary investigation. A bill was passed, prohibiting the sale of bread which had not been baked 24 hours, and the members of both houses resolved as much as possible to diminish the use of bread and flour in their own families. The same example was imitated by the higher ranks throughout the kingdom; but as the produce of the harvest was still deficient, parliament met early in November, and various acts were passed for continuing the restrictions upon the consumption of grain, and for encouraging importation. A bill was also passed to ascertain the population of the kingdom.

1801.—On the first of January a proclamation was issued, relative to the titles and armorial ensigns belonging to the imperial crown of Great Britain and Ireland; and to mark the era of the union with Ireland, new titles were conferred on some of the nobility of that country, and several of them were created peers of the united kingdom.

A confederacy having been formed by the northern powers, for the purpose of annulling or diminishing the naval dominion which Great Britain had arrogated to herself, an embargo was laid on all the ships in British ports belonging to these powers, and letters of marque were issued for the capture of their vessels at sea; and after some correspondence, as a measure of retaliation, a similar embargo was put on the shipping of Great Britain in the ports of Sweden and Denmark. To settle the point in dispute, a squadron of 18 ships of the line and four frigates, beside bomb-vessels and gun-boats, was dispatched to the Baltic, under the command of admiral Parker, and vice-admiral Nelson. The most vigorous preparations were made by Denmark to resist this force; the whole Danish fleet were stationed in the road of Copenhagen, and was strongly supported by floating and land batteries. But the onset, headed by Nelson, with 12 ships of the line, and all the frigates and small vessels, was irresistible. While the battle yet raged, Nelson, certain of success, and anxious to save the lives of men, sent a proposal for a truce to the prince-royal of Denmark, and landed himself to settle the terms of conciliation. At this time 17 sail of the Danish line were either sunk, burnt, or taken.

The death of the emperor Paul, whose incoherent conduct indicated some degree of mental derangement, and rendered him unfit to manage the reins of government, gave a new aspect to the state of affairs in the north. His successor, Alexander, immediately liberated all the British seamen belonging to the ships sequestrated by his father; and after negociations between the courts of London and Petersburgh, all disputes were adjusted, and Sweden and Denmark acceded to the same terms.

An armament, destined for the recovery of Egypt, was prepared in the end of the preceding year, and being placed under the command of Sir Ralph Abercromby, arrived at Aboukir on the 2d March; experienced a vigorous resistance, and suffered a considerable loss when they landed on the 8th; and having advanced towards Alexandria, they encountered the French on the 13th in a smart and indecisive action. Before daylight on the 21st, an obstinate conflict took place, which terminated in the defeat of the French; but the loss of the British was considerable, and the commander himself was mortally wounded. General Hutchinson, who succeeded to the command, was reinforced by a body of Turks, the French retreated to Cairo, and the united army advancing, agreed to a capitulation on the 27th June, on condition that the French troops, with their arms and effects, should be conveyed to the French ports in the Mediterranean. Menou, the other French general, who had remained at Alexandria, refused to accept of the capitulation, and defended himself till the 27th August, when he offered to submit, and received the same terms; and thus Egypt was delivered from the attempt to reduce it to the state of a French province.

The resignation of Mr Pitt formed a prominent feature in the political administration of the country. His retirement from office was ascribed to his inability of redeeming a pledge which he had given to remove the restrictions from the Roman catholics of Ireland, in consequence of the insuperable objection of the measure being contrary to the king's coronation oath. But before he resigned his office, he submitted to the house his financial plans. The necessary supplies were stated at more than thirty-five millions and a half; to defray which, some new taxes, and a loan of twenty-five and a half millions, were proposed. A new ministry was formed, whose measures were first directed to secure the internal tranquillity of the country. The disturbances in Ireland required the renewal of the act for the suppression of rebellion in that country; and the proceedings of societies of disaffected persons in Britain, occasioned a revival of the act for preventing seditious meetings, while the suspension of the *habeas corpus* act was continued in both countries. During this session of parliament an act was passed, declaring clergymen ineligible to a seat in the house of Commons. This enactment had an immediate reference to the election of the celebrated Horne Tooke as member for Old Sarum.

To excite alarm in Britain, or for the more serious purpose of actual invasion, the First Consul formed encampments, which were occupied by chosen troops, on the opposite coasts of France and Flanders, and the combined French and Spanish fleet was collected in the harbour of Brest. These hostile preparations were not overlooked by Great Britain; a great military array was provided; the volunteer cavalry, and infantry frequently assembled for exercise, and was kept ready for immediate service; and the naval force of the empire blockaded the principal ports of the enemy, and kept the closest watch on all his movements.

Some naval actions, with various success, were fought this season. Two English frigates, and a man-of-war of 74 guns, were captured by Gantheaume's squadron in the Mediterranean; and the French squadron under admiral Linois, lying at anchor off Algeziras, was attacked by admiral Saumarez, one of whose ships of 74 guns, getting on shore near a battery, suffered so much by the enemies fire, that she was obliged to strike her colours; but in a succeeding action the week following, with the same French ships, reinforced by five Spanish ships of the line, admiral Saumarez captured one ship of 74 guns, while two of the Spanish ships, of 112 guns each, took fire and blew up. In the month of August, Lord Nelson, with a flotilla of gun-boats and other armed vessels, engaged in an enterprise against the harbour of Boulogne, with the intention of destroying the small craft intended for the invasion of England. The French were so well provided with every means of defence, that the daring courage and perseverance of British seamen, who suffered a considerable loss in killed and wounded, made little impression.

The preliminaries of peace between Great Britain and France were signed on the 1st October, and excited sentiments of satisfaction among the people of both countries; and in the beginning of the succeeding month Marquis Cornwallis was appointed ambassador plenipotentiary, for the purpose of negociating the definitive peace. Similar treaties between France and the Ottoman Porte, and France and Russia, soon followed.

1802.—The definitive treaty of peace between France, Spain, and the Batavian republic on the one part, and Great Britain on the other, was signed at Amiens on the 27th of March. But the First Consul of France, previously to its signature, had been appointed president of the Cisalpine republic, which now became an appendage of France, while Louisiana, the isle of Elba, and the duchy of Parma, by a private treaty with Spain, were annexed to the same power. The claim of the Prince of Wales to the arrears from the revenue of the duchy of Cornwall, which, after discussion, was thrown out; the financial arrangements, in which it was proposed to abolish the income tax, and to fund the sum with which it was charged, amounting nearly to fifty-six and a half millions, making the whole sum to be funded nearly ninety-eight millions, the interest of which, exceeding three millions, to be provided for by new taxes, and with a loan of twenty-five millions, which was also proposed; the national debt, which was estimated at five hundred millions; and very ample discussions on the terms of the treaty of peace, formed the chief topics for the consideration of parliament.

A conspiracy against the government was detected towards the close of the year. Colonel Despard, who had distinguished himself in a military capacity, formed a society composed of soldiers and some of the lower class of citizens, with the professed object of reform and extension of their liberty. He and six of his accomplices were tried, found guilty, and executed for high treason.

1803.—The aspect of affairs on the continent and the military preparations which were carrying on in the ports of France and Holland, were brought before parliament, by a message from the king, in the month of March; a resolution was passed, and soon after the militia was called out; and it was announced in May that the British ambassador, in consequence of the failure of the negociation, was recalled from France. War was at last declared, and great preparations were made for its vigorous prosecution. A most outrageous violation of the laws of hospitality was committed by the French government, in seizing all persons between eighteen and sixty years of age belonging to this country, who were then in France, and declaring them to be prisoners of war; a measure which was attended by most calamitous consequences, both to individuals and families; and some of those who fell under this misfortune remained in captivity during the war. The French were prompt and vigorous in their operations; they took possession of all the strong posts of the kingdom of Naples lying on the Adriatic; seized Hanover, and thus obtained the command of the navigation of the Elbe and Weser, from which British commerce was excluded; and, by extraordinary exertions, collected a large army and an immense flotilla at Boulogne, for the invasion of England. But the spirit of resistance to the threatened attacks of the enemy, which pervaded the country, increased the number of volunteer associations to such an extent, that in a short time not fewer than 300,000 men were trained to arms and ready for service.

In the West Indies, St Lucia, after the fort of Morne Fortunée was stormed, submitted to the British troops in May. Tobago surrendered, without resistance, to the same force; and the Dutch colonies of Demerara, Essequibo, and Berbice, were reduced in September. In the East Indies a very active warfare was carried on by the British, in alliance with the Mahratta sovereign of Poonah and with the nizam of the Deccan, against the Mahratta chiefs Scindia Holkar and the rajah of Berar; and the result of the military operations, which were conducted by general Wellesley, was the destruction of a powerful confederacy against the British, the annihilation of the French interest in India, and an extension of the British territory.

In the month of July, an insurrection broke out in Ireland, which, for a short time, excited considerable alarm, and which had in view the subversion of the government. The leader of this plot had collected a few arms, which were put into the hands of a desperate mob, for the hopeless purpose of seizing the castle of Dublin. A crowd of country people from the county of Kildare entered the capital, and, assembling in a tumultuous manner, were furnished with pikes and fire-arms; and having met with no opposition while they advanced through the principal streets, they were guilty of several atrocities; and at last meeting with Lord Kilwarden and his nephew in a carriage, they dragged them from it, and barbarously put them to death on the spot. But so feeble and ill-planned was the insurrection, that they were dispersed by 120 soldiers; and some of the leaders being taken, they were tried for high treason, convicted, and executed.

1804.—The mental disorder of the king appeared for a short time at the beginning of this year. Parliament was much occupied in consolidating and explaining the laws respecting volunteers; and a bill was passed for allowing the Irish militia to extend their services to Great Britain. A change of ministry took place in May; and Mr Pitt resumed his place of first lord of the Treasury and chancellor of the Exchequer.

Among the naval operations of this year, the spirited defence made by captain Dance, with a fleet of 15 Indiamen, 12 country ships, and a Portuguese Indiaman, against the French admiral Linois, with the Marengo of 80 guns, and some frigates, stands conspicuous. The French fleet were repulsed without making a single prize, and were actually pursued by the victorious merchantmen. The Dutch settlement of Surinam was reduced under the authority of Great Britain. In the month of October, a number of vessels, of a particular construction, and containing explosive materials, were sent in among the enemies small craft moored on the outside of Boulogne pier, but the effect produced was very inconsiderable.

The capture of three large Spanish frigates, loaded with treasure from the New World, was a most successful event. On the 5th October, captain Moore, with the Indefatigable and three other frigates, which had been dispatched for that service, and was cruizing off Cadiz, descried four large Spanish frigates steering for that port. The Spanish admiral being informed by captain Moore that he had positive orders to detain his squadron, returned no satisfactory answer. A close engagement commenced, and it had not continued more than ten minutes, when the Spanish admiral's second, La Mercedes, blew up with a dreadful explosion, and, with the exception of forty men, all on board perished in this terrible catastrophe, which, beside the melancholy loss of so many lives in an instant, was accompanied by an incident of a peculiarly afflictive nature: A native of America and his whole family, consisting of his wife, five sons, and four daughters, were passengers in the ship which blew up; the father and one of the sons had gone on board another ship before the action; and it is easier to conceive than express their anguish of heart, when they were thus doomed to see themselves in a moment deprived of all that was near and dear to them on earth. This act of aggression, without a previous declaration of war, was censured by some, while the capture was approved by others, on the ground that the rich treasure was destined for the service of the French, the avowed enemies of Great Britain.

With scarcely any thing short of the power of an absolute sovereign, the ambition of the First Consul of France now aspired even to the titles of royalty. After the preliminary forms, which met with little difficulty, a decree was framed and passed into a law, with the single dissenting voice of Carnot, by which the rank and title of Emperor of the French, were conferred on Napoleon Bonaparte, with hereditary succession of the same in his family; and the grand ceremony of the coronation of the emperor and empress of France, took place at Paris in November, with extraordinary magnificence, to which the presence of the pope, who was called from Rome to place the crown on his head, not a little contributed. Thus, many of the same individuals, who had solemnly sworn to maintain the inviolability of the republic, after the lapse of less than ten years, were called upon to swear obedience to the constitutions of the empire, and fidelity to the emperor.

In the course of this year, a pestilential disease broke out in the garrison of Gibraltar, and carried off many of the inhabitants and troops; and in December, the court of Spain published a declaration of war against Great Britain, alleging various acts of hostility, and particularly the attack and capture of the frigates.

1805.—The unsettled state of Ireland, and the existence of a committee of united Irishmen in Paris, required the suspension of the *habeas corpus* act in that country, which, after a keen debate on the subject, was passed. The rupture with Spain formed another topic of warm discussion in both houses of parliament. The charge of supplies for Great Britain and Ireland for this year, was stated at more than forty-four and a half millions; and among the ways and means, were a loan of twenty millions for England, and two and a half millions for Ireland, and several new taxes. In the month of April, a charge was brought against Lord Melville, first lord of the admiralty, of applying the public money to other uses than those of the naval department, and of conniving and participating in a system of peculation which had been practised in the office of pay-master of the navy; and after various proceedings in the house of Commons, his lordship, at his own request, acknowledged at the bar, that he had appropriated the public money to other public purposes, but without any benefit to himself, and without participating in the profits of others; and, at the same time, confessed that he had applied the sum of L.10,000, in a way which he could not reveal, consistently with private honour or public duty. An impeachment followed, and after his trial before the lords in Westminster hall, in the early part of the succeeding year, he was acquitted of all the charges.

The French emperor addressed a letter to the king of Great Britain, in which, probably with his usual sincerity, he expresses himself desirous of entering into pacific negociations with this country. The reply, which was not satisfactory, was published in France with comments, endeavouring to shew the determined hostility of the British court; and, at the same time, the most active preparations were made for the invasion of England. The flotilla at Boulogne was increased, and not fewer than 100,000 well disciplined troops, under the command of able generals, were collected in its vicinity.

Civil history.

Confederacy against France.—The boundless ambition and extensive influence of the French emperor, and the territorial possessions which he had acquired, or were subjected to his controul, naturally alarmed the other states of Europe. He had now assumed, at the pretended request of the States, the title and authority of king of Italy, and annexed the Ligurian republic to the French empire; and the proceedings of the Batavian republic afforded ample proof of his influence in framing their new constitution. The courts of London and Petersburgh, accordingly, entered into negociations for the purpose of adopting measures to resist the encroachments of the French government, and to secure the independence of the allied states; and, after a communication with France proposing a general pacification, Sweden and Austria joined the alliance.

Attack upon Austria.—Bonaparte, with his usual promptitude, prepared to attack Austria, and having broken up the greater part of his camp at Boulogne, and reinforced his army from other quarters, he proceeded by forced marches to meet the Austrians on the banks of the Danube; and such were the rapidity of his progress, and the success of his arms, that the strong post of Ulm surrendered, and the whole of the Austrian troops laid down their arms. Great alarm now prevailed for the safety of the capital; and the emperor of Germany having retired with his court from Vienna, the French entered it on the 13th November. The French were not less successful in Italy.

Battle of Austerlitz.—The main army of the allies, was composed of 50,000 Russians, with the emperor Alexander at their head, and of 25,000 Austrians, consisting chiefly of new levies. The amount of the French army was nearly 80,000 men, in the best state of discipline, and full of confidence from former successes. The contending armies met near the village of Austerlitz on the 2d of December, and fought a sanguinary battle, which is noted in history by that name, or distinguished by the name of the battle of the Three Emperors, from the sovereigns of Austria, Russia, and France being present.

Battle of Trafalgar.—The French fleet having eluded the vigilance of Lord Nelson, sailed from Cadiz with a body of troops on board for the West Indies. The British admiral, informed of their destination, pursued the enemy with an inferior force, and reached Barbadoes on the 4th June. But the French admiral declined to risk an engagement, and returned to Europe; Nelson pursued, but was not fortunate in coming up with the enemy. In a partial engagement with Sir Robert Calder, two ships of the line were taken from the French; Lord Nelson returned to England, sailed again from Portsmouth in September, and having taken the command of the fleet under admiral Collingwood, lying off Cadiz, he took measures for watching the motions of the enemy. The combined fleet, consisting of 33 sail of the line, of which 18 were French and 15 Spanish, sailed from Cadiz on the 19th October, steered towards the straits of Gibraltar, and were followed by the British fleet, composed of 27 ships of the line, which came up with them on the 21st, off Cape Trafalgar. Lord Nelson, with his usual skill, boldness, and promptitude, bore down in a double column on the enemies fleet, which was drawn up in the form of a crescent, brought them to close action, which was continued for four hours, and terminated in the capture of 19 sail of the combined fleet, with the French commander-in-chief and two Spanish admirals. The loss of the victors in this severe conflict exceeded 1500 men in killed and wounded; but the joy which the splendour of the triumph diffused over Britain, was not unmingled with the sincerest regret at the fall of the naval hero who had planned and executed this unparalleled enterprise.

1806.—*Death of Mr Pitt, and new ministry.*—The death of Mr Pitt on the 23d of January, two days after the meeting of parliament, was the first object of its attention. It was moved and agreed to in the house of Commons, that his remains should be honoured with a public funeral, a monument should be erected to his memory, and his debts, amounting to L.40,000, should be discharged by the nation. This event was immediately followed by the formation of a new ministry, with the arrangement of which Lord Grenville was entrusted. Lord Erskine was nominated lord Chancellor, Earl Fitzwilliam president of the Council, Viscount Sidmouth lord Privy-seal, Lord Grenville first lord of the Treasury, Lord Howick first lord of the Admiralty, Lord Moira master-general of the Ordnance, Earl Spencer, Mr Fox, and Mr Windham secretaries of State, Lord Henry Petty chancellor of the Exchequer, and Lord Ellenborough lord Chief-justice.

Parliamentary proceedings.—The first measure brought forward by the new ministry was a change in the mode of recruiting the army, the prominent part of which was, that the enlistment should continue for a limited term of years. Another alteration in the military system was to train a certain number of persons, not exceeding 200,000, out of those liable to serve in the militia; and some regulations were also made relative to the militia itself. The budget, which was opened on the 28th March, exhibited the unredeemed national debt of Great Britain and Ireland to be nearly L.556,000,000, and the redeemed debt to be L.127,000,000. The requisite supplies were stated at L.43,618,672; and among the proposed ways and means were a loan of eighteen millions, and war taxes to the amount of nineteen and a half millions. The property tax was at this time advanced from six and a half to ten per cent. The free interchange of every kind of grain between Great Britain and Ireland, without bounty or duty, was an important measure of domestic policy, which passed into a law; and the abolition of the slave trade, to the satisfaction of every friend of humanity, was finally effected during this session.

Affairs of France.—The power of Bonaparte still continued to extend itself. The territory of Naples was occupied by a French army under the command of Joseph Bonaparte, who was proclaimed king on the 30th March; and the splendid exploit of Sir John Stuart, on the plains of Maida, where he routed the French at the point of the bayonet, was only followed by an insurrection of the Calabrian peasantry, but without any other permanent change. An attempt at pacification between Britain and France, in which Lord Lauderdale was delegated to Paris, failed,—while new plans were in agitation for the aggrandisement of France, and in particular the famous confederacy of the Rhine, as it was called, of which Napoleon declared himself Protector. The battle of Jena, so fatal to Prussia, was fought on the 14th October, and gave Bonaparte the possession of the greater part of the Prussian territory. Hamburgh was entered on the 19th November; an order for the sequestration of all kinds of English produce and manufactures, and for the arrest of English merchants, was immediately issued; and for the purpose of excluding all British commerce from the continent, the most severe decrees were enacted and rigorously executed. The Batavian republic, or the seven united provinces of Holland, were formed into a monarchy, and Bonaparte's brother, Louis, was destined to receive the crown.

Naval exploits.—Admiral Duckworth engaged a French squadron off St Domingo, and captured three ships of the line. Sir John Borlase Warren fell in with admiral Linois on his return from India to France, and took the Marengo of 80 guns, and the Belle Poule of 40 guns; and Sir S. Hood captured four out of five large frigates which were destined for the West Indies with troops.

Cape of Good Hope.—The Dutch settlement of the cape of Good Hope was this year reduced under the dominion of Britain, by an armament under the command of Sir David Baird and Sir Home Popham; and this valuable colony has since continued subject to Great Britain.

Death of Mr Fox.—Mr Fox died on the 7th of September, and his death, as might be expected, was followed by some changes in the ministry; Lord Howick was his successor as secretary for foreign affairs. Parliament having been dissolved, the new parliament met on the 19th December, and the vacillating conduct of Prussia was the subject of discussion in the debates on the usual addresses.

1807.—When parliament re-assembled, a discussion took place on the late negociations for peace with France. In the financial statement laid before the house of Commons, the requisite supplies amounted to L.40,527,000 for Great Britain, and L.5,314,000 for Ireland. A motion was made in the house of Commons by Lord Howick, for leave to bring in a bill for securing to all his majesty's subjects the privilege of serving in the army or navy, upon their taking an oath prescribed by act of parliament; and for leaving to them, as far as convenience would admit, the free exercise of their respective religions. But the progress of the bill was interrupted by a change in the administration on the 25th March, and on the day following the late minister stated the principles on which they were friendly to the bill for granting relief to the catholics and other dissenters; and in this disposition, which was at variance with the sentiments of the king, the change alluded to had originated.

New Ministry.—The principal places in the new administration were occupied by the duke of Portland, as first lord of the Treasury; Mr Canning, secretary for Foreign Affairs; Lord Hawkesbury for the Home Department; Lord Castlereagh for War and colonies; Lord Eldon, Lord-chancellor; Mr Perceval, chancellor of the Exchequer; earl of Chatham, master-general of the Ordnance; earl of Westmoreland, lord Privy-seal, Earl Camden, president of the Council; and Lord Mulgrave, first lord of the Admiralty. Parliament was dissolved; and when the new parliament assembled on the 22d June, the issue of the debates on the topics which led to that measure shewed that the present administration had a decided majority in the house. The new military plan, by which the regular army was to be augmented from the militia, was introduced aud passed into a law, and some regulations with regard to the internal affairs of Ireland were found necessary, and passed into laws.

Expedition against Copenhagen.—A powerful expedition was fitted out against Copenhagen this summer, for the purpose of obtaining possession of the Danish fleet, to prevent its falling into the hands of Bonaparte. After an attempt at negociation failed, the city was bombarded, and set on fire in several places. To prevent its general destruction, an armistice was proposed, and, according to the terms of capitulation which followed, the fleet was delivered up and conveyed to England.

Among the military operations of this year, the acquisition of the island of Heligoland, which surrendered by capitulation in September, was of great importance to this country as a commercial depot, when every port in the north seas, those of Sweden excepted, was shut against British trade.

Affairs of Spain and Portugal.—Some dissentions having taken place between the king of Spain and his son, the prince of Asturias, fomented it was supposed by Bonaparte, a treaty was entered into between Spain and France, the object of which was a partition of the kingdom of Portugal, and by a secret convention French troops were to be admitted into Spain. Bonaparte demanded of the court of Portugal to shut the ports of that country against England, and, in case of refusal, threatened them with war, for which he immediately prepared. A French army entered Portugal, and on the 29th November the prince, with all the royal family, sailed from the Tagus with his fleet of eight sail of the line and four frigates, and proceeded to Rio Janeiro, accompanied by four English men-of-war. The fleet had not left the river, when a combined army of French and Spaniards appeared in sight of Lisbon.

1808.—When Parliament met in the end of January, the expedition to Denmark became the leading topic of debate in both houses; and considerable discussions also took place concerning the orders in council which had been issued subsequently to Bonaparte's decree of blockade. The annual budget was brought before the house in April, and the amount of the supplies was stated at L.43,000,000 for England, and L.5,700,000 for Ireland. The produce of the war taxes was estimated at L.20,000,000, and among the ways and means were a loan of L.8,000,000, and additional taxes to the amount of more than L.300,000; bills for establishing a local militia of 200,000 men, to be trained for 28 days annually; for the melioration of the criminal law in England, by decreasing the number of capital punishments; for the better administration of justice in Scotland, by dividing the Court of Session into two chambers; and for prohibiting the distillation of spirits from corn or grain for a limited time,—were passed into laws.

Affairs of Spain and Portugal.—The affairs of Spain began now to assume a serious aspect. The dissensions of the royal family terminated in the abdication of the king, the nomination of his son to the throne, the seizure of the whole family by Bonaparte, and while they were his prisoners at Bayonne, the renunciation of the Spanish crown in favour of his own family, and the elevation of Joseph Bonaparte to the throne. But the nation did not calmly submit to this humiliating reverse; the people, indignant at this unparallelled usurpation, rose in a mass, and sent deputies to London soliciting the aid of Britain; peace with Spain was proclaimed; the Spanish prisoners in this country were liberated and sent home; the patriots were liberally furnished with warlike stores; and a league, offensive and defensive, was concluded between Spain and Portugal. The Spanish patriots having obtained possession of Cadiz, forced a fleet of five ships of the line, with 4000 seamen, to surrender; they were successful also in other provinces; and the new king, doubtful of his security in the capital, evacuated Madrid. The British forces had landed in Portugal to support the cause of independence in that quarter; and, under Sir Arthur Wellesley, had twice defeated the French, first at Roleia, and then at Vimiera; but the command having devolved on Sir Hew Dalrymple, a convention was agreed to, by which the French, without being considered prisoners of war, were to be conveyed home at the expence of Britain, and with all their arms, equipments, and private property. The intelligence of this convention was received at home with great dissatisfaction, because the advantages of the victory at Vimiera, which might have been followed by an unconditional surrender, were entirely sacrificed. Towards the close of the year, the French having defeated the patriots, advanced upon Madrid, and soon became masters of that capital, while Sir John Moore, with a body of British troops, entered Spain for its relief; but the adverse state of affairs caused an alteration in his plans, and compelled him to the disastrous retreat which terminated in his death at Corunna, while he bravely withstood, with his exhausted army, the impetuous attack of the pursuing enemy.

Sweden.—War being declared against Sweden, by Russia, Prussia, and Denmark, a British squadron with a body of forces was dispatched to her assistance against the combined powers; but the measures of the king, dictated more by the impulse of passion than by rational policy, were incompatible with the instructions of the British commander, and thus rendered the proffered aid of no avail.

1809.—The early part of this session of parliament was much occupied with charges of corruption against the duke of York in his military capacity as commander-in-chief. After a long examination of evidence, a motion was made, and carried by a considerable majority, that personal corruption and connivance at corruption imputed to the duke are wholly without foundation, and the business terminated by a formal communication to the house, that his royal highness had resigned the command of the army. The business of East India appointments, and of the employment of influence in returning members of parliament, was also the subject of investigation, and a bill was passed to prevent bribery and corruption in procuring or obtaining seats in parliament. This year the amount of supplies for Great Britain and Ireland was stated at L 53,862,000; and, among the ways and means, were a loan of eleven millions for Great Britain, and nineteen millions of war taxes. On no former occasion was the loan contracted for on such favourable terms for the public, arising, it was supposed, from the depressed state of foreign trade.

Affairs of Portugal and Spain.—Sir Arthur Wellesley, with a reinforcement of troops, having landed at Lisbon in April, proceeded to take the command of the British army at Coimbra, and advanced against Oporto, which was abandoned by the French. The defeat of the Spaniards in Estremadura, rendered it expedient for the British commander to turn to the southward; and being joined by some Spanish troops, he proceeded along the valley of the Tagus, against the French, who were posted near Talavera; and on the 27th of July a severe action commenced, and terminated in a complete repulse of the French, but the junction of several bodies of the enemy obliged Sir Arthur Wellesley to retreat; in other parts of Spain the French were generally successful.

Germany.—A new rupture with Austria required the presence of Bonaparte in Germany; war was declared against him by the emperor Francis, and such was the rapidity of their hostile preparations, that the battles of Abensberg and Eckmuhl were fought on the 20th and 22d of the same month. Another sanguinary action took place at the village of Asperne, where the French emperor met with a very severe check. But the decisive battle of Wagram was fatal to the Austrians, and led to an armistice and peace, which was signed at Vienna the 15th of October.

Walcheren expedition.—For the purpose of gaining possession of the islands commanding the entrance of the Scheldt, and especially the port of Flushing, and to destroy the French men-of-war, dock-yards, and arsenals in that river, great preparations were made in equipping a powerful armament, and the expedition, under the command of the earl of Chatham, sailed in the end of July. Flushing, after a tremendous bombardment, surrendered; but Antwerp was too strongly fortified and defended to give any hope of success against that place; and as the islands of Walcheren and South Beveland were not the ultimate objects of attack, and great sickness prevailed among the troops, Lord Chatham, with the greatest part of his army departed for England on the 14th of September. Part of the troops was left to preserve a commercial intercourse with Holland; but the dreadful mortality from the fever continuing unabated, the island was finally evacuated on the 23d of December; and thus terminated this ill-fated and ill-planned expedition.

Among the military transactions of the present year may be enumerated, the destruction of a number of French ships near Rochelle, by a squadron under Lord Gambier and Lord Cochrane; the capture of Martinique, and the surrender of the French colony of Cayenne, and of the French settlement of Senegal on the coast of Africa; and the reduction of the Seven Islands by a British force, and the restoration of that republic.

The 25th of October of this year, which was the 50th anniversary of the king's accession to the throne, was celebrated throughout the United Kingdom as a jubilee, and was distinguished by every demonstration of marked respect for his virtues, and loyal attachment to his person.

1810.—The late events in Spain, and the unsuccessful expedition to the Scheldt, formed the chief topics of debate on the address to the king's speech on the opening of parliament. These questions which were keenly debated within doors, were the subjects of comment without, and led first to the imprisonment of J. Gale Jones in Newgate, for a violation of the privileges of the house of Commons, and, finally, the commitment of Sir Francis Burdett to the Tower, on which occasion, in consequence of the resistance offered to the execution of the warrant, a mob collected and committed many outrages, and being fired at by the military, some lives were lost, and several persons were wounded.

The supplies voted this year, were stated at L.50,566,000, for Great Britain and Ireland; and among the ways and means were a loan of eight millions, and the war taxes estimated at 19½ millions, without any new taxes.

Spain and Portugal.—Early in this year, the progress of the French arms had been so successful in Spain, that they had the command of a line of posts from the Mediterranean to the bay of Biscay. But, their great object was the possession of Portugal, in which they were opposed by the consummate address of Lord Wellington, who determined to act on the defensive, and not to risk a general engagement with a force so much superior to his own army. He therefore retreated towards Lisbon, gave Massena, the commander of the French, a severe check on the heights of Buzaco, and at last retired to the strong lines of Torres Vedras.

The cortes of Spain, composed of the national representatives, assembled at Cadiz in September, acknowledged Ferdinand VII. passed an act for a new levy of 150,000 men, and for the subsistence and equipment of the existing armies, and decreed the liberty of the press, while they resolved to publish their own proceedings in regular journals.

The principal events connected with the aggrandizement of France this year, were the marriage of the emperor with the daughter of the emperor of Germany, and the annexation of Holland to his overgrown territory.

Among the military operations, may be noticed Guadaloupe, the last island belonging to the French in the West Indies, which submitted to a British force; and in the East Indies the isles of Bourbon and France, the Dutch settlement of Amboyna, and the whole island of Banda, surrendered to the same power.

1811.—The king's illness, which had returned at the close of the year, demanded the attention of parliament in settling the regency. The discussions on this subject finally terminated in February of the present year, and the prince of Wales, under certain restrictions, entered upon the exercise of the royal prerogative, while the management of the king's household, and the care of his person were intrusted to the queen, assisted by a council. The affairs of the Irish catholics were again brought before parliament, and the failure of their petition was the occasion of numerous meetings and much discontent. The state of the bullion and currency of the kingdom led to a very long and elaborate discussion on those subjects of political economy. In the financial arrangements which were proposed in May, the amount of supplies for Great Britain and Ireland was stated at L.56,000,000; and among the ways and means were reckoned a loan of nearly twelve and a half millions, and the war taxes at twenty millions. The return of the duke of York to the office of commander in chief was also noticed in parliament, and a motion for disapproving of that measure was lost by a great majority. During this session a clause was introduced in the mutiny bill, giving a power to courts-martial of inflicting the punishment of imprisonment in the place of corporal punishment; and a bill passed into a law for an interchange of the militia of Great Britain and Ireland.

Affairs of Portugal and Spain.—At the close of last year, the two great armies of the combined forces of British and Portuguese, under Lord Wellington, and of the French under marshal Massena, were in strong posts in the vicinity of Lisbon; but the latter, aware that he could make no impression on the admirable position of his antagonist, and being at a distance from all resources for the supply of his troops, deemed it prudent to consult the safety of his army by a timely retreat; and on the night of the 5th March he quitted his strong camp at Santarem, leaving behind or destroying some of his heavy artillery. He was closely pursued by Lord Wellington; and, after much skirmishing and some sharp actions, he entered Spain, and continued his retreat. After various other military operations, the battle of Albuera was fought; and, after a very severe action, in which the British sustained great loss, the enemy was completely repulsed, and retreated. A splendid action took place in the vicinity of Cadiz, where general Graham, with a British force, routed the French with great slaughter on the heights of Barrosa. But the siege of Tarragona was the principal event of the summer campaign. On the 28th June, a practicable breach being made, the assailants rushed in and almost instantly carried the place, when a scene of undescribable horror was exhibited in every kind of outrage and barbarous cruelty committed by the French on the garrison and inhabitants. In the French general's account of these sanguinary proceedings, it is related that 4000 were killed in the city; of 10,000 or 12,000 endeavouring to escape over the walls, 1000 were sabred or drowned, and 10,000 were made prisoners. In the defence of this place, the besieged received some succours from the British fleet.

East-Indies.—Batavia, the capital of the Dutch East India settlements, with the island of Java, in which it is situated, became a splendid acquisition to the British possessions in that region. The armament which was destined for this conquest, and which was accompanied by Lord Minto, the governor-general, landed on the 5th August; and, after a strong resistance, the city and the whole island submitted to the British power.

1812.—When the parliament met in the beginning of January, the regulation of some matters relative to his majesty's household, and for defraying the expences of the Prince Regent in assuming the personal exercise of the royal authority, as well as a provision for the princesses, occupied its attention. The state of Ireland, particularly with regard to the Roman catholics, was the subject of keen debates; and a bill passed to suppress the disturbances which had continued for some time in the town and county of Nottingham, and to render the crime of frame-breaking, which was then systematically perpetrated, a capital offence.

Death of Mr Perceval.—The tragical fate of Mr Perceval, who was shot by a person of the name of Bellingham, as he entered the lobby of the house of Commons, about five in the evening of the 11th May, excited, as might be expected, great consternation in both houses; and, it was at first supposed, would produce some material change in administration. Much correspondence, and a good deal of discussion prevailed in both houses with regard to the expected change. In the end, Lord Liverpool was appointed first lord of the Treasury, Lord Sidmouth home secretary of State, and Mr Vansittart chancellor of the Exchequer.

The financial plans for the year were laid before the house in June, and the amount of supplies for Great Britain and Ireland was stated at more than L.58,000,000; and of the ways and means, the war taxes were estimated at nearly twenty and a half millions; a loan by subscribers of exchequer bills funded of more than six and a half millions; another loan of upwards of fifteen and a half millions; and a vote of credit of three millions. New taxes to the amount of nearly two millions were proposed.

Spain.—The war in Spain was attended with various success. Ciudad Rodrigo was invested by Lord Wellington, and taken by storm. Badajos shared the same fate; and his Lordship advanced upon the French army under marshal Marmont, and brought him to action at Salamanca, where the French were totally discomfited with prodigious loss. After various movements, Lord Wellington obliged King Joseph to quit the capital; and with two divisions of the army he entered Madrid in the beginning of August. After the battle of Salamanca, the French deserted the blockade of Cadiz, and left behind them a numerous artillery and a great quantity of stores. To watch the motions of the French army, Lord Wellington left Madrid on the 1st September; and, after an unsuccessful attack on a fortified post near Burgos, he retreated to the Douro; and, towards the close of the year, established his head-quarters on the Portuguese frontier.

Russia.—The north of Europe beheld one of the most numerous and powerful armies collected from all the territories under the dominion and influence of Bonaparte, and destined to force the submission of Russia to his boundless ambition, by the actual possession of its ancient capital. The plan of defence adopted by the Russians was, to retreat gradually before their invaders, and to make resistance only in favourable positions, where it might be effectual. The first vigorous opposition was made at the city of Smolensko; but the most sanguinary conflict took place near the village of Moskwa, where the Russian main army, having taken a strong position, were attacked on the 7th September; and the whole army, on each side, of 120 or 130,000 men, was engaged from morning to night. Each party claimed the victory; but the French entered Moscow on the 14th of the month, and were disappointed in the extreme at the destruction of part of the city by fire. The want of all supplies, from which they were cut off by the active vigilance of the Russians, rendered it a very insecure place for winter-quarters; and on the 19th October, the French emperor quitted Moscow, and when a Russian winter had set in, with deep snow, commenced one of the most disastrous retreats recorded in history. It ended in the total destruction of this mighty army. According to the Russian accounts, the losses of the French by capture up to the 26th December, were, 41 generals, 1298 officers, 167,000 non-commissioned and privates, and 1121 pieces of cannon.

America.—The differences with America broke out this year into open warfare; and as the American government had obviously in view the conquest of Canada, hostilities commenced in that quarter; and the American general, who had entered the province of Upper Canada, after various movements, surrendered to an inferior British force; and in another attack, another American general, with 900 men, surrendered himself prisoner on the field.

1813.—The attention of parliament, on its meeting after the recess, was occupied with discussions on the war with America; the claims of the Roman catholics; the affairs of India; and the financial arrangements, in which the requisite supplies of the year were stated at a sum exceeding L.72,000,000 for Great Britain and Ireland; and of the ways and means were, war taxes L.21,000,000, a loan of L.21,000,000, and a vote of credit for L.26,000,000.

Affairs of Spain.—Lord Wellington having received reinforcements from England, moved from his quarters in May, marched to Salamanca, and pursued the French, who retreated before him till they reached Vittoria, where they took up a strong position. A vigorous attack was made by the combined army, which terminated in the total discomfiture of the French, under the command of king Joseph and marshal Jourdan, and with the loss of their artillery and baggage. After various successes, and after the fall of the strong castle of St Sebastian, Lord Wellington pushed forward; and, towards the close of the year, obtained a firm footing on the French territory.

Affairs of France.—The advance of the Russian army, under the command of the emperor, on the confederated territories attached to France, and the defection of Prussia from his interests, roused Bonaparte to make a powerful effort to recover his lost ground. By a decree of the senate, 350,000 men were placed at his disposal. With a formidable force he proceeded to the north, and engaged the combined Prussian and Russian army in a general action near Lutzen, the result of which was, that the allies kept the field, and the French retreated. Bonaparte afterwards advanced to the Elbe, and his troops occupied Dresden, Leipsic, and Breslau. The accession of Sweden to the league against the French emperor, by which he engaged, in consequence of a subsidy from Britain, to furnish 30,000 men on the continent, threw something in the balance in favour of the allies. Napoleon, foreseeing the difficulties which were rising around him, proposed an armistice, which was agreed to; but was at length broken up by the Austrian minister delivering to the French minister a declaration of war on the part of his court against France, when hostilities were resumed. The allies attacked Dresden, which was strongly fortified, and defended by Bonaparte with a force estimated at 130,000 men. A severe action took place, at the conclusion of which the allies retired. After various movements and successes on the part of the allies, the French retreated towards the Elbe, and the city of Leipsic became the great scene of contest between the contending armies. At this time the accession of 55,000 Bavarian troops strengthened the allies. The engagement commenced on the 16th October; on the 17th preparations were made for greater efforts; and after a dreadful conflict on the 18th, in which the French had lost 40,000 men, in killed, wounded, and prisoners, the town was carried on the succeeding day, after a short resistance, and the allied sovereigns entered it two hours after Bonaparte had made his escape. The French army retreated in great disorder; the allies continued the pursuit, and, excepting those of the French who were left in the garrisons, liberated the whole of Germany from the troops of the invader.

Holland also shared the benefits of this revolution. The approach of the allied troops to Amsterdam encouraged the people of that city to throw off the yoke of France, and to proclaim the sovereignty of the house of Orange. A deputation was sent to London to invite the prince to resume his authority; and, with the aid of England, he made his entry into Amsterdam on the 1st of December. The allies continued to advance on various points of the French frontier; and Bonaparte, seeing the country in a state of invasion, had recourse to extraordinary measures to secure the means of its defence.

America.—The Americans still directed their enterprises to Canada, and various actions took place in the course of the summer, between the naval armaments on the lakes, or the land forces on their shores. Offensive warfare was also carried on against other parts of the American territory, and particularly on the rivers at the head of Chesapeake bay, at Hampton in Virginia, and on the coast of North Carolina.

1814.—The peculiar situation of France, at the commencement of this year, arrested the attention of all Europe. The allied armies had crossed the Rhine, and were advancing to the interior; and, after various actions, some of which were strongly contested, continued their progress. Negociations for peace were entered into at Chatillon, where the plenipotentiaries of the different powers met; but they terminated unsuccessfully, and the allies proceeded to the vicinity of Paris, which was defended by the French army under Joseph Bonaparte. Their position on the heights near Paris was carried, after an obstinate resistance. A cessation of hostilities took place, and Paris being evacuated, the allied sovereigns entered it on the seventh day. A provisional government was established; Bonaparte was deposed, and had the isle of Elba, in the Mediterranean, in full sovereignty, assigned to him for life. In the meantime Lord Wellington was advancing into France; a part of his army had entered Bourdeaux in March; and that city declared for the Bourbons. The British general proceeded to Toulouse, in pursuit of marshal Soult, and a smart action took place on the 10th of April, after which the town was evacuated by the French army. The intelligence of the transactions of Paris also produced a suspension of hostilities in this quarter.

While Bonaparte was proceeding to take possession of his small territory, the head of the Bourbon family emerged from his retirement in England, was hailed as a sovereign, and made a public entry into London. On 24th April he embarked at Dover, was welcomed at Calais with every mark of loyalty and affection, and on the 3d May made a solemn entrance into Paris. The treaty of peace between the allies was signed at Paris on the 30th of May. By this treaty the boundaries of France were to be such as they were in 1792, and all the colonies, factories, and settlements which she possessed at that period to be restored, with the exception of Tobago, St Lucia, and the isle of France. Malta and its dependencies are to belong to Great Britain, and the latter power resigned all conquests from the Dutch, exclusive of the Cape of Good Hope, Demerara, Essequibo, and Berbice. The electorate of Hanover, with certain annexations, acquired the title of a kingdom, under his Britannic majesty.

The subject of the corn laws was discussed in parliament towards the close of the session; the budget of the year was laid before the house in June, and the amount of supplies exceeded L.75,600,000; and among the ways and means were two loans of forty millions and a half, and a vote of credit for three millions; and a bill was passed for suppressing outrages in Ireland.

America.—The warlike operations on the frontiers of Canada were conducted with great vigour, and with various success. Many smart actions took place between the naval forces of the different powers on the lakes, as well as some severe contests with the troops on shore. An attempt was made with a strong force to penetrate into the state of New York, but it failed. The attack on the city of Washington, the new capital of the United States, was more successful. The arsenal, dock-yard, treasury, senate-house, and other public buildings were committed to the flames. Private property was respected, and strict discipline was kept up among the troops; but still the destruction effected in this expedition was much regretted by many. The town of Baltimore was the next object of attack by the same force; but the number and strong posi-

Civil history.

tion of the Americans who defended it, rendered the attempt impracticable. It was, therefore, abandoned, with the loss of general Ross, the commander of the troops, who fell in the advance. Negociations for peace with America, which had for some time been going on between the commissioners of the two powers, who met first at Gottenburgh and then at Ghent, were finally concluded on the 24th December, when a treaty of peace was signed between Great Britain and the United States.

1815.—The consideration of the corn laws was resumed in parliament this year, and, after long discussions, the price of wheat, which regulated other kinds of grain, at which free importation was permitted, and below which it was prohibited, was fixed at 80s. per quarter. A bill for the introduction of trial by jury in civil causes in Scotland passed into a law, but it was left optional with the judges of the court of Session in what cases such trials should be granted. In consequence of the great events which were then in agitation, the supplies required from Great Britain amounted nearly to the enormous sum of 80 millions, exclusive of nine millions and three quarters for Ireland, and a vote of credit of six millions.

America.—At the very time that the preliminaries of peace were agreed to and signed between Great Britain and the United States, some active military operations were going forward in a distant quarter of the American territory. In the last week of the preceding year and the commencement of the present, a meditated attack on New Orleans was put in execution. In the advance to a strong position occupied by the Americans, general Pakenham, the commander, was killed; the two generals next in command were wounded, and one of them mortally; the troops were disheartened and fell back in disorder, and the enterprise, which now seemed hopeless, was abandoned with great loss to the assailants. But the army afterwards re-embarked with all their stores. Fort Mobille capitulated to a British force in the beginning of February; and this was the concluding action of the war.

East Indies.—In the close of last year, disputes between the British government and Bengal and the Nepaulese at last broke out into open hostilities; and after some active warfare, which was followed with various success, the whole tract of border-land, which was the subject of difference, was annexed to the territory of the East India company. The whole of the island of Ceylon fell under British authority this year. The conduct of the king of Candy had become extremely oppressive to his own subjects, and with the assistance of the British troops, who advanced into the interior, they threw off his yoke, seized his person, declared his right violated, and placed themselves under the protection of the government of Great Britain. This revolution, it can scarcely be doubted, will prove favourable to the liberties of the natives.

Affairs of France.—The scenes of deepest interest which occupied the attention of Europe, were exhibited in France in the course of this year. After some previous preparations, which passed without suspicion, the ex-emperor of France departed from Elba, on the evening of the 26th February, with about 1000 troops, embarked in five vessels. He landed in France on the 1st March, and having proceeded to Lyons without opposition, he entered that city, and was hailed as emperor by the soldiers and the populace. Marshal Ney, who had made a voluntary offer of his services to the king to oppose the invader, joined him with his whole division; and the king despairing of support from the army, left Paris on the 19th. It was entered by Bonaparte on the next day, without the slightest opposition in his progress. The commissioners of the allied powers, then at Vienna, issued a declaration, in which they bound themselves to maintain the conditions of the treaty of Paris, and not to relax their exertions, till the usurper should be deprived of the means of renewing his attempt on France. In the end of last year, the whole fortified frontiers of the Belgic provinces, on the side of France, was occupied by strong garrisons, either of British troops or of those in the interest of Britain; and from the commencement of the alarm of the invasion, reinforcements had been dispatched from this country, and the chief command was committed to the duke of Wellington. The Prussian army, commanded by prince Blucher, arrived in the end of May, and the plan of co-operation was arranged between the two generals.

Bonaparte left Paris on the 12th June, and having placed himself at the head of a numerous and well appointed army, animated with enthusiasm, and full of confidence in their leader, he assailed the Prussian posts on the 15th; the Prussians were again attacked next day, and, after a severe conflict, were forced to retire before such superior numbers. Lord Wellington, in the mean time, advanced with his whole army upon Quatre Bras, with the intention of supporting the Prussian general; but he was himself attacked by a large body of cavalry and infantry, with a powerful artillery; and although the repeated charges of the French were steadily repulsed, a considerable loss was sustained on the part of the allies. The combined armies retired in the night, and on the morning of the 17th, retired to Waterloo. On the morning of the 18th, Bonaparte collected his whole force on the heights opposite to the British army; and, at 10 o'clock, the action commenced. A heavy cannonade was kept up against the whole British line, and repeated charges of infantry and cavalry were made in the course of the day, all of which, excepting in one case, were uniformly repulsed. Late in the evening, a desperate onset against the left of the British centre took place, and a severe contest followed. But the Prussians who had been attacked by another division of the French army, fell on the flank of the enemy, who began to retreat, and the duke of Wellington seizing this opportunity, advanced with his whole line of infantry, supported by the cavalry and artillery. The French, unable to withstand this vigorous movement, fled with the utmost precipitation, and left on the field about 150 pieces of cannon, with their ammunition. On no former occasion were the valour of British troops, and the talents of their noble commander, more conspicuous. The loss sustained on the part of the British, in so sanguinary a conflict, was unusually severe. Of killed, wounded, and missing, of the British and Hanoverians, the number exceeded 12,000; two generals, and four colonels fell on the field; and nine generals and five colonels were among the wounded.

Bonaparte seeing his fate decided, hastened back to Paris; and after some ineffectual measures to recover his power, was forced to declare that his political life was terminated. On the 3d July he arrived at Rochefort, and seeing no prospect of escape, went on board a British ship of war, and was in a short time, by the determination of the confederate sovereigns, conveyed to St Helena, which was destined to be the place of his future residence. The allied armies pushed forward to Paris, and, after some resistance, took possession of the city, in terms of a convention with the chambers, in whom the temporary authority was placed. But in a short time Louis XVIII. returned to the capital, and was restored to the throne; and to preserve the tranquillity of France, and it may be added, of Europe, a considerable body of troops, in the pay of France, belonging to the allied powers, was to retain the occupation of strong holds on its frontiers for a limited period.

BRITAIN, NEW, an extensive district of North America, having Hudson's bay and strait on the north and west, Canada and the river St Laurence on the south, and the Atlantic ocean on the east. It is also called Labrador.—See LABRADOR.

BRITAIN, NEW, a large island at the eastern extremity of Papua, or New Guinea, in the Southern Pacific ocean. This island presents a mountainous appearance, and is well wooded; the vallies are fertile, producing cocoa-nuts, yams, and ginger; it is well watered with numerous streams, and very populous. The inhabitants appeared to be hardy, well made, and of a dark copper colour.

BRITANY, a province of France before the revolution.—See BRETAGNE.

BRIXEN, the capital of a district of the same name in the Tyrol, stands on the banks of the river Eisach, and is surrounded with mountains, which are clothed with vineyards. The houses are well built; some of the public buildings are respectable structures, and several squares are spacious and commodious. The mineral waters in the vicinity attract a good deal of company; and a red wine, which is produced in the surrounding territory, furnishes the chief commodity for the trade of the place.

BRIZA, QUAKING-GRASS, a genus of plants belonging to the class Triandria, and of which several species are natives of Britain.

BROACH, or BROTCHE, from a French word, which signifies an awl, or bodkin, is employed in Scotland to denote an instrument corresponding with the *fibula*, or clasp of the Romans, for the purpose of fastening the vest, or upper-garment. The broach is usually made of silver, sometimes of a roundish form, and sometimes heart-shaped; and it is furnished with a tongue, crossing its diameter, or with two tongues, one on each side of a cross-bar in the middle, to fasten the folds of the garment. Some broaches are of elegant workmanship, and richly ornamented, are carefully preserved in families, and in former times particular virtues were ascribed to them, so that they seem to have been employed as amulets.

BROACH, a district of the province of Guzerat, lying on the west coast of India, between the 21° and 23° of N. latitude, and having the gulf of Cambay for its western boundary. This territory, which is one of the most populous and best cultivated on that coast, was acquired by the British in 1803. In many places the soil is extremely fertile, and produces abundance of rice and cotton. Numerous villages are scattered over the province, and, before it came under the dominion of the British, robberies and murder, from being passed over with impunity, or visited only by slight fines, were very frequent. But it is gratifying to find that the security of life and property is now greatly improved, by the more rigorous and equal administration of the laws. Superstitious devotion is a striking feature in the character of the Hindoos of this province. When far advanced in years, or absorbed in spiritual contemplation, those who have acquired the reputation of great sanctity not unfrequently submit to be smothered alive, in a pit dug by themselves or their disciples. This was the fate of Kubeer, a famous saint, from whose toothpick, according to the tradition of the country, sprung the celebrated banyan tree, which grows in an island in the Nerbudda, and is justly reckoned the most extraordinary vegetable production in existence.—For an account of this tree see *Ficus*, under BOTANY.

BROACH, the capital of the district of the same name, in the province of Guzerat, in the East Indies; stands on the north bank of the Nerbudda, about 25 miles from its junction with the sea. The manufacture of cotton stuffs is extensive, and the waters of the Nerbudda have been long celebrated for their peculiar property of communicating a pure white to the cloth. The price of labour is extremely low; the wages of a man is about 4d. a day, of a woman about 3d. and of boys and girls from one halfpenny to 2d. and even these rates are nearly double those of the manufacturing districts in Bengal. The population of the town and of the district immediately attached to it, exceeded 80,000 before 1791, when a great famine carried off more than 25,000.

An hospital for animals is supported at this place by the donations of the Hindoo inhabitants, and every marriage and mercantile transaction is taxed for the expence of the establishment, and in this way an annual revenue of L.1000 Sterling is acquired, the greater part of which goes to enrich the managers. No other animals beside milk cows are admitted of late years to this asylum, and the profit which they yield is equal to the expence of their support. Broach is 221 miles from Bombay, and 287 miles from Poonah.

BROCADE, or BROCADO, in its more limited meaning, was employed to signify a stuff or cloth composed entirely of gold or of silver, or of a mixture of both; but in a more enlarged sense, it is applied to a stuff of gold, silver, or silk, raised and enriched with flowers, foliage, and other ornaments, according to the fancy of the manufacturer. See Cloth Manufacture.

BROEK, a large village of North Holland, which is remarkable for the cleanness and neatness of the houses and streets. The houses are built of wood, and roofed with tiles, and the streets, into which neither carriages nor cattle are admitted, are paved with bricks well polished, and strewed with sand. The outside of the houses is painted with brilliant colours, and the gardens, in which no weed is ever allowed to appear, are furnished with the choicest flowers, and adorned with beautiful shell-work. The commercial intercourse of Broek with the Baltic and some of the mercantile cities in the north of Europe was formerly considerable; but the trade now is chiefly confined to corn and cattle. Merchants who have retired from business, or who are connected with mercantile concerns in Amsterdam, are the principal inhabitants.

BROKER, a person who is employed to manage affairs, or to conclude bargains relative to money and mercantile transactions. Brokers have been distinguished by different denominations, according to the nature of the business which they manage, as Exchange-brokers, Insurance-brokers, Stock-brokers, and Pawn-brokers.

Exchange-brokers are agents who transact the business of exchange between the merchants of different countries. Those who exercise this business in London are required by law to have a licence from the lord mayor and aldermen, and to give bond for the faithful performance of their office; and if any person act as a broker without being thus licensed and admitted, he is subject to a penalty of L.500, and those who employ any such persons forfeit L.50.

Insurance-brokers are employed in transacting the business of insurance between the merchant or party insured, and the insurers or underwriters. The nature of the transactions in which agents of this kind are engaged, requires that they should be persons of honour and respectability, in whom great confidence may be placed. By the ordinary practice of trade in London, the underwriters give credit only to the broker for their premiums, and can have recourse on him only for payment, while he alone, and not the underwriters, can recover the premiums from the insured. But the duties and obligations of Insurance-brokers may be seen at large in Marshall's *Treatise on Insurance*.

Stock-brokers are agents employed to buy and sell shares in the joint stock of a company or corporation, and also in the public funds. The transactions relative to the purchase and sale of stock in the public funds, usually come under the denomination of *stock-jobbing*. As the practice of stock-jobbing has been often carried to such an excess as to become not only highly injurious to private individuals, but even in some degree to affect public credit, it has been placed under strict regulations by legislative enactments. Among other things, it is enacted, that contracts in the nature of wagers incur a penalty of L.500; and by the sale of stock of which the agent is not possessed, a forfeit of L.100; and that brokers keep a book, in which all contracts, with their dates, and the names of the parties concerned, shall be recorded, under a penalty of L.50.

Pawn-brokers, or *pawn-takers*, are persons who lend money upon pledges, and usually at a high rate of interest. As the embarrassed affairs of persons who pledge goods are apt to expose them to imposition and fraud, the business of pawn-broking is strictly regulated by the legislature. Pawn-brokers are required to take out an annual licence, on a L.10 stamp, within the bills of mortality of London, and on a L.5 stamp in any other part of the kingdom, for each shop kept, under a penalty of L.50 Sterling.

According to various enactments, the following are the rates of profit allowed to brokers for interest and ware-house room. For every pledge, on which there has not been lent above 2s. 6d. one halfpenny per month; for 5s. one penny; for 7s. 6d. one penny halfpenny; for 10s. twopence, and so on progressively in the same proportion for any sum not exceeding 40s.; and for any sum exceeding 40s. and not exceeding L.10, at the rate of threepence for every 20s. Pawned goods may be redeemed within seven days after the expiration of any month without paying interest for the seven days; but after seven, and within sixteen days, interest for one month and a half is due. After the first fourteen days, the pawn-broker is entitled to interest for the whole month.

By other regulations, the pawn-broker is required to make entries and to give duplicates. If he refuse to deliver up goods pledged within one year, on tender of the money with the interest due, a justice of peace is authorised to commit him till satisfaction be obtained. After the expiration of a year, pawned goods may be sold by public auction; but they must be exposed to public view, catalogues must be published, and two advertisements of sale must be inserted in some newspaper, at least two days before the first day's sale; and in case of failure, the pawn-broker subjects himself to a forfeit of L.5 to the owner. Pawn-brokers receiving notice from the owners of goods before the expiration of a year, are not allowed to dispose of the goods until three months from the termination of that year. They are required to enter in their books an account of sales of all goods pawned for more than ten shillings; and in case of sale, the overplus must be paid to the owner, if demanded, within three years, interest and costs being deducted, under a penalty of three times the amount of the sum lent. Pawn-brokers are prohibited from purchasing goods in their custody, or suffering them to be redeemed with that view; from lending money to persons appearing to be intoxicated, or under 12 years of age; from purchasing duplicates of other pawn-brokers, and from buying goods before eight in the morning and after seven in the afternoon. Besides various other regulations specified in the enactments on the subject, and in those cases where no penalty is provided, pawn-brokers shall forfeit L.5 for every transgression of the law.

BROMELIA, the Pine-apple, a genus of plants belonging to the class Hexandria. See Botany; and for the mode of cultivating this delicious fruit, see Gardening.

BROMLEY, a market-town of Kent, in England, situated on the banks of the river Revensbourne, contains about 3000 inhabitants, and is chiefly remarkable for a charitable establishment founded by Dr Warner, bishop of Rochester, in the time of Charles II. and destined for the support of twenty females, the widows of poor clergymen. A bequest of L.10,000, by Mrs Betenson of Bradbourne, and another, still more liberal, of L.12,000 by Mr Pearce, names which are well entitled to be transmitted to posterity, have greatly enriched this excellent institution. A spring in the vicinity of Bromley, affords a mineral water, whose properties are similar to that of the celebrated Tunbridge-wells.

BROMSGROVE, a market-town of Worcestershire in England, stands on the river Salwarp, and is 12 miles distant from Worcester, and 116 miles from London. An elegant church, on an elevated spot, with an approach by a flight of fifty steps, furnished with windows of painted glass, and containing some fine monuments of eminent characters, is the chief ornament of the place. The number of inhabitants is about 6000, and they are chiefly employed in the manufacture of woollen and linen cloth, and various kinds of hardware.

BROMUS, Brome-grass, a genus of plants belonging to the Triandria class, and including twelve species, which are natives of Britain, one of which, *Bromus Sterilis*, or Barren Bromegrass, is very common in fields, hedges, and waste places.

BRONCHOCELE, a peculiar tumour which is produced on the anterior part of the neck, and to which some of the inhabitants of the districts round the foot of the Alps of Switzerland, and some other countries, are much subject.

BRONZE, a metallic alloy, composed generally of copper and tin, but sometimes zinc, lead, or silver is added to communicate the sonorous property required for some of the uses to which this compound metal is applied. Bronze has been much employed for casting statues, both in ancient and modern times; and for this purpose it is peculiarly proper from its durable quality.

BRONZING, is the art of communicating to figures of plaster, wood, or ivory, the appearance of real bronze figures. Two kinds of bronze, the yellow or golden, and the red, are employed for this purpose. The golden bronze is prepared of the finest and brightest copper dust; and when a red bronze is required, a small portion of red ochre, reduced to a fine powder, is added. Both kinds of bronze are applied with varnish, and to prevent the surface of the work from assuming a greenish colour, it is dried over a chafing-dish as soon as the process is finished.

The following process of bronzing is easily practised: The figure is first covered with a coat of gum-water, to which a little minium has been added; a small portion of fish glue is then dissolved in spirits of wine, by digesting them in a warm place, and the mixture is coloured with a little saffron; the filings or dust of the metal which is desired to be imitated, is mixed with the glue and applied to the figure, by means of a hair pencil.

The following method of bronzing copper is practised by the Chinese. To clean and polish the surface, it is well rubbed with vinegar and ashes, and it is afterwards well dried in the sun. Two parts of verdigris, two parts of cinnabar, five parts of sal ammoniac, two parts of the bile and liver of ducks, and five parts of alum are pounded, well mixed, and formed into a paste. The copper being heated, is covered with a coating of this paste; and after being dried, cooled, and washed, the same operation is repeated, till a covering of sufficient thickness is obtained.

BROOKE, Henry, a dramatic poet and novel writer of considerable reputation, was a native of Ireland, and was born about the year 1706. Having completed the earlier part of his education under the tuition of the celebrated Dr Sheridan, he became student of Trinity college, Dublin; and with the view of qualifying himself for the profession of the law, he resided sometime in the Temple. He married his cousin on his return to Ireland, and lived for some time in retirement; but the increase of his family, and of his expenditure, required an addition to his income; and for this purpose he had recourse to the exertion of his literary talents. About the year 1735, he visited London, and published his *Universal Beauty*, a philosophical poem; and having failed, from want of industry or inclination, in an attempt to establish himself in the practice of the law in his native country, he returned to the same metropolis, and produced the tragedy of *Gustavus Vasa*, which, from the peculiarity of its sentiments, excited great attention among the different political antagonists of the day, was applauded by one party and condemned by another, and its public representation at the theatres was prohibited by government. But the author was fully compensated by publishing the play by subscription, which was encouraged and promoted by the friends and adherents of the prince of Wales. He produced, in 1745, another tragedy, the *Earl of Westmoreland*, which was acted at the Dublin theatre; and four years afterwards, the *Earl of Essex*, which was represented at the same theatre, and at Drury-lane in 1760. In 1762, he published the *Trial of the Roman Catholics*; in 1766, the *Fool of Quality*, a novel, which attracted much notice, and continued long a favourite with the public; and, in 1774, *Juliet Granville*, a work of the same description. Mr Brooke also contributed three pieces to "Moore's Fables for the Female Sex," of which the *Female Seducers* has been much admired.

The pecuniary affairs of Mr Brooke, which seem to have been always embarrassed, obliged him, during the latter period of his life, to unite his family with that of his brother, but they lived together in great harmony. His mind had been long tinctured with religious melancholy, and this depression of spirits, with the loss of his wife after a union of nearly fifty years, and the death of a favourite child, actually induced mental derangement. Having reached the venerable age of 77, he was relieved by death from all his worldly cares in October 1783.

BROOME, William, an English poet, was a native of Cheshire, and descended of parents in a humble rank of life. He was educated on the foundation at Eton; and, by the contribution of his friends, was sent to St John's college, Cambridge, where he obtained a small exhibition; and he resided for some time in the same chamber with Mr Ford, who described him to Dr Johnson as a contracted scholar, and a mere versifier, unacquainted with life, and unskilful in conversation; and hence he was familiarly called by his companions, *the poet*. Mr Broome was early known as a translator of Homer into prose, in conjunction with Ozell and Oldisworth. A visit of Pope to a friend in the vicinity of Cambridge, afforded him an opportunity of being introduced to that poet, who employed him in making extracts from Eustathius, for the notes to the translation of the Iliad; and in the volumes of poetry called "Pope's Miscellanies," many of Broome's early productions are inserted.

When Pope was engaged to undertake a version of the Odyssey, he assigned part of the labour to Fenton and Broome; and the translation of the second, sixth, eighth, eleventh, twelfth, sixteenth, eighteenth, and twenty-third books, with notes to the whole poem, was contributed by the latter. The scanty remuneration which Broome received, amounting only to L.600, while half the sum was paid to his coadjutor, Fenton, for four books, produced a coldness and open hostility with Pope. Broome charged Pope with his avarice; and Pope, in revenge, introduced Broome into the Dunciad. Broome afterwards published a Miscellany of Poems; and, towards the close of life, he amused himself with translating the odes of Anacreon, which appeared in the Gentleman's Magazine under the name of *Chester*. He obtained several livings in the church, but never rose to a higher dignity than that of rector. He died at Bath in 1745. "Though it cannot be said of him," Dr Johnson remarks, "that he was a great poet, it would be unjust to deny that he was an excellent versifier: his lines are smooth and sonorous, and his diction is select and elegant."

BROSELEY, a market town of Shropshire in England, situated on the river Severn, and 146 miles from London. The population is about 5000; and the inhabitants are occupied in extensive iron-works in that neighbourhood, in the manufacture of glazed tobacco-pipes, and in mining, and the coal-trade. Broseley is remarkable for a burning spring in the vicinity, discovered in June 1711 by a singular noise in the night, which awoke and drew a number of people to the spot, who observed a shaking of the earth, and the water boiling up through the grass. The spring being dug round, the water sprung to a great height, and taking fire from a candle which a person held in his hand, great curiosity was excited. To secure the spring, an iron cistern was placed upon it, having a small hole in the centre. A candle being put to the hole, the water took fire, and was most violently agitated. It would sometimes burn for forty-eight hours without intermission; and so great was the heat, that a tea-kettle full of water being placed on the hole, would boil in nine minutes. It entirely disappeared in 1755, by the sinking of a coal-pit. It seems probable that the inflammable air, rising through the water, and taking fire when a burning body was brought in contact, was the cause of the remarkable effects of this spring.

BROSSES, Charles, De, a learned French author, best known by the appellation of President de Brosses, from his official situation in the parliament of Burgundy, was born at Dijon in 1709, and was early distinguished by his literary and scientific pursuits, to which, in the midst of professional avocations, his attachment continued through life. A visit to Italy, in 1739, afforded him an opportunity of examining the subterraneous city of Herculaneum, the first account of which he published on his return to France in 1750. His most celebrated work, *The History of Voyages to the South Seas*, which was undertaken, it is said, at the suggestion of Buffon, appeared in 1756, in two volumes 4to. In this work, the southern portion of the globe is distributed under two great divisions, Australasia and Polynesia, an arrangement which some succeding geographers have adopted. He was the author of a treatise on the mechanical formation of languages; and he devoted a great part of his life to a translation of Sallust, in which he endeavours to supply the chasms in the work of the Roman historian. This elaborate work was published in 1777, in eight volumes 4to. On the subjects of Grammar and Music, de Brosses was a contributor to the French *Encyclopedié*, and he furnished various memoirs to the transactions of learned academies of which he was a member. He died in 1777.

BROUSSONET, P. M. Auguste, an eminent French naturalist, was born at Montpellier in 1761, and was originally destined for the medical profession, to which the course of his studies was directed. He had the good fortune to be nominated to the chair of botany in the university, at the early age of 18, and to that branch of natural history he assiduously devoted himself. Strongly impressed with the advantages of the Linnæan classification, he employed his most zealous exertions in subduing the opposition which it experienced, and in attempting to establish it in France. In the prosecution of his favourite study, and to extend his knowledge of other departments of natural history, he visited Paris and London, and spent much of his time in examining the splendid collections which have been made for its elucidation. During his visit to the latter capital in 1782, he published his celebrated work on fishes, in which most of the rare species are described and figured.

Broussonet was early involved in the troubles of the French revolution. He became a member of the electoral college of Paris in 1789, an official situation, which required him to perform the duty of a public magistrate, in the exercise of which he was obliged to witness the most horrible outrages, to see his friends murdered, and his own life exposed to the most imminent danger; he was appointed, in 1791, a member of the legislative assembly; but, wearied with the tumults and barbarities of the times, he retired to his native city; fled from the danger which still pursued him to Madrid and Lisbon, and was at last compelled to accept of the office of physician to an embassy from the United States of America to the emperor of Morocco. Having obtained permission from the French directory to revisit France, he repaired to Teneriffe, where he spent two years in the rank of consul; and, when he returned to his native country

Brown.

in 1796, he was recalled to his professorship at Montpellier. He died in 1807. Beside the work on Fishes, he wrote a treatise on Respiration, and some others on subjects of rural affairs.

BROWN, Dr John, a clergyman of the church of England, and a multifarious writer, was born at Rothbury in Northumberland in 1715. His father, a native of Scotland, was the curate of the place, and was afterwards removed to Wigton in Cumberland, where the son received the early part of his education. He entered as a student in St John's college, Cambridge, took the degree of bachelor of arts, and returning to his native county was admitted to the clerical profession, and appointed canon and lecturer in the cathedral church of Carlisle. During the rebellion in 1745, he distinguished himself by his intrepidity in the defence of Carlisle. Excepting as a preacher, Dr Brown first appeared before the public as a poet, in two productions, the one entitled *Honour*, and the other *An Essay on Satire*, neither of which is now much known or read; but his Essays on the Characteristics of Shaftsbury, seem to have brought him greater reputation. In 1755 he became known as a dramatic writer in the tragedies of *Barbarossa* and *Athelstan*, the first of which obtained a large share of popularity; and in 1757 he published his *Estimate of the Manners and Principles of the Times*, a political work, to which Voltaire ascribes great influence in rousing the languid exertions of the nation. Dr Brown wrote also on other political subjects, on Poetry and Music, on Female Education in a sermon, a Letter to the Author of the Divine Legation of Moses, and Dialogues of the Dead.

The closing scene of Brown's life presents a melancholy picture of the connexion which too often exists between powerful genius and an ill regulated mind. In 1765 he had corresponded with a friend in Russia on the subject of establishing schools in that country, and had accepted an invitation from the empress to take an active share in conducting them. Preparations were made for his journey, and money was transmitted to defray the expences; but a severe indisposition intervened, and at last, through the advice of his friends, he relinquished the undertaking. The failure made a deep impression on a sanguine mind, and led at last to the commission of suicide; a horrid purpose, which, it is said, he had often meditated, and had even warned his friends of the dreadful apprehensions which haunted his soul. The fatal deed was executed in 1766, when he had reached the 51st year of his age.

BROWN, John, a physician, and founder of a theory of medicine which bears his name, was a native of Berwickshire in Scotland, and was born about the year 1736. Descended of parents in a humble rank of life, he was destined, when very young, to a mechanical profession, the drudgery of which he either disliked, or the talents which he discovered shewed that he was capable of rising to a more conspicuous rank; and in the grammar-school of Dunse, where he was placed, he soon gave the most satisfactory proofs, by his ardour and success in study, of his capacity for literary pursuits. His parents, who were of that class of dissenters called seceders in Scotland, encouraged by his rapid progress in the Latin language, proposed that he should be educated for the clerical profession among their own sect. But as young Brown was little disposed to adhere rigidly to their peculiar tenets and practices, he seems to have disavowed his connection with that sect as early as his 13th year, and to have become a member of the established church. Having been employed for some time, either as a private tutor in a gentleman's family in the country, or as an assistant in the grammar-school of Dunse, he went to Edinburgh in his 20th year, and having completed the requisite course of study in the classes of philosophy in the university, he entered himself as a student of divinity; and it is highly creditable to young Brown, that during the time of his studies at Edinburgh, his talents and industry enabled him, by private teaching, to support himself. After a short retirement in the country, he returned to Edinburgh in the year 1759, when he commenced the study of physic, and finally renounced that of divinity.

While he prosecuted his medical studies, he was still indebted for support to his literary attainments. He was much employed in giving private instructions to students, in colloquial exercises in the Latin language, which are necessary for those who are examined for medical degrees in the university, and in translating inaugural dissertations into the same language. By these labours he recommended himself to Dr Cullen, who not only warmly patronised, but received him as a private tutor in his own family. The conversation of that eminent man and celebrated professor, and the friendly and familiar terms on which he lived with him, as well as the permission which he obtained of delivering private lectures, or illustrations of the doctor's public lectures, to a number of pupils, could not fail to be highly beneficial to the progress of Mr Brown's medical studies. With these flattering prospects he married the daughter of a respectable tradesman in Edinburgh, and opened a house for receiving students as boarders. Having the hope of deriving great benefit from his instructions and conversation, many pupils in a short time crowded his apartments. But want of economy, or mismanagement, produced a serious embarrassment in his affairs; and the disappointment of obtaining a medical professorship in the university, which he ascribed to the interference of Dr Cullen, soured his mind, and led to an open rupture with his patron and friend.

From this quarrel, in which it has never been stated what share of blame was due to Dr Cullen, the celebrated theory of Brown, it is said, derived its origin; but it is surely little creditable to the reputation of the theorist, that the new doctrines arose from irritated feelings, rather than from a desire to investigate the truth. The opinions of Brown were received and supported with enthusiasm by one party, while they were condemned and rejected by another. In the collision of sentiments and opinions on the disputed subjects, all the rage of religious controversy frequently appeared, and, to complete the resemblance, even some degree of persecution was not wanting. All this tended to unite more closely those who took the same side; and it was peculiarly unfortunate for the author of the new theory, that his convivial habits led him to form clubs and societies, which met in taverns for very different purposes from matters of mere speculation. The institution of a masonic association, in which the conversation was conducted in the Latin language, with the view of gaining proselytes to his doctrines, or of attracting students to his lectures, is probably to be traced to a similar origin.

The *Elements of Medicine*, written in Latin, first appeared in 1780. This work contains a comprehensive view of his opinions, which were more fully illustrated in his public lectures, which he delivered for several years; and, as it was his intention to prosecute the profession of medicine by private practice and public instruction, he obtained a medical degree from the university of St Andrews; the application for which at his own university, in consequence of the irritation which subsisted between him and the professors, it is supposed would have failed. But his labours, owing chiefly to his unfortunate habits, were unsuccessful. He removed to London in 1786, and having delivered a course of lectures before 1788, he was seized with apoplexy in the month of October of that year, on the very day when he had commenced a second course, and when he had reached the 53d year of his age.

A view of Brown's peculiar doctrines, which constituted his once celebrated, but now nearly forgotten system, could scarcely afford any interest to the general reader. The medical student may be referred to the work itself, or to an edition of the *Elements of Medicine*, published by Dr Beddoes, to which is prefixed a life of the author. But it may be observed in general, that the writings of Dr Brown, either from the unsettled nature of his principles, or from the obscurity of his expressions, are often dark and ambiguous, and his style is frequently harsh and unpolished; and it may be added, that the mechanical, or chemical illustration of the theory, which has been attempted by the author, or his followers, contributes little to its perspicuity.

BROWNISTS, a religious sect which appeared in England about the end of the 16th century, and derived its origin from Robert Brown, a native of Rutlandshire, who had been educated at Cambridge, and had been sometime a schoolmaster in the vicinity of London. Being admitted to the clerical profession about the year 1580, he began to inveigh openly against the discipline and ceremonies of the established church; and for this he was frequently prosecuted before the ecclesiastical courts, and subjected to imprisonment. His followers assumed the name of Brownists, and not only separated from the church, but refused to join in the public offices of religion with any other Christian society. The violence of his conduct, or the persecution which he suffered, forced him to leave the kingdom; and, with the permission of the states of Holland, he and his followers settled at Middleburgh in Zealand, and modelled their church according to their own peculiar views. But repose and freedom from restraint, seemed little congenial to the temper of these sectaries; divisions took place among themselves, and Brown, their leader, resigned his office, and returned to England in 1589. For some time his hostility to the church continued; and being again prosecuted, sentence of excommunication was pronounced against him. At last, such was his wavering conduct, he renounced his principles of separation, was restored to the church, and preferred to a rectory in Northamptonshire. But in this situation his life is represented as idle and dissolute; and in consequence of a quarrel with the constable about the payment of parish taxes, he was thrown into prison, where he died in 1630, and in the 81st year of his age.

The peculiar principles of the Brownists refer to the discipline and ordinances, rather than the doctrines of the church of England. Every society enjoyed the full power of choosing its own pastors, of regulating its own concerns, and, altogether unconnected with other congregations, formed within itself a complete church. The pastors and office-bearers of the church were appointed by the congregation, which reserved the power of removing them when the spiritual benefit of the community required it. From the sect of the Brownists, which continued for nearly 100 years, arose the Independents, whose constitution and discipline are nearly the same.

BROWNRIGG, Dr William, a learned English physician, was a native of Cumberland, and was born about the year 1712. Little is known of the early part of his life; but being destined for the medical profession, and having completed the previous requisite studies in his own country, he repaired to Leyden, the celebrity of which, at that period, attracted crowds of students from all quarters; and he had the good fortune to finish his medical education under the eminent professors Albinus and Boerhaave, whose unrivalled reputation then added the highest splendour to that university. Having obtained a degree in medicine in 1737, he returned to England and settled at Whitehaven, where he soon acquired the most extensive and the most respectable practice. Dr Brownrigg seems to have been strongly attached to chemistry, and to have devoted much of his leisure time to enquiries connected with that science. In 1748 he published a treatise *on the Art of Making Common Salt*; sometime afterwards, *an Enquiry concerning the Mineral Elastic Spirit contained in the Water of Spa in Germany*; and in 1771, a work *on the Means of Preventing the Communication of Pestilential Contagion*. In some of these investigations he approached nearly to the curious discoveries of Dr Priestley on the nature and properties of air. For the last twenty years of his life he lived chiefly at his seat near Keswick; and in this retirement he died in 1800, when he had reached the venerable age of 88, lamented by the poor, to whom he was always a beneficent friend, and regretted by all.

BRUCE, Robert, king of Scotland, was the son of Bruce, lord of Annandale, and, the countess of Carrick,—and the grandson of Robert Bruce, the unsuccessful competitor with Baliol for the Scottish throne, and was born in 1274. The father had joined the standard of Edward, and fought in the English army against his native country; but having met with Wallace, in a conference on the banks of the Carron, he was reproached by that patriotic hero for sacrificing the happiness and the independence of Scotland to

Bruce.

the ambitious views of a foreign prince; and being deeply impressed with his unnatural conduct, he exhorted his son, in his dying moments, to avenge the cause of his country. The injunctions of the father were not lost upon the son. With a bold and enterprising mind, and a vigorous constitution, he had been long inured to the exercise of arms; and the death of Wallace having deprived the Scottish patriots of their dauntless leader, he was chosen his successor. Cuming, lord of Badenoch, being his only rival for the throne, a compromise was entered into with that nobleman; but the treachery of Cuming exposed him to the suspicions of the king of England, and accelerated the execution of his plans for the delivery of the kingdom from foreign oppression. Bruce, aware of the hostile purposes of Edward, found means to escape his vigilance; and having reached Scotland, he assembled his friends, and declared his intention of assuming the crown. He was immediately acknowledged as their sovereign, and measures were adopted for restoring the liberties of their country; but as their safety and success might be endangered by the treachery of Cuming, his death was resolved on; and it is generally admitted that he fell by the hand of Bruce himself.

All reconciliation was now at an end; the vengeance of Edward was urgent, and no alternative remained for Bruce but the most abject submission, and perhaps death itself, or the vigorous prosecution of his bold design. He was crowned at Scone in 1306; but all his exertions were for a time unfortunate; his wife and daughter were made prisoners by the English; and he himself, with a few followers, was compelled to seek an asylum in Rathlin, a small island near the north coast of Ireland. Fearing that a report of his death, which was generally spread, might discourage his adherents and prove injurious to his cause, he landed secretly in Arran, and dispatched a trusty attendant to the opposite district of Carrick, his patrimonial domain, for the purpose of discovering the sentiments of his ancient vassals. He soon after followed, and when he landed with his few friends, he learned that the whole country was in possession of the English. With 300 followers he attacked the English, took the castle of Turnberry, and put the garrison to the sword; and after a severe struggle of eight years, which terminated in the splendid victory of Bannockburn, Bruce saw himself firmly seated on the throne, and the independence of his country secured. Much of the remaining part of his life was occupied in active warfare; many salutary regulations were introduced during his government; and the irregularities of a people who had been long accustomed to plunder and bloodshed were greatly checked by the wisdom and vigour of his administration. He died at Cardross in 1329, in the 55th year of his age, and the 24th of his reign. As he had often intended to visit the Holy Land, he expressed a dying request that his heart should be deposited at the sepulchre of his Saviour; and his tried adherent and faithful companion in arms, Sir James Douglas, was appointed to fulfil the pious wish of his royal master. But Douglas passing through Spain, fell in a battle against the Moors, and the heart of the king was returned to Scotland and buried in the church of Melrose.

2

Bruce.

BRUCE, James, the celebrated traveller into Abyssinia, was descended from an ancient family in Stirlingshire in Scotland, and was born at Kinnaird, the family seat in that county, in December 1730. He was instructed in classical learning at Harrow on the Hill, near London, where he was placed in his twelfth year; and he devoted a considerable portion of his leisure hours in acquiring the accomplishments of fashionable life, and in the sports of the field, and other manly exercises. Being originally destined for the profession of the law, he commenced the requisite studies on his return to Scotland, but soon relinquished them, and turned his views to a settlement in the East Indies for the improvement of his fortune. This scheme was frustrated by his marriage, and his subsequent engagement, as a partner in the wine-trade, with the brother of his wife. The mild climate of the south of France was recommended for the declining health of Mrs Bruce, with whom he repaired to that country; but she sunk under a consumption, and died at Paris before a year had elapsed from the time of their marriage.

Partly on account of grief for the severe loss which he had sustained, and the depression of spirits which succeeded, and partly on account of commercial affairs, he travelled in Spain, Portugal, and the Netherlands. Involved in a quarrel at Brussels, and having wounded his antagonist, as it was supposed mortally, he was obliged to make a precipitate retreat from that country; and, in consequence of his father's death in 1758, he returned to England. The fortune to which he succeeded was respectable, but not equal to his ambitious views; and being at first disappointed in some political schemes which he suggested to government, he was appointed consul at Algiers, that he might have an opportunity of prosecuting those plans of enterprize and discovery which he had long contemplated, and for which he had qualified himself by studying the oriental languages. He left Britain in 1762, travelled through France and Italy, and having reached Algiers, he found his residence there greatly harassed by party influence; and being removed from his official situation, he obtained the Dey's permission to examine some of the interior provinces, from which he passed over into Syria and visited the famous ruins of Balbeck and Palmyra.

Mr Bruce had now determined to undertake the arduous journey into Abyssinia, for the purpose of exploring the sources of the Nile; and as he thought it might facilitate his progress to travel in the character of a physician, he received some instructions concerning the prevalent diseases of eastern countries, as well as some books on the same subject from Dr Russel, who was then resident at Aleppo. Thus prepared, he embarked on the Nile, and sailed up that river; and in February 1769, having joined a caravan, he reached Cosseir on the Red sea, passed over to Jidda, and examined a considerable tract of the Arabian coast. He then sailed for Masuah, which is deemed the most convenient place for entering Abyssinia; and here he was detained nearly two months by the treachery and avarice of the governor. On the 15th of November he was permitted to depart from Arkeeko, and in February 1770 he reached

Gondar the capital of Abyssinia, and was fortunate in meeting with a favourable reception from the chief persons belonging to the court. He spent several months in attendance on the king; and it was not till the end of October that he set out for the sources of the Nile, the great object of his perilous enterprise. He reached this long desired spot on the 14th of November; and he describes, with peculiar warmth, the crowd of inward emotions which suddenly rushed upon his mind when he contemplated the accomplishment of his wishes. He returned to Gondar on the 19th of November; and it was not till after nearly two years' residence, and repeated solicitations, that he was permitted to leave Abyssinia. His course homewards was directed through the desert of Nubia, and he arrived at Senaar in the end of April 1772; and after being detained more than four months in a miserable and inhospitable place, in which he says war and treason seem to be the only employment of the horrid people, on the 9th of November having left Gooz, he entered upon the most dangerous part of his journey; all his camels perished, he was forced to abandon his baggage in the desert, and with the utmost difficulty he reached Assuan, upon the Nile, on the 29th of the same month. Having recovered from his fatigues, and procured fresh camels, he returned to the desert and recovered his baggage. On the 10th of January 1773, after more than four years absence, he arrived at Cairo. Ill health detained him for some time at that place; and on his return to Europe he spent sometime in France, where he enjoyed the friendship and hospitality of the celebrated Buffon; and at last he revisited his native country, after a long absence of 12 years. He employed several years in preparing the account of his travels for publication, which at last appeared in 1790, in five 4to volumes, embellished with charts and plates. He entered into a second marriage in 1776, and after a lingering illness, his wife was removed from him by death, in 1784, leaving two sons and one daughter, of which the latter only survives. When he was preparing a second edition of his travels, his labours were interrupted by a fall, in consequence of his foot slipping on the steps in front of his own house, as he attended the departure of some friends. After remaining insensible for some hours, he died on the 27th of April 1794, and in the 65th year of his age.

Mr Bruce was tall in stature, of large size, and an athletic form, but well proportioned. He was familiar with most of the modern and ancient languages, and possessed great facility in acquiring them. He was an excellent draftsman, and had some knowledge of practical astronomy; but he was extremely deficient in natural history. A little acquaintance with botany and mineralogy, very essential requisites to every traveller, would have given a great additional value to his descriptions.

When Mr Bruce's work appeared, it was violently assailed from all quarters, and it was even asserted that he had never been in Abyssinia, and that the book was a gross fabrication. Succeeding travellers, some of whom were little disposed to support Mr Bruce's credit, have involuntarily confirmed all those statements which excited wonder, and were even disbelieved when first made. To one objection, the account which he gives of his prediction of an eclipse, the time of which by some strange mistake refers to Britain, no answer we believe was ever made. The story indeed seems to be taken from a similar occurrence which happened to Columbus the great discoverer of the New World.

BRUCKER, John James, author of a history of philosophy, was a native of Swabia in Germany, and was born at Augsburg in 1696, studied at the university of Jena, where he employed himself for some time in the capacity of a private teacher; and having entered the clerical profession, he was appointed in 1740 senior minister of his native city, which was his fixed residence for the last 30 years of his life. He died in the year 1770, at the age of 74.

Brucker was the author of various works connected with literature and philosophy; but he is chiefly known by his critical history of philosophy which was first published at Leipsic in 1744, in five quarto volumes, and in an improved and enlarged edition, in six volumes, a short time before his death. This work, which is peculiarly characterised by the profound researches, great industry, and sound judgment of the author, contains a biographical sketch of ancient and modern philosophers, and a critical examination of their systems and doctrines. An abridged translation of it, by Doctor Enfield, was published in London in 1790, in two volumes quarto.

BRUGES, a city of the Netherlands, stands in a fine plain, about eight miles distant from the sea; is spacious and well built, and about a league and a half in circumference. Of its public buildings, the most conspicuous are the stadthouse, in the great market-place, remarkable for its lofty tower, which is at first square, and is surmounted by another of an octagon form, and carried nearly to the same height; the cathedral, an ancient massy edifice; and the church of Notre Dame, which is an elegant building, and its lofty spires form an excellent land-mark to ships which approach Ostend. Two magnificent tombs of gilt copper are erected in this church; and it is said that the robes of Thomas a'Becket, ornamented with precious stones, are preserved in the treasury. Hospitals and schools are numerous; and the provisions for widows and orphans is liberal and abundant.

Bruges, in the 13th and 14th centuries, was the greatest commercial city in Europe, and formed a kind of central station between the northern and southern nations; and in consequence of this prosperous trade it acquired opulence and grandeur. But its decline was not less rapid; the citizens rebelled against the archduke Maximilian, their sovereign, who, with the assistance of the rival cities of Antwerp and Amsterdam, cut off their communication with the ocean, and destroyed their trade. Dreading more disastrous consequences, the citizens submitted to the clemency of their prince; a heavy fine was imposed on the city; many of the inhabitants were banished, and more than 50 were condemned to suffer death. From this severe visitation, which happened in 1487, it has never yet recovered. In the year 1430, the order of the Golden Fleece was instituted at this place by Philip the Good, duke of Burgundy, on the occasion of his marriage with a princess of Portugal; and the property of this order, denominated *Franc of Bruges*, included a number of villages, to which important privileges were attached.

The inhabitants of Bruges, the number of which is stated at 35,000, are occupied in the manufacture of woollen stuffs, fine linens, cotton cloth, and laces, equal to those of Mechlin. Corn, and seeds for making oil, are exported in considerable quantities; and its commercial intercourse is still respectable; by means of canal and river navigation, the communication with other towns in Flanders is greatly facilitated. Vessels of 400 tons are brought to the middle of the city. Bruges is eight miles distant from Ostend, 24 miles N. E. from Ghent, and 46 miles west from Antwerp.

BRUN, Charles le, a celebrated French painter, and descended from a Scotch family, it is supposed of the name of Brown, was born in 1619, and at the early age of four discovered a strong predilection for drawing, with no other materials than coals from the hearth; and in his 12th year produced a portrait of his grandfather, which was greatly admired. In his 23d year he visited Italy; and for six years, under the tuition of the famous Poussin, and under the same roof with that artist, he studied the principles, and laboured with unremitting assiduity to improve himself in the practice of his profession. In his 30th year he returned to Paris, and was fortunate in obtaining the friendship of the minister, Colbert, and, through him, the munificent patronage of Louis XIV. who was not more distinguished by ambition, than by his liberal encouragement of the fine arts. Nominated first painter to the king, raised to the rank of nobility, and intrusted with the superintendence of the royal works, he was at last placed at the head of the academy of painting, and had the merit of extending the facilities of improvement in the art, by establishing a school at Rome for the gratuitous instruction of his countrymen. Le Brun seems to have been one of those characters who are extremely jealous of reputation, and are feelingly alive to the danger of competition. The removal of his friend, Colbert, from the superintendence of the royal edifices, and the appointment of his successor, who brought forward a rival to the artist, greatly disturbed his repose in the close of life, and, indeed, it is said, were the means of shortening the period of his existence. He died in 1690, when he had reached the 71st year of his age.

As a painter, Le Brun was distinguished by the grandeur of his designs, in the execution of which he has preserved the utmost historical propriety, just arrangement, and accurate expression; but, in colouring, drapery, and ornament, he has been less successful. His most celebrated pictures are, the battles of Alexander, the engravings of which, by Gerard Audran, have conferred almost an equal degree of celebrity on that artist; St John in the isle of Patmos; the crucifixion; and the penitent Magdalene; and, among other productions of his pencil, may be mentioned the allegorical representation of the chief events of the reign of Louis XIV. in the great gallery at Versailles. He was the author of a treatise on physiognomy, and another on the passions, which is illustrated with figures.

BRUNN, or BRINN, a city of Moravia, and capital of a circle of the same name, is finely situated on two mountains at the confluence of the rivers Schwartschaw and Surtawa, and is remarkable for the splendour and elegance of its churches and other public buildings. The sides of the hills on which it is built are covered with gardens and vineyards; the population is stated at 16,000; the principal manufactures are silk-stuffs, velvets, cloth, and hats; and it has the advantage of four annual fairs.

BRUNSWICK, a city of Lower Saxony in Germany, and capital of a duchy of the same name, was formerly an imperial city, one of the richest of the Hanse-towns, and the residence of the reigning duke, till it was annexed to the kingdom of Westphalia during the progress of the French revolution. It stands on a fine plain on the banks of the Ocker, a navigable river; is of a square form, about two miles in circumference, and strongly fortified. The ramparts are furnished with a brass-mortar of enormous magnitude; it is ten and a-half feet long, and is more than three feet in diameter; and, with a charge of 52 lbs. of powder, it throws a ball of 730 lbs. weight a distance of 33,000 paces, according to one account, and, according to another, 33,000 toises,—a statement not more incredible than remarkable for the looseness with which it is made, particularly when it is considered that the distance of 33,000 toises is equal to 38 miles. The houses in general are old, and a large proportion of them is constructed of wood; but some of the public edifices are not destitute of magnificence,—as the palace of the duke, which is furnished with a valuable collection of objects in natural history, many excellent pictures and prints, and extensive library, which is enriched by many scarce and curious bibles; the cathedral, which is adorned with some splendid monuments; several churches; the military academy; and schools and colleges for teaching the various branches of medical science.

The population of Brunswick, which has fluctuated greatly in different periods of its history, exceeds 30,000. The manufactures of linen, silk, and woollen stuffs, iron, paper, and earthen-ware, some of which were introduced by French refugees, who found an asylum in this place from religious persecution, and whom the wisdom of government encouraged, by granting them many essential privileges. Printed calico has been long a flourishing manufacture, as well as alum and sal ammoniac, which are produced of an excellent quality. *Mum*, a kind of strong beer, which derives its name from a person called Mummer, who first made it, is celebrated in many parts of Europe, to which it is exported. The invention of the spinning-wheel in 1530, is ascribed to a native of Brunswick, and a statuary by profession. Two great fairs are annually held in this place, and each is continued for 18 days, and is crowded with strangers from the chief cities of Germany, who exchange the various productions of other countries for the manufactures of the town and its vicinity. The trade in flax, yarn, and green thread is very considerable.

Brunswick, before the incursions of the French into Germany, was the capital of a duchy of the same name, and the residence of the duke of Brunswick Wolfenbuttle, who was despoiled of his territories, and fell in an action with the army of the invaders.

BRUNSWICK, New, a province of North America, and one of the four which belongs to Great Britain; is bounded on the east and south-east by the gulf of St Lawrence and the bay of Fundy; on the south by New England; and on the north and west by Canada. It is well watered with numerous rivers, some of which are navigable, clothed with extensive forests of pine, birch, maple, elm, and other timber, and enriched, especially in the interior, with a fertile and moderate soil. The numerous harbours on the coast, afford every convenience to the trade and fisheries. The sea coast abounds with various kinds of fish; it is frequented by immense shoals of herrings, and cod are very abundant. This province was settled by loyalists in 1783, after the conclusion of the American war, and in a very short time enjoyed a lucrative trade in fish and timber with the British West India islands. The privileges granted to the United States to embark in the same trade, were unfavourable to the inhabitants of New Brunswick, who could not enter into competition with equal advantages. Beside timber to a considerable extent, which is floated down the rivers to the shipping places, horses, salted provisions, and butter, are enumerated among the exports.

BRUNTISLAND, or Burntisland, a royal borough in the county of Fife in Scotland, occupies a peninsular situation on the north side of the frith of Forth, nearly opposite to Leith, consists chiefly of a single street which is pretty spacious, and has one of the most secure and commodious harbours on the coast. In former times, Bruntisland was deemed a place of importance; it was fortified by the French during the eventful period in 1560, resisted the attack of Oliver Cromwell till he agreed to certain stipulations to improve the streets and harbour, and was taken by the rebels in 1715. The remains of walls and entrenchments, constructed for its defence, are yet visible.

The population is about 2000. The trade, before the union of the kingdoms, was considerable; the herring fishery in the Forth revived the declining prosperity of the place; a large distillery and some chemical manufactories have been established; ship-building is extensively conducted, and a spacious and commodious dry dock is capable of admitting the largest frigates.

BRUSSELS, a city of the Netherlands, stands in a fertile country on the banks of the river Senne, dates its origin in the seventeenth century, and is indebted for its commencement to a bishop of Cambray, by whose piety a chapel was erected; the inhabitants of the surrounding country were attracted to the spot, and in the course of two centuries it increased to a considerable village; was first inclosed with a wall in the eleventh century; and towards the end of the fourteenth, the fortifications, as they now appear, were constructed. It became afterwards the residence of the dukes of Brabant, at a later period the seat of the Austrian governors, sustained various changes of fortune during the continental wars, and is now the capital of the kingdom of the Netherlands.

Brussels is regarded as one of the finest towns on the continent; it is defended by a double brick wall, which is about seven miles in circumference, is furnished with seven gates, and is surrounded with extensive and populous suburbs. The older streets, and those in the lower part of the town, are narrow and crooked; but those of a modern date are spacious and elegant. The palace of the former dukes, and the usual residence of the governors, occupies an elegant situation with a spacious square in front, which is adorned with brazen pillars, surmounted by statues of emperors and dukes. This splendid structure was begun in the thirteenth century, and was not completed till the commencement of the sixteenth. The Hotel de Ville, a magnificent Gothic structure, with a spire of curious architecture, 364 feet high, and surmounted by a statue of St Michael with the dragon, in gilt copper, stands in the great market-place. The internal decorations of this splendid edifice correspond with its external magnificence. Some of the apartments are adorned with beautiful specimens of tapestry, representing the history of the resignation of Charles V. Many of the churches and palaces of the nobility are elegant structures, and most of them are richly decorated with the finest paintings, by some of the first masters of the Flemish school. Of twenty public fountains which supply the city with water, some of them are elegantly executed, and richly embellished.

The population of Brussels, of which the visitations of war, to which it has been so often subjected, has produced great variations, is stated at more than 70,000. It has been long celebrated for its manufactures. Brussels lace and Brussels carpets, always denote something of superior beauty and excellence. Woollen and cotton stuffs, silk stockings, gold and silver lace, earthen ware, and the preparation of potash, are also enumerated among its manufactories. The trade of Brussels was at one time considerable; and at an annual fair held in October, which was attended by merchants from all parts of Europe, very extensive commercial transactions were effected.

Brussels was the head quarters of the British troops on the eve of the memorable battle of Waterloo; and, both before and after that decisive victory, presented a scene of the deepest interest, not merely to its anxious inhabitants, who were fearfully apprehensive of the dreadful fate that awaited them in case of disaster, but to every nation and country of Europe, all of whom were more or less remotely concerned in the issue of the contest. But that important period of its history is still fresh in recollection; and the numerous tours, sentimental, descriptive, or of a mixed character, which the vanity or industry of its visitants has presented to the public, furnish ample materials to render the city and surrounding scenery as familiar to readers as any town and district of their own country.

BRUTE, the general appellation of those classes of animals which are either destitute of the powers of reason, or, possessing them in a lower degree, are comparatively considered inferior to man. The discrimination of the faculties, by the operation of which the various races of living beings are guided in their actions and pursuits, and the attempts to establish a distinction between the mental powers of man and the analagous principles of the inferior orders of animals, have been the fertile sources of speculative discussion in all ages. By some it is maintained, that the capacities of brute animals are not only different from the powers of man in degree, but are also of a different nature; but according to another opinion, these powers are of the same kind, and differ only in degree. Many of the difficulties which have attended this discussion might probably vanish by stricter attention to correct definitions of the terms employed, and particularly to the precise meaning of the words reason and instinct, of which the former is appropriated to the human faculties, and the latter is applied to the active principles of the inferior animals. The distinction between the reasoning powers of man and the instincts of the lower animals, proposed by Dr Reid, may help to settle this question, or at least may mark the difference between the human race and other animals. According to that cautious philosopher, the improvements, which are the result of the reasoning powers of man, are communicated and received by others, and transmitted, with all their advantages, to future generations; but however nearly the instinctive habits of some animals may approach to the rational capacities of mankind, no effort of ingenuity induced by any change of circumstances or mode of life passes from one individual to another, or is communicated to their posterity. It can scarcely be doubted, that passions and emotions of a character similar to those which agitate the human breast operate powerfully on many of the lower animals; but the observations of naturalists have discovered in them no traces of moral capacity or religious feeling, no indications of a clear perception of virtuous actions, or of veneration for a supreme being, a sentiment universally impressed on the human mind; and this remarkable diversity of mental or intellectual capacity affords another striking distinction between the powers of the human race and the lower orders of animals.

BRUTON, or Brewton, a town of Somersetshire, stands in a pleasant situation near the head of the river Brew, and is a place of considerable antiquity, as appears from the date of its free school, almshouse, and other public edifices. The population exceeds 1600; and stockings, coarse woollen stuffs, and silk throwing, by means of machinery, are the only manufactures.

BRUYERE, John de la, a French writer, who was born about the year 1664 and died in the year 1696, and of whom little is recorded, excepting that he was the author of a singular production, in which, under the general title of *Characters*, he describes the manners of his age, in imitation of Theophrastus. On this work Voltaire has pronounced the following critique: "The characters of Bruyere," he says, "may justly be ranked among the extraordinary productions of this age. Antiquity furnishes no examples of such a work. A style rapid, concise, and nervous; expression animated and picturesque; an use of language altogether new, without offending against its established rules, struck the public at first, and the allusions which are crowded in almost every page, completed its success. When La Bruyere shewed his work in manuscript to Malesieux, this last told him, that the book would have many readers, and its author many enemies. It somewhat sunk in the opinion of men when that whole generation, whose follies it attacked, were passed away; yet, as it contains many things applicable to all times and places, it is more than probable that it will never be forgotten."

BRYANT, Jacob, a profound English scholar, and writer on mythology, was born at Plymouth in 1715, received the first elements of his education at a provincial school in Kent, was instructed in classical literature at Eton, and prosecuted the higher branches of learning at King's college, Cambridge. He was afterwards employed as private tutor to the eldest son of the duke of Marlborough, aud in that capacity accompanied his noble pupil to Eton. In 1756 he was appointed private secretary to the duke of Marlborough, who was then at the head of the forces in Germany, and he attended the commander-in-chief on the continent. By the influence of the duke, who was master-general of the ordnance, he was nominated, on his return, to a lucrative place in that department. This appointment not only afforded him that leisure and competency which are so desirable to a literary man, but brought him that affluence which enabled him to appear with respectability in an extensive circle of literary friends and persons of distinction. The greater portion of Mr Bryant's long life was marked by studious and retired habits. His residence was chiefly in the vicinity of Windsor; and his mild manners, elegant conversation, and extensive knowledge, rendered him an agreeable companion in the most polished society. He lived to his 89th year, and died in 1804. He bequeathed his valuable library to King's college, Cambridge, the liberal sum of L.1000 to the Society for the Propagation of the Gospel, and L.1000 to the superannuated collegers of Eton.

The works of Bryant furnish undoubted evidence of profound erudition and unwearied industry; and his labours were chiefly directed to the elucidation of classical literature or scripture history. His treatise on *Ancient Mythology* is acknowledged to be his most elaborate production; and the last work in which he was engaged, and to which his thoughts had been directed for 30 years of his life, is entitled, *Dissertations on Various Subjects in the Old Testament*; but the classical reader may perhaps be surprised, that the same person who vindicated the authenticity of the poems published by Chatterton, and ascribed to Thomas Rowley, has attempted to prove in another work, that no such city as Troy existed in Phrygia, and, consequently, that the history of the Trojan war is an invention of the Greek poet.

BRYONIA, Bryony, a genus of plants belonging to the class Monœcia, and of which one species, *Dioica* or *Alba*, Red-berry Bryony, is a native of England.

BUCCANEERS, an appellation originally applied to the French settlers in the island of St Domingo, who lived by hunting wild cattle; but it was afterwards extended to a set of piratical adventurers, composed of English and French, who associated for the purpose of making depredations on the Spaniards of

America. The name is said to be derived from a practice of the indigenous inhabitants of the Caribbee islands, of roasting the prisoners of war over a fire. The operation was called *boucaner*, to roast and smoke; and as the hunters practised the same thing on animals killed in the chace, they were denominated Buccaneers. The success of the Spaniards in obtaining possession of the West Indies and continent of America, and the riches which they acquired, excited the avarice of other nations, especially the English and French, to come in for a share of the booty. The jealousy of the Spaniards was alarmed, and a settlement of the French in St Christophers was driven from that island. Thus disappointed, some of the fugitives retired to the northern shores of St Domingo, which were then uninhabited, and fully stocked with countless numbers of wild cattle and hogs. Along with some English and Dutch adventurers, they took possession of those parts of the island, and devoted themselves to the hunting of those animals. Some of them became planters, and many turned pirates, and obtained the name of freebooters. The riches which these piratical adventurers obtained, and distributed among their associates, drew numbers from Europe, who joined them in the character of indented servants: And thus the colony was composed of four classes; the buccaneers, or hunters, the planters, the free-booters, or pirates, and the indented servants. The planters settled chiefly in the small island of Tortuga, on the northern coast of St Domingo; but, during the absence of some of them in the latter island, the rest were surprised by the Spaniards and put to death. An attempt was next made to drive the buccaneers from St Domingo; and the greater part of the cattle being destroyed by the Spaniards, some of the hunters joined the French settlement on the coast, and others united themselves to the freebooters, who then became a powerful body.

The piratical adventurers who arose among the buccaneers, formed themselves into small parties of 50, 100, or 150 men each, and, with vessels of different sizes, directed their depredations, at least in the first period of their career of plunder, chiefly against the Spaniards; but afterwards, from choice or necessity, made a prey of the property of other nations. Their attacks were not confined to the rich ships of the Spaniards returning to Europe, but were extended, as their numbers and audacity increased, to their settlements both on the east and west shores of South America, and in many cases they carried off immense plunder. The buccaneers flourished during the 17th century, and, as a proof of their power and influence, 1200 of them joined a French fleet sent from Europe to attack Carthagena; and, by their valour and exertions, the city was taken, and booty obtained to the value of a million and a-half Sterling; but the avidity of the commander offered them little more than L.5000 as their share of the spoil. It was rejected with disdain; they returned to the city, and entered it without resistance; shut up all the men in the great church, and demanded payment of L.218,750 as their share of the prize-money; but as the sum collected fell short, the city was plundered. Returning loaded with wealth, the buccaneers fell in with a fleet of English and Dutch ships, who were then in alliance with Spain; several of the pirates were taken or sunk, the rest escaped to St Domingo, and this was the last memorable event in their extraordinary history. Of these adventurers it has been remarked, that without any regular system, without laws, and without any fixed revenue, they became the astonishment of the age in which they lived, as they will be also of posterity. See Edward's *History of the West Indies*; Raynal's *History of the East and West Indies*; *History of the Buccaneers of America*, by J. Esquemeling.

BUCCINUM, or WHELK, a genus of testaceous animals, belonging to the order of Univalves, and of which several species are natives of Britain. See CONCHOLOGY.

BUCENTAUR, a large galley, belonging to the state of Venice, which was finely adorned with pillars, splendidly gilt, and furnished with a covering of purple silk. In this vessel the doge received the great lords and persons of quality who visited Venice, accompanied by the ambassadors, counsellors of state, and senators; and the same vessel was employed on Ascension-day, in the magnificent ceremony of espousing the sea, by throwing a ring into it, as a symbolical expression of the dominion of the Venetians over the gulf.

BUCER, MARTIN, a learned German, and one of the early promoters of the Reformation, was born about the year 1491; assumed the religious habit of St Dominic while in his 7th year; but his future inquiries and conversation with Luther excited doubts concerning the Romish faith, and led him at last to join the reformers. He assisted at many conferences on religious matters, and was present at Augsburg, where he subscribed the agreement between the papists and protestants, called the *Interim*. Exposed to severe persecution in his own country, he was invited into England by archbishop Cranmer, and appointed to teach theology at Cambridge, where he died in 1551, and was buried with great funeral pomp. Five years afterwards, and in the succeeding reign, when the fury of persecution reached the dead, his body was dug up and publicly burnt, and his tomb destroyed; but it was again repaired by the order of queen Elizabeth.

BUCHANAN, GEORGE, a Scottish poet and historian, celebrated for the elegance and purity of the Latin language, which he usually employed in his writings, was a native of the parish of Killearn in Stirlingshire, and was born in the year 1506. On the death of his father, who was a small farmer, the charge of a young family of five sons and three daughters devolved to his widow, who was left in a state of great poverty. George, it is said, received the elementary part of his education at the public school of his native parish; and through the kindness and liberality of James Heriot, his maternal uncle, he was sent, in his 14th year, to the university of Paris, where he improved his knowledge of the Latin language, began the study of Greek by his own industry alone, and first discovered his talents for poetry. Two years had scarcely elapsed when the death of his uncle threw him friendless on the world, and at the very time when he was afflicted

Buchanan. with severe indisposition. He returned to Scotland, and his health being restored, he entered the army, and spent about a year in active warfare in England. But his constitution was unequal to the hardships of a military life, which hurt his health and threw him on a sick-bed for several months. About the end of his 18th year he entered the university of St Andrew's, and in 1525 was admitted to the degree of bachelor of arts; soon after became a student in the Scotch college at Paris; was afterwards appointed a professor in the college of St Barbe, and taught grammar for three years. In 1532 he had the good fortune to be appointed tutor to the earl of Cassillis; and after five years residence in France, he returned with that young nobleman to Scotland.

The inquiries in which Buchanan had been engaged, and the intercourse which he held with learned men who were attached to the reformed religion, led him to adopt their sentiments and opinions, and made him little scrupulous of exposing the dissolute conduct of some of the members of the Romish church. The publication of a satirical poem, after his return to his native country, in which he reflected on the Franciscan friars, excited the obloquy and resentment of that order, and determined him, to elude their threatened vengeance, to take refuge in France. But the appointment of preceptor to James Stuart retained him in the country till the publication of his *Franciscanus*, in which the ignorance and vices of the same order are still more fully exposed and treated with ridicule, brought him into immediate danger, and obliged him to make a precipitate retreat to London, and afterwards to Paris. The relentless persecution which he dreaded from cardinal Beaton, who was then ambassador at the French court from Scotland, drove him from Paris to seek an asylum in the college of Guienne at Bourdeaux, where he was nominated professor of the Latin language, was happy in the society of some of the most eminent scholars of the time, and in the course of three years wrote his translations of two tragedies of Euripides, and two original compositions of the same character, the subjects of which are taken from scripture history.

After a residence of three years at Bourdeaux, Buchanan returned to Paris, where he was employed as a professor in the college of cardinal le Moine, and had for his associates Turnebus and Muretus, two of the most learned men of the age. About this time the university of Coimbra was established in Portugal, and the reputation of Buchanan, through the recommendation of his friend, Andrew Govea, whom he had formerly known at Paris, procured for him an invitation to take a share in the management of that seminary; but the unexpected death of Govea left him exposed to the intolerance and persecution of religious bigotry. He was charged with heretical practices, summoned before the inquisition, and with a lenity not usual with the decrees of that dread tribunal, was only sentenced to confinement in a monastery. The period of his imprisonment was one of the most important in the literary life of Buchanan; for, during that time, he composed his version of the Psalms, a task, it is said, imposed upon him by the monks to whose charge he was intrusted, either as a punishment, or as evidence of the soundness of his faith. But whether the labour of this beautiful composition was imposed upon him by others, or was the spontaneous effort of his own genius, the purity of its style, and the elegance of its language, have raised the author to the first rank of Latin poets in modern times.

Having regained his liberty, he turned his thoughts to France, which was always his favourite residence, and which on this occasion he eulogises in a fine strain of panegyric, and delineates, with all the embellishments of poetry, the beauties of the country, and the refined manners, distinguished valour, and liberal arts of the people. Several years of his life were at this time spent in France, either in the capacity of a public teacher in some of the seminaries of Paris, or as a private tutor in a noble family. But the flames of civil war again drove him from the French territory, and obliged him to revisit his native soil. When he returned to Scotland the reformed religion had been sanctioned by a parliamentary enactment, and he now declared himself a professed adherent of the new doctrines.

The learning, prudence, and respectable character of Buchanan, pointed him out to Queen Mary as a fit person to superintend the education of her son. At an earlier period, he had assisted the studies of that unfortunate princess in classical literature, and the dedication of his version of the Psalms, in an elegant poetical address, shews that he either enjoyed or courted royal favour. Mary in her turn was not unmindful in rewarding his merits. She conferred on him the temporalities of the rich abbey of Crossregal in Ayrshire; and he was nominated principal of St Leonard's college in St Andrews, till the young prince should arrive at a proper age to benefit by his instructions. At a future period of his life he held the office of director in chancery and lord privy-seal; and to retain his services and influence in her interest, he enjoyed from queen Elizabeth a pension of L.100 a-year. Having joined the party which opposed the views and conduct of the ill-fated Mary, Buchanan produced a work, entitled the *Detection*, which, it is said, was written at the suggestion of the regent Murray, and which is read with sentiments of censure or applause, according to the view which is adopted of the strange transactions to which it alludes. He accompanied the same nobleman on an embassy to the court of Elizabeth, on the affairs of the Scottish queen, who was then prisoner in England. In 1579 appeared a celebrated work, in which he discusses some of the principles of government; it is entitled *De Jure Regni apud Scotos Dialogus*, and is dedicated to his royal pupil; and in his 74th year he composed a Biographical Sketch of himself, which is not more distinguished by elegance of language than modesty and candour of sentiment. The last twelve years of his life were devoted to the preparation of his History of Scotland, a production which is advantageously compared with the best Roman writers for its classical purity and elegance, but which has not escaped the charge of partiality, and an undue attachment to the detail of fabulous events. While this celebrated work was in the press, the author was seized with his last illness, and he died in

September 1582, when he had reached the 77th year of his age. His body was committed to the earth in the burying-ground of the Greyfriars; but no memorial remains of the spot where his ashes repose,—no stone marks the place of his dust. An obelisk, 100 feet in height, which was erected in 1788, at Killearn, points out to the traveller the place of this great scholar's nativity.

Throughout his works Buchanan exhibits himself the resolute enemy of tyranny and usurpation, and the steady friend of the liberties of mankind. His happy genius, as the historian of the period in which he lived finely expresses it, equally formed to excel in prose and verse,—more various, more original and elegant than that of any other modern who writes in Latin, reflects, with regard to this particular, the greatest lustre on his country.

The best editions of the collected works of Buchanan are one which was printed at Edinburgh in 1704, in 2 vols. folio, and another in 2 vols. 4to, revised by the learned Burman, and published at Leyden in 1725. See *Memoirs of the Life and Writings of Buchanan*, by Dr Irving.

BUCHARA, or Bokhara, a city of Great Bucharia, in Asia, is situated on an elevated spot on the banks of the river Sogd, and is about 100 miles westward from Samarcand. The city is divided into three quarters, of which the khan, or governor and his court, occupy one; his officers and servants another; and the third, the most extensive, is assigned to the merchants and other inhabitants; and in this last subdivision, every particular trade has its own department. The houses are low, and generally composed of mud; but the public buildings, such as the mosques and baths, are constructed of more substantial materials. In an early period of its history, Buchara was celebrated for its university, to which students crowded from all parts of the Mahometan dominions, to be instructed in the various branches of literature.

Buchara was famous for fine linens in the 10th century; but its chief manufactures, in modern times, are cotton stuffs, printed calico, and soap. Its favourable situation for trade, raised it to great commercial importance, and it became an emporium for the exchange of the productions and commodities of the east, for those of the western parts of Asia and Europe. But since the subjection of the country to the Usbeck Tartars, it has greatly declined, and its commerce has languished under injudicious and oppressive exactions.

BUCHAREST, or Buchorest, a town of Wallachia, in European Turkey, stands on the river Damboriza, and is the residence of the prince or governor of the province, and the see of a Greek archbishop. The houses, which have in general a mean appearance, are spread over a great extent of surface, and may be considered as a collection of villages, distributed without any regular plan. The streets have a singular appearance from being paved with planks of wood laid transversely, and when this unusual pavement begins to decay, walking becomes extremely incommodious. The number of convents and churches is said to be not fewer than 400, and some of them are elegantly constructed in the Greek style. The palace of the Hospodar, or governor, is a low building of wood, destitute of elegance. The population of Bucharest is stated at 60,000. The surrounding country possesses a fertile soil, affords excellent pasturage, and abounds in corn and wine, from which are derived the chief commodities of their trade, which consists in the exportation of provisions to Constantinople. At different periods subject to the Russians, the Austrians, and the Turks, Bucharest came under the dominion of the latter power in 1791, and has since continued to acknowledge the authority of the Ottoman porte. It is about 250 miles N. W. from Constantinople.

BUCHARIA, or Bocharia, Great, a country of independent Tartary, which is bounded on the north by the river Sirr, and on the south by a chain of mountains which form the limits with Persia and Hindostan, and on the east by a chain which separates it from Little Bucharia. This country is supposed to include the Sogdiana and Bactria of the ancients; it lies between 35° and 43° of north latitude, and 59° and 73° of east longitude, and comprehends the kingdoms of Samarcand, Balk, and Bucharia properly so called. It presents an agreeable variety of surface; the mountainous ridges are extensive and lofty; and the plains are copiously watered by the Amu or Jihon, which is the Oxus of the ancients, and the Sirr or Sihon, both of which discharge their waters into the lake Aral, the latter after a course of 350 miles, and the former after having run nearly 900 miles. The climate is favourable, and the soil is said to be the richest in northern Asia. Corn and rice are cultivated in some places, but the most fertile parts of the country are always in pasture, on which is reared a prodigious number of sheep and horses. Of horses, it is said that 10,000, and of sheep 60,000, are annually sold at Orenburg in Russia. The mountains furnish some metallic ores, and even some of the precious metals have been discovered.

The inhabitants of this country consist of three distinct nations, the Buchars who are the native race, the Moguls, and the Usbeck Tartars to whom it is now subject. The first, or the Buchars, are quiet and mild in their manners, compose the chief population of the towns and villages, and are entirely devoted to trade and commerce; but the other two tribes of inhabitants are of a robust and warlike character, delight in martial exercises, and are rarely disengaged from feuds and hostilities with the Persians. The Tartars are governed by khans, to whom the native inhabitants pay an annual tribute. The original race of the Buchars enjoy the greater part of the trade, and carry on an extensive commercial intercourse with China, Russia, and Tibet.

BUCHARIA, Little, a country of Asia, which was formerly known under the denomination of the kingdom of Cashgar, and is supposed to include part of ancient Scythia. Inferior in the nature of its soil, its climate, population, and the number of its cities, it is distinguished by the title of Little; but not because it is less extensive than the country on the west which has a similar appellation. The Altaian mountains form the boundary on the north, the empire of China is on the east, and a chain of mountains marks the line of separation with Tibet on the south. Included between the 36 and 44° of north latitude, and the 70 and 88° of north longitude, it is about a thousand miles in length, and nearly 500 miles at its greatest breadth. It is nearly surrounded with lofty mountains and sandy desarts. The soil is generally barren and unproductive; but in some of the fertile vallies, cotton, hemp, flax, vines, and different fruits, are abundant and excellent. The inhabitants, in their manner and dress, resemble those of Great Bucharia; and their chief trade is with China, Persia, and the northern parts of Asia.

BUCKING, the first operation in bleaching, or the preliminary process in preparing cloth for being whitened. See Bleaching.

BUCKINGHAMSHIRE, an inland county of England, is bounded on the north and east by the counties of Northampton, Bedford, Hertford, and Middlesex, and on the south and west by Berkshire and a part of Surrey, from which it is separated by the river Thames. The name is supposed to be derived from a Saxon word, in allusion to the beech trees with which the country was covered, or, according to others, from bucks or deer which once abounded in its forests. The Chiltern hills, which consist chiefly of chalk, occupy the southern districts of the county; but the northern division is finely diversified with eminences of moderate elevation. The chief rivers are the Ouse and the Thames. The length of the county is about 45 miles, and the breadth about 18 miles, including more than 518,000 acres, of which more than two-thirds are arable.

The population of this county in 1811 exceeded 117,000. It is divided into eight hundreds and 185 parishes, with 15 market-towns, of which Buckingham and Aylesbury are county towns. Some of the nobility and gentry have splendid residences in this county, among which the magnificent mansion and spacious grounds of Stowe, belonging to the marquis of Buckingham, are the most conspicuous.

The soil of the county is chiefly of rich loam, strong clay, or chalky. Grain is produced in the Chiltern district, but a small portion only of the northern division is arable. The vale of Aylesbury, in the centre of the county, has been long proverbial for its fertility, and affords a rich pasture to great numbers of cattle. The dairy is the chief object of attention in some parts of the county, and a large quantity of butter is annually made for the supply of the London market. The rearing of calves and of young ducks, the latter of which, by particular management, are brought forward about Christmas for the supply of the same market, are also much attended to.

Lace and paper are the chief manufactures, in the former of which almost all the females of the lower classes are employed. The manufacture of paper is in the vicinity of Wycombe, and on the small river of the same name fifteen corn and paper-mills have been erected; cotton spinning has been established; and wooden vessels and utensils of turnery ware are made at Chesham. The trade is greatly facilitated by the grand junction canal, and by smaller branches which traverse the county.

Some remains of Roman antiquity have been discovered in this county, among which are enumerated coins, and vessels, and particularly a fine tesselated pavement of about nine feet square, the borders of which are beautifully ornamented with small square stones of different colours, and the centre is occupied with the figure of an animal. This pavement was found in the neighbourhood of Wycombe.

BUCKINGHAM, Town of, is the chief town of the county of the same name, stands on the banks of the river Ouse, and is washed on three sides by that stream, consists of one long street, and the houses, which are chiefly of brick, are scattered over a large space. The church, a modern edifice, on an elevated spot, and adorned with a square tower, which is surmounted with an elegant spire, and the town hall, are the principal public buildings. The population exceeds 2600, and the inhabitants are chiefly occupied in the labours of agriculture, and in the manufacture of fine black and white thread lace.

BUDA, the capital of the circle of Pest, and the chief city of Hungary, stands on an elevated spot on the west bank of the Danube, is the *Acinium* of the Romans, and on the opposite bank of the river is Pest, the *Contra-Acinium*, with which a communication is formed by means of a bridge of boats. Buda is called Offen by the inhabitants, and in conjunction with the opposite town of Pest, is generally described as one place. It has neither walls nor gates, but is defended by a castle on the eastern extremity. The suburbs, which are occupied by Jews, have the name of Jews-town. When Buda was the seat of royalty, it was the finest city of Hungary; but under the dominion of the Turks, who held it during the long period of 150 years, it fell to decay, and mosques and minarets took the place of some of the principal churches. The caravanseras and mosques are still reckoned among the principal buildings; but the most magnificent edifices are the warm baths, which have been long famous, and places of great resort. Pest is surrounded with a wall and moat, and the royal palace, a spacious edifice, the military hospital, some convents and churches, are the principal buildings. The university is the first learned institution in the kingdom, and more than thirty teachers are established for giving lectures in divinity, philosophy, and medicine.

Buda is the chief commercial city in the kingdom. The productions of the soil and of national industry are the principal exports, among which are enumerated grain, tobacco, brandy, potash, honey, wax, and the famous Tokay wine. The fair of Pest, which is attended by Greeks, Jews, and Armenians, and lasts for ten days, is the greatest in Hungary. The population of Buda exceeds 20,000 inhabitants, and that of Pest is from 25,000 to 30,000.

Buda was the residence of the Hungarian monarchs till the year 1410, when Sigismund was raised to the imperial throne of Germany. After several times changing masters, it finally came under the dominion of the Austrians, and continued in their possession till 1686. The public offices which had been established at Presburgh, were transferred to Buda in 1784, and gave a considerable accession of wealth and population. Buda is 125 miles S. E. from Vienna.

BUDISSIN, or Bautzen, the capital of Upper Lusatia in Saxony, stands on the river Spree, and was founded by a duke of Bohemia in the 8th century, was formerly an imperial city, but lost its privileges when it fell under the dominion of the king of Bohemia. The manufacture of woollen stuffs, linen, and stockings is extensive, and the printing of linen and cotton cloths, with the preparation of glazed leather, furnishes employment to many of the inhabitants.

BUENA VISTA, or BONAVISTA, one of the Cape de Verd islands, on the west coast of Africa, and in north latitude 15° 56′, derives its name from the fine appearance which it presents to those who approach it from sea; is about 20 leagues in circumference, and is particularly distinguished on its northern boundary by a remarkable ridge of white rocks.

BUENOS AYRES, a viceroyalty of the Spanish dominions in South America, is bounded on the north by Brasil and Amazonia; on the east by Brasil and the Atlantic ocean; on the south by Patagonia, and large tracts of country still imperfectly known; and on the west by Chili and Peru. The area within these boundaries is from north to south about 1600 miles long, and from east to west more than 100 miles broad; and comprehends the provinces of Rio de la Plata, Paraguay, Tucuman, Los Charcos, and Cuyo.

External aspect.—This extensive region exhibits, on a great scale, a series of the more prominent physical features impressed on the earth. A majestic river, which expands to the breadth of 150 miles, and rolls vast volumes of water into the Atlantic, is, at no great comparative distance from its mouth, ramified into several noble branches, which penetrate far into the frontier mountains, and which collect and carry off the floods of rain that frequently falls upon them. From the banks of these rivers, the country expands into wide and trackless plains, waving in one place with luxuriant grass—where innumerable flocks and herds roam unconfined, and where game of many sorts find their food, and their shelter; in another place they are covered with impenetrable forests of gigantic growth, the retreats of birds, and the lurking place of wild beasts; here a hollow basin, hundreds of miles in circumference, becomes an azure lake, or a reedy marsh, which harbours noisome reptiles, and exhales pestiferous vapours; there stupendous mountains, white with eternal snow, or red with blazing volcanoes, lift their heads above the clouds. Thus the sublime mountains, the majestic streams, and the expansive plains of Buenos Ayres, present a scene of unparalleled magnificence, in comparison of which the corresponding objects of other regions dwindle into insignificance.

Mountains.—Except where this vast amphitheatre opens to the ocean, it is surrounded by lofty cordilleras, of which the stupendous Andes traverse its upper provinces. From the principal ridges on the western frontier, a lateral branch stretches eastward between the territories of the Portuguese and the Spaniards, and contains the sources of the great rivers which cross and divide the countries both of Brasil and of Buenos Ayres. A similar ramification in the direction of the river Colorada forms the southern frontier, and a variety of intermediate chains, of which the mountains of Cordova and Achala are most conspicuous, extend through the province of Tucuman.

Rivers.—From these mountains a thousand streams descend, and, having traversed the interior part of the country in all directions, unite in one immense estuary, which is distinguished by the name of the Rio de la Plata, and which affords a magnificent approach to the inland provinces. In tracing the Rio de la Plata upward from the ocean along its northern bank, the Uraguay is the first great river which swells its waters. This river rises in the Sierra de St Catherine mountains, which wall the southern coast of Brasil, and thence, in a channel of a thousand miles in length, flows toward the Rio de la Plata. At its mouth it is four miles broad, but in many places of its course it spreads out to double that extent. The right bank of this river is steep and rocky, but the left is low and marshy; it is increased by many tributary streams, and is navigable to Yupoya where it is obstructed by a fall. Above the mouth of the Uraguay, the Rio de la Plata bends towards the north, and assumes the name of the Paraguay, the sources of which are traced to the Diamond mountains of Brasil. The water of this river, while it flows among the mountains, is highly transparent, but, being impregnated with a saline substance, it has a nauseous taste. This salt matter deposits an incrustation on the roots of the trees on the margin, which gives them the appearance of rock-work. Having received the Cipotuva, the Cabacal, and the Jaura, the Paraguay leaves the mountains and enters the great flooded savannahs. The Parana, which is the eastern and the greater branch of the Paraguay, flows also from the mountains of Brasil; at the place where it enters the Cordillera de Maacayu, it is 2100 fathoms broad, nearly a sea league, and very deep; but the mountains contract it so suddenly to a channel of thirty fathoms, and in these straits the whole body of water falls more than fifty feet at an angle of fifty degrees. The sound of this tremendous cataract is heard to the distance of six leagues, and a cloud of vapour rises to an immense height, and falls in a perpetual shower. The fish are of different species above and below the fall, and thence to the mouth of the Yuguazu, a distance of thirty-three leagues, its course exhibits a constant succession of rapids and whirlpools. The rich savannahs on the banks of this river are scarcely habitable; for they are subject to two inundations in the course of the year, and beyond the flooded country there is no water at all, or water so bad as to be unfit for use. These great rivers, as they flow in their courses, are joined by innumerable smaller streams; of these, the Pitcomayo, the Vermejo, the Salado, which flows into the Paraguay from the west, deserve particular notice. The Saladillo, after traversing the southern plains of the province of Buenos Ayres, loses itself in the great bay formed by the Rio de la Plata. The Rio Colorado, denominated at different parts of its course also the Desaguodora, the Mendozo, &c. has its source among the mountains bordering on Chili, and its mouth on the north side of cape Lobos, and may be regarded as the natural boundary of the viceroyalty on the south.

Lakes.—The physical causes, of which, in other regions, lakes are the effect, operate here with a power proportioned to the influence necessary to produce stagnate surfaces of water of a magnitude sufficient to correspond with the other objects which diversify the face of the country. The pent up vallies become the reservoirs of the torrents which furrow the face of the surrounding mountains; or the rivers overflow their banks, and lodge their waters in the hollow places of the neighbouring plains. Lakes formed in both these ways abound throughout Buenos Ayres. The mountain vallies of the province of Cuyo, Los Charcos, and the upper parts of those of Tucuman and Paraguay, are thickly interspersed with lakes of the former description; of these the lake Titicaca, situated among the Andes, in the province of Los Charcos, exhibits the most magnificent aspect. It is about 240 miles in circumference, and from 70 to 80 fathoms in depth; it presents an irregular outline, deeply indented by capes and creeks; its waters are brackish and muddy, but its banks are finely diversified, and extremely fertile; many picturesque islands are scattered on its surface, over one of which stood the most splendid of the Inca temples. The lake Xarayes spreads over an immense surface, between the 16th and 18th degrees of south latitude. This wide space is flooded by the inundations of the river Paraguay, and is alternately an inaccessible marsh, and a navigable sea. The lake Iberi lies between the Uraguay and the Parana, and is said to be formed by a filtration of the waters of this latter river through the sand of which the subsoil is composed. Besides these lakes, the Aguaracaty, the Ypoa, the Neembucu, the Mandiha, the Yapacarary, and a multitude of others, are found expanding from the river courses after they have reached the great plains.

Climate.—The geographical position, and the diversified surface of this country, indicate much difference of temperature. The ordinary summer heat of the plains which approach nearest to the equator, is from 85° to 100° of Fahrenheit's thermometer placed in the shade, and that in the coldest months in winter it is seldom seen below 45°, while in the same latitude the mountains ascend sublimely far above the region of perpetual frost, where

> Thron'd in his palace of cerulean ice,
> There Winter holds his unrejoicing court,
> And through his airy hall the loud misrule
> Of driving tempests is for ever heard.

In the sloping declivities of these snow capped mountains every gradation of temperature, from the extreme cold of the summits above to the oppressive heat of the plains below, is experienced at short intervals. The excessive evaporation perpetually going on from the lakes, rivers, and forests, loads the atmosphere with humid vapours which, in many cases, prove injurious to the health of the inhabitants, render the houses extremely damp, and generate the most terrific storms. Amid the violent raging of these storms, the appalling glare of livid lightning extends over the horizon, the awful peal incessantly rolls in the heavens, and the tremendous thunderbolt deals destruction to every object exposed to its terrible influence. Hurricanes are said to be of rare occurrence, and it is said, at the same time, that the gales which frequently sweep over the Pampas plains, carry with them clouds of dust so dense and dark as to intercept the light of the sun, and that they blow with a violence which makes it necessary to use mica, instead of glass, in the windows of the houses in the towns of Paraguay. These south winds, as also those which blow from the east, lower the temperature, and generally usher in the annual rains. Yet, notwithstanding these circumstances, which, indeed, are confined to particular spots, or to particular periods, the climate of this country is, on the whole, one of the most delightful in the world. Such is its kindliness, that the salubrious amenity of the atmosphere at first suggested the name *Buenos Ayres*, or *fine air*, which the principal city and the country at large still retain; and the surprising energy of vegetation, the unparalleled fecundity of animal existence, as well as the health and longevity of its inhabitants, prove the appellation to have been properly applied.

Minerals.—The mountains which surround, or which traverse this country, are constructed chiefly of primitive rocks, and accumulations of volcanic scoria. These mighty masses are rich beyond all parallel in beds of useful fossils, and in veins of metallic ores. The plains below the western mountains are completely saturated with common salt, to the enormous extent of 700 miles in length, and nearly 200 in breadth. The greater part of this saline region is interspersed with numerous and extensive lakes full of strong brine, and lined with a thick incrustation of solid salt; in many places of the tract, too, this substance is found in a dense efflorescence upon the surface. Great quantities of this valuable mineral are collected and purified on the spot, and thence conveyed to the cities and towns of the vice-royalty.

Mines of gold, silver, &c.—But this country is still more distinguished for its metallic ores than for its saline productions. According to Helms, who, from the records of the chancery, constructed a table of the mines now worked in the vice-royalty, there are at present open in it 30 mines of gold, 27 of silver, 7 of copper, 9 of lead, and 2 of tin. Grains of gold are found in many of the river courses; of which the sand of the river Vermejo, and that of a stream near the Indian town Mexos are peculiarly rich. A productive mine of this precious metal is now open in the district of Monte Video. But the mines of Cochabamba and Sicasica are the richest. The mountains of both these districts, especially the last, contain much ore, and numerous pieces of pure gold. Large masses are said to have been found formerly adhering to the solid rock, and still lumps weighing several ounces, are washed down by the rains. Many of the gold mines of this region have been abandoned, because it is thought they are already exhausted; but as they have been unskilfully wrought, it is still probable that, if they should ever be re-opened under better auspices, a lucrative gleaning, and even immense treasures, may be obtained from them.

Silver mines.—Helms tells us that twenty-seven mines of silver are worked in the viceroyalty. But as more than three-fourths of the produce of these mines is derived from Potosi, the mines of that mountain only deserve particular notice. The mountain of Potosi is at its base about twenty miles in circumference, and rises in a conical form to the height of 4000 feet above the surface of the circumjacent plains; it is composed chiefly of yellow coloured argillaceous slate, traversed by veins of ferruginous quartz, through which a rich silver ore is interspersed. This ore is of various colours, arising from the minerals with which it happens to be associated; it is black, brown, grey, red, or green, and is mixed with lead, iron, or copper. This rich mine is said to have been accidently discovered by Diego Hualpa, an Indian, while hunting the chamoy; in ascending the rugged steeps in pursuit of his game, he happened to pull up a shrub, and saw with surprise that it had grown in a silver soil. The discovery of the immense treasures of Potosi, though kept secret for a time, was soon after revealed to the Spaniards, and in 1545 entered in the public registers. And from that time till now, these mines have yielded a large proportion of the silver which has been imported from South America. From 1545 to 1556, no official records of their produce were kept. Ulloa conjectures, that, during these eleven years, L.144,000,000 Sterling were obtained from them. But Humboldt diminishes this enormous amount to the more credible sum of L.26,328,125; and subsequently to this period down to the year 1789, this intelligent traveller, calculating from the duties paid into the royal treasury, was enabled to exhibit a correct view of the riches obtained from these celebrated mines; which, according to his statement, amounts to the great sum total of L.318,543,935 Sterling. Helms reprobates, in severe terms, the unskilful manner in which the silver is extracted from the mines. The leaden hammer of twenty pounds weight exhausts, he says, the strength of the miner, the iron tools are of an incommodious length; and, the thick tallow candles, wrapt round with wool, vitiate the air. He also censures severely the expensive and inadequate process in use for purifying the rude ore.

Metallic iron.—A remarkable mass of native iron in the province of Tucuman has been described by travellers. It is extremely hard, but pure, ductile, and malleable, and is supposed to be about fifteen hundred weight. Conjecture has in vain laboured to account for the origin of this metallic mass. That it has been thrown from a volcano,—created on the spot where it lies,—or has fallen from the clouds,—are opinions which have been successively propagated respecting it. But now that similar masses are known to exist in other parts of the world, it is generally thought to have had a meteoric origin, and ought to be classed with those bodies which, from time to time, have fallen from the atmosphere.

Vegetables.—The influence of a genial climate upon a fertile soil, encourages in this country a profuse and vigorous vegetation; so that the astonishing variety, and the gigantic growth of the herbs, plants, and trees, which adorn and diversify the landscapes of Buenos Ayres, are scarcely equalled by those of the richest regions of the earth. The pastures, in at least three of its provinces, are of an unparalleled extent, and of unequalled luxuriance. Tobacco, cotton, maize, pepper, ginger, sarsaparilla, are indigenous to the soil. The corn, pulse, garden-herbs, and fruit trees of Europe, attain in this climate to their highest perfection, and might be extensively cultivated with certain success. Vast tracts of the country are covered with forests of everlasting verdure, among which is the lofty and elegant palm-tree, the Jesuit's bark tree, numerous dye woods, and excellent timber for all manner of useful and ornamental cabinet-work. But the tea, or herb of Paraguay, which is the most celebrated of the peculiar vegetable productions of the viceroyalty, and which in Spanish America is in great demand, is properly the foliage of a tree called Caa by the natives, resembles the orange-tree, but of larger growth, and with softer leaves, and its white flowers grow in small clusters. The mode of preparation is various. The greatest quantity is cured by laying small leafy twigs of the tree before a fire, or suspended over it, till the leaves are dried; then they are laid on the ground, and beaten with small rods, till both leaf and stalk are pulverized. This is called *Yerva de Palos.* A finer sort, called Caa miri, is made by picking out the stalks and larger fibres of the leaves, slowly roasting the soft part of the foliage, and finally beating it in a wooden mortar. In both these processes, care must be taken not to over-roast the leaves, lest they should be deprived of their gumminess and flavour. This powder is infused like tea, and drunk by all classes throughout South America. The trees from which it is prepared, and which belong to the genus *Ilex*, grow chiefly in the woods, about two hundred leagues east from Assumption, in a marshy, muddy soil.

Animals.—Zoology has been greatly enriched and extended since the discovery of the western world; and of the animals with which naturalists have thereby become acquainted, many are natives of the viceroyalty of Buenos Ayres. This is the country of the *Puma*, a beast of prey akin to the lion, but far less ferocious; the jaguar, and the cougar, which in form and habits resemble the tyger of the east; the tamandua, or ant-eater, and the sarigue, which lives on insects, eggs, and mice; foxes, wolves, and hyænas; pole-cats, martins, and ferrets, still more mischievous than those of Europe, are common. Among the animals may also be enumerated the lama, a species of camel, and equally docile and patient; the paco, highly prized for the silky fineness of its fleece, and the tapir, the American hippopotamus, or river-horse. So congenial also has this country proved to the nature of the European cow, and horse, sheep, deer, and goat, that since their introduction they have increased with such astonishing rapidity as now to traverse the face of the country with unrestrained freedom, and in countless and unclaimed myriads. Hogs, hares, and rabbits are also very numerous. Of the infinite variety of its birds, the emu, a species of ostrich, bred in the Pampas plains, and the condor, the most formidable of the vulture race, are the most peculiar to the climate. Turtles, seals, and sea-lions frequent the shores of the ocean; alligators of large size, and an infinite variety of fishes, inhabit the rivers; serpents, among which is the enormous boa constrictor, and an endless variety of insects and reptiles swarm throughout the country, though chiefly in the forests, and among the marshes.

Population.—The population of Buenos Ayres has been variously stated. Some have computed the amount of Spaniards and Creoles, exclusive of Indians, at one million; but according to Humboldt, the whole is about 1,100,000, although he thinks the estimate is not very correct. The inhabitants are divided into four classes, the European Spaniards, and the Creoles, or Spaniards born in America; the Mulattoes and Mestizos, or people of colour; the negroes or Africans; and the Indians, or original inhabitants of the country. The European Spaniards hold the first rank, fill the chief offices of trust, and are the most industrious and wealthiest part of the community. Many of the Creoles are those descended from native Spaniards, possess valuable estates, which they inherit from their forefathers; but they are, in general, an indolent and luxurious race, averse to all habits of mental exertion or active industry.

The Mulattoes and Mestizos, of which the former is the offspring of a white and a negro, and the latter of a white and an Indian, form a very useful class of the population, and are chiefly employed in the mechanic arts, retail trades, and other active labours, which the pride or indolence of those of the higher classes precludes them from undertaking. The third class of inhabitants consists of negroes who have been imported from Africa, and are in a state of slavery. Many of them are employed in the household and domestic establishments of the Spaniards; and it is said, that those who are doomed to labours of a severer kind, experience kinder and more humane treatment than the same unfortunate race in some other American colonies. The Indians constitute the fourth class of the inhabitants, who, from the first invasion of the Spaniards down to the present time, have been subjected by their cruel taskmasters to severe bondage and great oppressions. These cruelties and severities, indeed, at one time threatening to exterminate the whole population, called for the interference of the Spanish court, by whom many laws and regulations were made, to prevent the evils to which the poor natives were exposed, and to protect them against the violence of those who inflicted them; and in many respects, it is said, the condition of the Indians is greatly improved; but still they are liable to oppressive tyranny and arbitrary exactions, for they are compelled to certain kinds of labour, as in the erection of public buildings, making roads, and working mines. Many of the Indian tribes have never been brought under subjection to the Spaniards. Some of them are of a warlike character, and live chiefly by plunder; others are engaged in agriculture, and have some intercourse with the Spanish settlements, bartering the productions of their country for European commodities.

Commerce.—Beside the precious metals, hides, tallow, wool, furs, wood, and drugs, particularly Jesuits bark, form part of the exports to the mother-country; in return for which, they receive those productions of European industry which are necessary for the supply of the colony. The trade between Buenos Ayres and the western regions of South America, as Peru, Chili, and Lima, is also considerable, as well as with the Havannah, and the coast of Africa.

Civil establishment.—The viceroy is the representative of the Spanish monarch, has all the power and dignity of a sovereign prince, and exercises the supreme authority in all departments of the state. The nomination of the viceroy is generally for three years; but the period of his government is sometimes extended, if he happen to command influence at the Spanish court; and although the legal salary is not large, yet opportunities are not wanting, if he have the inclination, to accumulate, in a very short time, an immense fortune. To the royal audiences of Buenos Ayres and Los Charcos, the cognisance of all civil and criminal causes is committed; and in actions not exceeding 10,000 piastres in value, their sentence is final; but in causes concerning property of large amount, an appeal may be carried before the royal council of the Indies in Spain. The same tribunals possess the privilege of remonstrating against the political regulations of the viceroy, which regard questions of civil right, and of laying the matter before the council of the Indies. To each province is appointed a governor, who is under the jurisdiction of the viceroy; and subordinate to the governors are numerous orders and denominations of magistrates. The jealousy of the mother-country of her American colonies, and her anxious endeavours to prevent fraud in remote provinces, have greatly encumbered every department of domestic police and finance with numerous tribunals and officers. The ecclesiastical establishment of Buenos Ayres is kept up with great splendour.

Discovery and conquest.—Brazil was accidentally discovered by the Portuguese in 1500; in the succeeding year Americus Vespucius sailed as far south as the 52° of latitude; but the severe weather compelled him to return to Europe without making any important discovery; and in 1516, Dias De Solis, a Spanish navigator, entered the Rio de la Plata, and sailed along its northern shore; but having incautiously landed, was massacred by the Indians. Another Spanish navigator, Sebastian Cabot, was commissioned by Charles V. to sail round the world; and in the progress of his voyage he anchored in Rio de Solis, the name which it then bore; he proceeded far into the interior, and built a fort on the Parana; and seeing the natives have ornaments of gold and silver, he changed the name of the river to Rio de la Plata, or River of Silver. Cabot dispatched a ship to Spain, where the news of his discoveries were received with great satisfaction, and an armament for the conquest of the country was ordered to be fitted out. But disappointed of reinforcements for two years, he returned to Spain, and left a garrison of more than one hundred men in the fort, which was soon after attacked, and the whole of the Spaniards were massacred. Another armament under Pedro de Mendoza, arrived in South America in 1535, and founded the city of Buenos Ayres on the south bank of the river. After various struggles with the Indians, he and his successors extended their conquests, established new colonies, and built cities. The Jesuits made their appearance in this part of South America about the end of the 16th century, and were highly instrumental, by their address and perseverance, in conciliating the Indians, whom they were afterwards permitted to collect together into townships independent of the Spanish

Buenos Ayres.

establishments, and only acknowledging the sovereignty of the king of Spain. To protect themselves against violence, they were empowered to embody and arm their Indian converts in the European manner.

A settlement on the north bank of the Rio de la Plata, which was planned and attempted by the Portuguese, excited the jealousy of the Spaniards, and produced many disputes and struggles, until it was finally ceded in 1778 to the latter. But the prosperity and growing power of the Jesuits at last attracted the attention of the court of Spain, and the revolt of some of those tribes which had been under their authority greatly diminished their influence; for it had been alleged that the Jesuits had encouraged and aided the opposition of these tribes to the dominion of Portugal, to whom they had been assigned by a treaty between Spain and that power. The expulsion of the Jesuits from Spain in 1767 was naturally followed by the loss of their influence in the New World.

An expedition, fitted out by the British, under general Beresford and Sir Home Popham, arrived in June 1806, and, after a slight opposition, entered Buenos Ayres, and obtained a rich booty in specie and colonial produce; but the Spaniards having collected reinforcements, retook the city in August following; and the strong post of Maldonado, at the mouth of the La Plata, was all that remained in possession of the British force. With the hope of being able to secure a wide field of commercial intercourse, a strong reinforcement was dispatched from this country, and Monte Video was taken by storm; and for the reduction of Buenos Ayres, another expedition, under general Whitelocke, arrived at Monte Video in May 1807, and soon after proceeded against the capital. But the unfortunate issue of that attempt, through the misconduct of the commander, who was cashiered by the sentence of a court-martial, disappointed the hopes of the country, and finally terminated in an armistice and convention, in which it was agreed that the British should evacuate the Rio de la Plata.

The distractions which prevailed in the mother-country extended their influence to this valuable colony. Anxious to extend and establish his authority, Bonaparte had sent emissaries throughout the American colonies; but a revolution took place in the government of the settlement in 1810; a junta was appointed in Buenos Ayres, and Ferdinand VII. was acknowledged. The regency of Spain appointed a viceroy; and when he arrived to take possession of the government, the junta refused to submit to his authority, and seemed disposed to throw off their dependence on the mother-country until Ferdinand should be restored. But the viceroy succeeded in gaining a party in Monte Video to second his views, and the inhabitants of that town declared for the regency. To compel the junta of Buenos Ayres to the same submission, hostilities commenced; and although an accommodation was attempted, and in some degree succeeded at the time, the scanty resources of the feeble power of the parent state may not soon be able to recover its lost authority.

BUENOS AYRES, the capital of the viceroyalty of the same name in South America, stands on the south bank of the Rio de la Plata; became the principal town of the province in 1620, and greatly increased in wealth and population, when it was made the seat of the vice-regal government in 1778. It is regularly built; the houses are chiefly of brick; the chief streets are spacious and elegant; and the principal square has the fort, which includes the viceroy's palace and a royal chapel on one side, the town hall on the opposite side, and the cathedral, a magnificent structure, on the west side. Four monasteries, several hospitals and churches, some of which are not destitute of elegance, are also enumerated among the public buildings. Many of the houses are surrounded with gardens, and are fitted with balconies and lattice works, for the reception of ornamental shrubs and flowers. The suburbs, occupied by negroes and mestizos, are not remarkable for cleanliness. For several leagues in the vicinity of the city, the country is well cultivated, and presents a rich and diversified scene of gardens and corn-fields; and the immense plains which succeed afford pasture to great numbers of wild horses, and large herds of cattle.

The population of Buenos Ayres has been variously stated at 30,000, 40,000, and even as high as 70,000. The trade in which they are engaged has been already alluded to in the account of the viceroyalty. It is subject to much inconvenience from the difficult navigation of the La Plata, and the want of a commodious harbour near the town. No vessels of large burden can approach nearer than the bay of Barragan, which is seven leagues distant. To obviate these inconveniences, Monte Video was established, and this spot was selected on account of its safe and excellent harbour. S. Lat. 34. 36. W. Long. 58. 31.

Buffon.

BUFFON, George Louis le Clerc, Count of, a celebrated French naturalist, was born at Montbard in Burgundy, in 1707, and being destined for the profession of the law, commenced his studies at the college of Dijon; but the mathematical sciences early occupied his attention, to the exclusion of other pursuits. While in his 20th year, he became acquainted with an English nobleman, whom he visited in England, and afterwards accompanied to Italy, where the grand scenes of nature attracted more of his attention and admiration than the most exquisite productions of art.

Succeeding to the ample fortune of his mother, he was raised to that state of affluence and independence which enabled him to pursue, without interruption, those studies to which his future life was devoted. Among his first works presented to the public, were translations of Hales' Vegetable Statics, and Newton's Fluxions, the prefaces of which are distinguished by that splendour of language which formed one of the chief features of his subsequent writings. Some curious experiments on the strength of wood, and the construction of a powerful burning mirror, are also enumerated among the early labours of this philosopher in the physical sciences.

The appointment of M. Buffon, in 1739, to the place of intendant of the royal garden and cabinet, fixed his resolution of devoting himself entirely to the study of natural history; and the first fruits of

Buffon.

his labours on this subject appeared in 1744, under the title of a Theory of the Earth, which afterwards formed a part of his larger work. The first volume of his Natural History was published in 1749, and was completed at different intervals in fifteen quarto volumes. But in the composition of this work, although a large portion of it is the production of his own genius and industry, he received material assistance from others, and particularly from M. de Monbelliard and the abbé Bexon; and the anatomical description of animals is the work of Daubenton.

Scarcely any thing connected with this eminent naturalist can be deemed unworthy of record, but his method of study and distribution of his time cannot fail to be received with interest. His industry and application were so great that he devoted 14 hours daily to literary labour; he rose early in the morning, usually about five; and even in his younger years, when he did not return from evening parties at Paris till two o'clock in the morning, his servant had express orders not to permit him to remain in bed after that hour. The regulation of his domestic affairs, and the writing of letters, were the first objects of his attention; and when this business was completed, he retired to his studies about six o'clock, in the pavilion called the tower of St Louis, which was erected at the end of his garden, and about a furlong distant from the house. The interior of this mansion, on account of its lofty roof, presented the appearance of a chapel; no books or pictures were to be seen, and an armed chair, and a large wooden escrutoire, were its only pieces of furniture. Within this was another apartment, a small square building, which was adorned with drawings of birds, and other animals, and was the residence of the naturalist during great part of the year. He breakfasted in the pavilion, and this meal consisted of a piece of bread and two glasses of wine, and then indulged himself in an hour's rest. Having resumed his labours, he continued for two hours after breakfast, and then returned to his house. He spent a considerable portion of time at dinner, slept an hour after it, and, after a solitary walk, enjoyed the conversation of his family or guests during the rest of the evening, and about nine o'clock went to bed. Such was the routine of life which he pursued during the long period of fifty years. With a vigorous constitution, he enjoyed excellent health to a late period of life; but in his old age he was often subjected to the most excruciating agony from fits of the stone. He died in the 81st year of his age, and in the month of April 1788. His funeral was attended by a numerous concourse of persons of rank and literary distinction; and it is said that there were not fewer than 20,000 spectators, through which the procession passed. The monument erected to his memory was destroyed during the blind fury of revolutionary frenzy; the leaden coffin in which he was deposited was carried off, and his remains were left exposed to public view. A proposal that his ashes should be consigned to repose in the Pantheon, was rejected by the barbarians of that time as a profanation.

Buffon possessed a commanding figure, his manner was dignified, and his countenance expressive of superior intelligence. He was fond of luxury and magnificence, vain of his talents and writings, and was not scrupulous in bestowing on them his own commendation. His moral and religious character has been properly a subject of censure and regret; but the splendid style of his compositions can never fail to be a subject of admiration.

Buffon left one son, who fell a victim, in 1795, to the revolutionary tribunal.

BUKHARIA, an extensive region of Asia, which is divided into Great and Little. See BUCHARIA.

Bulama.

BULAMA, an island belonging to the Bijuga cluster of islands at the mouth of the Rio Grande, on the western coast of Africa; lies in latitude 11° 8′, and west longitude 14° 50′; is separated from the main land by a channel two miles broad, which forms a good harbour, and is about 20 miles in length, and from 8 to 15 in breadth. The ascent from the sea-shore is gradual, till it terminate in some mountains of considerable elevation in the centre of the island. It is watered by several fine streams, and the soil is remarkable for its fertility. In many places it is clothed with lofty trees; cotton, indigo, coffee, and rice, are enumerated among its indigenous productions; all the rich fruits of tropical regions grow in great profusion; and, from the rich soil and favourable climate, the culture of sugar and tobacco might be highly advantageous. Wild horses and cattle abound in the extensive savannahs; stags, goats, buffaloes, and elephants, are common; doves, guinea-fowls, and other birds of beautiful plumage, appear in great flocks; and the surrounding sea affords plenty of excellent turtle and great variety of fish. The climate, at least to those who have attempted settlements in this island, is far from being salubrious; the rainy season commences in June and terminates in October, and its approach is generally preceded by tornadoes; but they are neither so violent nor so destructive as the hurricanes of the West Indies.

The peculiar position and productions of Bulama, render it a favourable place for a commercial settlement, and with this view it has often attracted the attention of Europeans. When it was visited by the French, in 1669, it had no permanent inhabitants. The Bijugas, a warlike people, who had expelled, after a long and bloody struggle, the Biafaras, the original possessors, only made an annual visit, for the purpose of hunting the elephant and other animals. The French several times projected the establishment of a colony, but the proposal was never executed. In 1792 an attempt was made to establish a colony from England on this island, and the object of those who entered into the scheme was to open up a commercial intercourse with that part of Africa, and to promote the civilization of the inhabitants. The expedition, consisting of three vessels, with 280 souls, men, women, and children on board, arrived at the island in the month of May; the command of the whole was intrusted to captain Dalrymple and a council of 12, who were chiefly officers of the navy, and among them was captain Beaver, who afterwards published the history of the colony. But the settlers meeting with unexpected difficulties, soon became dissatisfied, and a sudden attack of the natives, by which several of the English settlers were killed, threw them into such dejection, that they never recovered from its effects. Part of the colonists left the settlement, and proceeded in one of the ships to Sierra Leone, with the view of returning to England. The remainder, not more than one-third of the original number, placed themselves under captain Beaver, who was determined to remain in the island; but although his prudence, activity, and perseverance in this arduous task have never been surpassed, yet the difficulties with which they had to struggle, and the sickness and disaffection which prevailed, and by desertion or death daily diminished their numbers, produced such despondency, that they determined to return home, and left the island in the end of November 1793; and thus was the benevolent purpose of the association completely frustrated. For a very interesting account of this establishment, see Beaver's *African Memoranda.*

BULB, in certain tribes of plants, is the hybernaculum, or winter residence of the embryo of the future leaves and flower. The bulb is properly considered as analagous to the bud in other kinds of plants, with this difference, that the latter is formed on the stem or branches, but the former is produced under ground. Those who are curious to see the structure of the bulb, may examine that of the tulip, and, by carefully separating the parts, may be gratified with discovering the flower in miniature, but distinctly formed, in the centre and lower part of the bulb, from which the roots proceed.

BULGARIA, Great, a province of Tartary, which forms part of the government of Caucasus, and is subject to Russia; is bounded on the north by the kingdom of Cassan, by Baskiria on the east, the river Samara, which separates it from Astrakan, on the south, and on the west by the Volga. The name is derived from Bulgar, the capital, which is situated near the Volga, and is now reduced to about 100 houses occupied by peasants. Many rivers traverse the province, and discharge their waters into the Volga; and it is said that the mountains abound with valuable minerals.

BULGARIA, Little, a province of the Turkish empire; is bounded on the west by Servia, by the Danube on the north, the Black sea, on the east, and by mount Haemus on the south, by which it is separated from Macedonia and Romania. This province forms part of ancient Mysia, which was overrun by the barbarous tribes from the banks of the Volga, about the close of the seventh century, and from them it received its present name, and rose to the rank of a kingdom. The Romans maintained almost a perpetual struggle with these invaders for several centuries; they became at last subject to the Roman emperors, and for nearly two centuries continued under their authority. But on the decline of the eastern empire they threw off the yoke, and resumed their independence. In the 13th century, being defeated by the king of Hungary, they acknowledged him as their sovereign; and, in the end of the 14th century, they were finally vanquished by Bajazet, and their whole territory was reduced to the state of a Turkish province.

The general aspect of the province is mountainous, but some of the plains and valleys, which are well watered by numerous streams, are remarkable for fertility. Grain of every kind, cattle, horses, wool, silk, hides, iron, wine, wax, tobacco, and the manufacture of morocco-leather, are enumerated as the chief productions of Bulgaria, and furnish the means of a profitable commerce, by means of the navigation of the Danube and the ports on the Black sea. The inhabitants of this province are Christians of the Greek church.

BULL, from the word Bulla, which signifies a seal, is a decree issued by the pope, is analogous to the edicts of temporal princes, and is employed both in matters of justice and of grace. The bull is written in an old gothic character on parchment, and the leaden seal appended to it represents on one side the figures of Peter and Paul, with a cross in the centre, and on the reverse the name of the pope and the year of his pontificate. If the apostolical letter refer to matters of justice, the seal is attached by a hempen cord, but in affairs of grace is suspended by a silken thread. Bulls are granted for the consecration of bishops, the promotion to benefices, and the celebration of jubilees. The bull which is read every year, on Maunday-Thursday, or the day of the Lord's supper, in the pope's presence, contains execrations against heretics, and all who disturb or oppose the authority of the holy see; and, to denote the thunder of this anathema, the pope, after the reading is concluded, throws a flaming torch on the ground.

An edict issued by the emperor Charles IV. in 1356, and which is regarded as the fundamental law of the German empire, is called the *golden bull*, because the seal is of gold. It contains thirty articles, which fix the number, and regulate the functions, rights, and privileges of the electors. The original, which is written in the Latin language on vellum, is preserved at Frankfort. The *Caroline* bull, issued in 1359 by the same emperor, cancels all regulations to the prejudice of the clergy, made either by himself or by any of his predecessors.

BULLA, the Dipper, a genus of shell-fish belonging to the order Univalves, and of which several species are natives of Britain. See Conchology.

BULL-FIGHTING, is a kind of entertainment which has been common in many nations, and particularly among the Spaniards at the present day. Bull-fighting was practised among the Greeks; but it is doubted whether it was known among the Romans, who were familiar with combats of wild beasts. The Spaniards derived it from the Moors, among whom it was celebrated with great splendour and ceremony. The practice has been prohibited by some popes; but the attachment to this sport has been too strong to eradicate it entirely, and therefore it has been permitted by royal and ecclesiastical authority.

The pomp, the ceremonies, and the danger which attended these exhibitions are finely delineated by Mr Gibbon, in the description of a bull-fight in the *Colisæum* at Rome, in the year 1332, and which he has quoted from Muratori. "A general proclamation as far as Rimini and Ravenna invited the nobles to exercise their skill and courage in this perilous adventure. The Roman ladies were marshalled in three squadrons, and seated in three balconies, which on this day, the 3d of September, were lined with

Bull-fighting scarlet cloth. The fair Jacova di Rovere led the matrons from beyond the Tiber, a pure and native race, who still represent the features and character of antiquity. The remainder of the city was divided between the Colonna and Ursini families: The two factions were proud of the number and beauty of their female bands; the charms of Savella Ursini are mentioned with praise; and the Colonna regretted the absence of the youngest of their house, who had sprained her ancle in the garden of Nero's tower. The lots of the champions were drawn by an old and respectable citizen; and they descended into the arena or pit to encounter the wild bulls on foot, as it should seem, with a single spear. Amidst the crowd our annalist has selected the names, colours, and devices of some of the most conspicuous knights, and several of the names are the most illustrious of Rome and the ecclesiastical state. The colours were adapted to their taste and situation; and the devices are expressive of hope or despair, and breathe the spirit of gallantry and arms. 'I am alone like the youngest of the Horatii,' the confidence of an intrepid stranger; 'I live disconsolate,' a weeping widower; 'I burn under the ashes,' a discreet lover; 'I adore Lavinia or Lucretia,' the ambiguous declaration of a modern passion; 'My faith is as pure,' the motto of a white livery; 'Who is stronger than myself,' of a lion's hide; 'If I am drowned in blood what a pleasant death,' the wish of ferocious courage. The pride or prudence of the Ursini restrained them from the field, which was occupied by three of their hereditary rivals, whose inscriptions denoted the lofty greatness of the Colonna name: 'Though sad I am strong;' 'Strong as I am great;' 'If I fall, (addressing himself to the spectators,) you fall with me;' intimating, says the writer, that while the other families were the subjects of the Vatican, they alone were the supporters of the Capitol. The combats of the amphitheatre were dangerous and bloody. Every champion successively encountered a wild bull; and the victory may be ascribed to the quadruped, since no more than eleven were left on the field, with the loss of nine wounded and eighteen killed on the side of their adversaries. Some of the noblest families might mourn; but the pomp of the funerals in the churches of St John Lateran, and Santa Maria Maggiore, afforded a second holiday to the people. Doubtless it was not in such conflicts that the blood of the Romans should have been shed; yet, in blaming their rashness we are compelled to applaud their gallantry; and the noble volunteers who displayed their magnificence and risked their lives under the balconies of the fair, excite a more generous sympathy than the thousands of captives and malefactors who were reluctantly dragged to the scene of slaughter."

The excessive fondness of the Spaniards for bull-fights is a remarkable feature in their manners, and is hostile to the feelings of other European nations, who are less familiar with such sights. The Spaniards themselves regard this practice as the means of preserving energy of character, and of habituating them to strong emotions, which are only terrible to timid minds. In these sentiments the Spaniards are not singular, for it may be recollected that an enlightened legislator, the late Mr Windham, attempted to defend on the same principles the equally cruel sport of bull-beating in England, when a proposal was made for a legal enactment to suppress that barbarous practice. But although bull-fighting was formerly reckoned among the royal festivals in Spain, attempts have been made, if not entirely to abolish the entertainment, at least to diminish the number of the exhibitions. Bull-fighting

These bull-fights are attended with very considerable expence, but they are also profitable to the undertakers, for the spectators pay for admission as to any other spectacle, and the price of the best and most commodious seats is as high as a dollar. The profits which remain after defraying the expence of the horses and bulls, and the wages of the *torreadores* or combatants, are destined to charitable purposes. In some cities the principal square is fitted up as a kind of theatre for this exhibition.

The spectacle begins with a kind of procession round the square, in which the combatants, either on foot or on horseback, make their appearance; after them two officers of justice in black robes, and of a grave deportment, advance to the president of the spectacle, and request to have an order for the entertainment to commence. A signal is then given, and the animal, which had been previously shut up in a cabin, with a door opening to the square, rushes forward, and is received by the spectators with the loudest acclamations. The *picadores*, or combatants, on horseback, dressed in the ancient Spanish manner, and armed with a long lance, begin the contest; and if the bull, without provocation, dart upon them, a favourable opinion is entertained of his courage; and if, after being wounded and repulsed, he return to the charge, the most enthusiastic expressions of joy are heard; but if he is struck with terror, and seem anxious to avoid his antagonists, he is hooted and hissed by all the spectators, and loaded with reproaches and blows by those who are near him. If after all this his courage cannot be roused, large dogs are let loose against him, and after being torn and mangled, in the estimation of the Spaniards he perishes ignobly. The most animated, as well as the most bloody scene, is exhibited with the combatant on horseback, for the irritated and wounded animal sometimes attacks and overturns both horse and rider; and when the latter is dismounted and disarmed he is protected from immediate danger by the combatants on foot, who endeavour to provoke and divert the bull's attention by shaking before him pieces of cloth of different colours, but in attempting to save the dismounted horseman, they are themselves exposed to great hazard; for the bull sometimes pursues them, when they escape by dropping a piece of coloured stuff, against which the deceived animal exerts all his rage, or, if this resource fail, the combatant springs over a barrier six feet high, which incloses the inner part of the arena. In some places this barrier is double, forming in the intermediate space a circular gallery, behind which the combatant is in safety, but in some cases the barrier is single, and the bull succeeds in his attempt to surmount it, when an indescribable scene of consternation and confusion immediately follows, which proves fatal to many of the spectators, while the unfortunate animal falls under the blows which are levelled at him from all sides.

If the animal is not dispatched by those on horseback, and if he seem disposed to renew the combat, they retire and give place to the *banderilleros*, who are on foot, and presenting themselves before the animal, the moment he darts upon them, plunge into his neck a kind of hook-darts, ornamented with small streamers of coloured paper. The rage of the animal is raised to the highest pitch, and, were it not for the experience and skill of the assailants, his furious efforts would hurl destruction on their heads in a moment. The bull being exhausted with numerous wounds and loss of blood, another victim of barbarous sport is demanded; the signal of death is given by the president, and announced by the sound of trumpets. The matador then appears in the arena, when the other combatants retire. In one hand he holds a long dagger, and with the other waves a flag before his adversary. The interest and pleasure of the spectators, which had been suspended, are again awakened, and the matador, watching the favourable opportunity, inflicts the mortal blow; and if the animal fall, the loudest shouts of acclamation announce the triumph of the conqueror; but if he fail in the first attempt, a murmur of disapprobation pervades the assembly. The fallen animal is then dragged from the arena by three mules ornamented with bells and streamers, and another is immediately introduced to run the same course of barbarous torment. At one period six bulls were thus sacrificed in a morning, and twelve in the afternoon, on the days appropriated to these entertainments in Madrid.

BULLION, is generally defined gold or silver in the mass, or in an uncoined and unwrought state. The same word is used to express these metals in their unalloyed or virgin state; is sometimes applied in a more general sense to gold and silver with every proportion of alloy, and in the British market is understood to be of the British standard; and as gold is the standard metal, the word bullion without addition, refers to gold bullion. According to the British standard, the proportions in a pound of gold are 11 ounces 2 pennyweights of pure metal, and 18 pennyweights of alloy. The exportation of British coin is forbidden by law; but no restrictions are imposed on the trade in foreign coin or bullion. Connected with the suspension of cash payments by the Bank of England, the extensive circulation of paper money, the varying price of bullion in the home and foreign market, and the effect of all these circumstances on the commerce of Britain, no topic has furnished matter for more elaborate parliamentary discussion, or has been the subject of a greater number of pamphlets of different kinds from those who have espoused different sides of the question; and, after all, it must appear obvious, from the very opposite sentiments which have been maintained, that it is not yet well understood, if a subject of so complicated a nature be capable of full and satisfactory elucidation. But to the pamphlets already alluded to, and to the proceedings in parliament, we refer those who wish to render themselves familiar with this intricate subject of political economy.

BUNDELCUND, a spacious district in the province of Allahabad in India, lying between the 24° and 26° of north latitude, and supposed to include 11,000 square miles. The country is high and mountainous, and but imperfectly cultivated. The summits of the hills are chiefly rocky, but they are covered with small copsewood; for timber-trees of a large size are rare. The soil, though not generally, is rich, and produces a number of teak trees, but they are not of a very vigorous growth. Within this district are some diamond mines of great antiquity, and at one time very valuable; but they are now less productive. This territory has been subject to various revolutions, both between its native princes and their neighbours, and the British power in India, and finally, in 1804, became a British district, subordinate to the Benares circuit, and having a civil establishment for the administration of justice and the collection of the revenue appropriated to itself.

BUNYAN, John, the celebrated author of the *Pilgrim's Progress*, was a native of Bedfordshire in England, and was born in the year 1628. Although in the humble situation of a tinker, and perhaps connected with the tribe of gypsies, his father had him taught to read and write; but the son, influenced by evil example, very early indulged in vicious courses, and while yet young, was notorious for every kind of profligacy; but at last he began to reflect seriously on his wicked life, and, with the aid of a powerful imagination, he conceived that he heard a warning voice from heaven declaring his guilt. From this time he reformed his conduct, and having joined a congregation of Baptists at Bedford, became a zealous convert to the profession and practice of religion. He then became the object of severe persecution, was brought to trial for attending conventicles, and condemned to perpetual banishment; and although this sentence was not executed, the unfortunate Bunyan spent the long period of $12\frac{1}{2}$ years in prison; and obtained his enlargement through the kind interference of Dr Barlow, bishop of Lincoln. It would appear that he had delivered religious instruction to a number of dissenters, who were confined in the same prison with himself; and in the last year of his imprisonment he was chosen pastor of the congregation at Bedford. A meeting-house was afterwards built for him, where he preached to crowded audiences. He died in London in 1688, in the 60th year of his age.

No work in the English language has ever obtained a greater share of popularity than the *Pilgrim's Progress*. It is in the form of an allegory, and not more distinguished by its practical utility than by the poetic fancy which it displays in the delineation of striking pictures of life and manners. This work has been translated into most European languages. The *Holy War* is another allegory by the same author; and his whole works have been collected in two vols. folio, embellished with plates, with a recommendatory preface by the celebrated George Whitefield.

BUONAROTTI, Michael Angelo, a celebrated painter, sculptor, and architect, was born in 1474, at Castel Caprese in Tuscany, a fortress in the state of Florence, where his father was governor. His earliest years indicated the tendency of his genius, for when at school he devoted so much time to drawing, Burdor. that other studies were neglected. With no small reluctance his relations yielded to the bent of his inclination, and, although degrading to the dignity of his family, he was permitted to study painting as a profession, and, at the age of fourteen, he was placed as a pupil under Dominico Ghirlandaio, an artist of some eminence. As a proof of the talents of Michael Angelo, it was stipulated, it is said, that the master should pay him an annual salary, instead of receiving a premium from the pupil, as was usual in such cases. About this time the fine arts began to revive in Italy, under the liberal patronage of the munificent family of Medici. The rising genius of Michael Angelo attracted the notice of Lorenzo de Medici, and procured for him a large share of the countenance and friendship of that distinguished prince. Admitted into his house at the early age of fifteen, he enjoyed the high advantage of conversing with men of learning and genius, and of improving his taste by studying the invaluable collections of art at Florence. After the death of Lorenzo, which happened two years after Michael Angelo was received under his roof, the artist remained for some time in the employment of his less worthy and less respected successor, and during this period he executed several works of sculpture.

Bologna, Florence, and Rome, became at different periods the future residence of this extraordinary artist, and still retain splendid examples of his unrivalled productions. Of the efforts of his genius in sculpture, the colossal statue of David, and still more so the statue of Moses, are always noticed and universally admired; the Sistine chapel at Rome, the ceiling of which he adorned with paintings, it is said in the short period of twenty months, and particularly the celebrated picture of the *Last Judgment* in the façade of the same chapel, which was executed at a subsequent period, bear ample evidence of the powers of his pencil, and the promptitude and facility of his execution. The paintings now alluded to are executed in distemper, and doubts are entertained whether at any time he practised oil painting. Of his powers as an architect, the church of St Peter's at Rome exhibits the noblest monument. This splendid structure, begun in 1506, had been under the direction of different artists, who in the progress of the work had deviated from the original plan according to their own views, and had left it an unsightly and discordant pile, when the comprehensive genius of Michael Angelo threw the magic charm of simplicity and harmony over the whole.

In all the departments of art to which Michael Angelo directed the various powers of his mind, he has displayed an originality, energy, and sublimity of conception, which have been rarely equalled, and never surpassed. The peculiarity of his style consists in grandeur and majesty; and to all his characters he has given a kind of elevation above common nature, and a more perfect form than appears in real life. Having reached the venerable age of 90, he died in the year 1563.

BURFORD, a market-town of Oxfordshire in England, stands on a gentle ascent near the river Windrush, and is supposed to be one of the oldest towns of the kingdom of Mercia. The number of inhabitants exceeds 1500, and they are employed in the manufacture of rugs and duffles, but particularly in making saddles, for which this place has been long celebrated. The weekly market is well supplied with grain and cattle, and the horse races on the neighbouring downs attract a great deal of company from Oxford and the surrounding country.

Burger. BURGAGE-TENURE, or tenure in burgage, is when the king or other person is lord of an ancient borough in which the tenements are held by a certain established rent. Boroughs possessing this privilege seem to have undergone no change after the Norman invasion, and therefore this manner of holding is traced to the times of the Saxons; and hence, it is supposed, have arisen the various customs by which property is held under this tenure, and which are most strictly of a feudal nature. In England, 29 boroughs hold by burgage-tenure, and every individual proprietor of a house or tenement possesses the right of voting for burgesses to serve in parliament; and in some of these boroughs the widow has right, by privilege of this tenure, to be endowed not only in a *third*, according to common law, but in the whole of her husband's tenements.

BURGER, Godfrey Augustus, a German poet, was a native of the principality of Halberstadt, and was born in January 1748; shewed no great inclination to serious study till he began to read the Bible, the sentiments and language of which inspired him with enthusiasm, and led him to the first attempts at versification, which were imitations of the psalms. At this time he had scarcely completed his tenth year. Under the tuition of his father, whether it proceeded from a froward and idle disposition, or from want of capacity, he made little progress in the Latin language. In his 12th year he was placed with his grandfather, to afford him an opportunity of attending a public grammar school; but on account of some satirical verses on a schoolfellow, he was removed to Halle in 1762, and two years afterwards he entered into the university of the same place, for the purpose of studying divinity; but the clerical profession, to which he was destined, was ill suited to the dissipated habits which he had acquired. His studies were now directed to jurisprudence, and for this purpose he repaired to Gottingen, where his habits were not improved; but with the assistance of some men of genius, who became his associates and friends, he was enabled to proceed in the more agreeable pursuits of literature and poetry. About the year 1770, Burger began to be known as a poet, in the contributions which he made to the first German poetical almanack, and about the same time he composed his *Ode to Hope*, and the translation of the Vigil of Venus. He retained for some time the office of a magistrate in the neighbourhood of Gottingen; he had also married during this period; but the situation was neither congenial to his disposition, nor the emoluments which it afforded equal to his expensive habits. Returning to Gottingen in 1784, after resigning his office, and labouring under pecuniary embarrassments, he resolved to devote himself entirely to literary pursuits; and aspiring to a professorship, he began to read lectures on belles lettres and philosophy. The death of his second wife, who was the youngest sister of his first wife, and who lived only a few months after the marriage, was a severe affliction to the poet; and from this time, bodily disease and mental distress rendered his future life a scene of poverty and melancholy. A third marriage, the consequence of a romantic attachment, added nothing to his happiness, but in the end was the source of great misery, and was followed by a divorce. After a lingering illness, and being subjected to many severe privations, he died at the early age of 47, in June 1794.

The life of Burger exhibits another example which, it is to be regretted, is not rare in the records of biography, of irregular conduct and depraved habits associated with powerful genius. The works of Burger are characterized by vigour and originality of invention, richness of imagery, energy of language, and harmony of versification. In the composition of his ballads he is peculiarly distinguished. The English reader is familiar with the romantic ballad of *Leonora*, in the translations of Pye, Spencer, Scott, and others, as well as with the *Parson's Daughter Betrayed*, and the *Inhuman Huntsman*, of which also translations have appeared; all of which exhibiting simplicity, pathos, and energy, have acquired great popularity.

BURGESS, in its more general acceptation, is an inhabitant of a borough; but in a more restricted sense, it is applied to the freemen of the borough who have certain privileges of trade, or of practising some mechanical art. The same word is used for the representative of a borough town in parliament, because they are supposed to represent the mercantile or trading interest of the nation.

BURGLARY, or nocturnal house-breaking, by the old English law called *hamesucken*, a word still in use in the law of Scotland, has been always regarded as a crime of the highest nature, and subjected to the severest punishment. The characters which lawyers have given of a burglary are, that it must be committed by night; and, secondly, in a mansion-house; thirdly, by breaking and entering into it; and, fourthly, with a felonious intent. Burglary is a felony in common law, but within the benefit of clergy; and when it is committed in any house belonging to the Plate-glass Company, with intent to steal the stock or utensils, it is declared by statute to be single felony, and punished with transportation for seven years.

BURGOS, an ancient city of Spain, the capital of Old Castile; stands on the declivity of a hill on the bank of the river Arlanzon, and is irregularly built, and surrounded by high walls, which are washed by the waters of the river. The streets are narrow and crooked; but the principal square in the middle of the city is surrounded by piazzas, supported by lofty pillars, and adorned with fine houses. The principal public buildings are, the Hotel de Ville, the palace of Vilaseo, the triumphal Arch erected in honour of the first count of Castile, and particularly the cathedral church, which is regarded as one of the most splendid specimens of Gothic architecture in Spain. This noble edifice, which was begun in the 13th century, is richly embellished with towers, columns, and statues, executed with exquisite delicacy, and all in the finest and best preservation. Some of the chapels are adorned with beautiful paintings by Raphael and Michael Angelo. Some of the other churches are also magnificent structures; as well as some of the convents and hospitals, which are well endowed. A college for the education of youth, and an academy for the polite arts, have been long established, and a school of surgery was instituted in the year 1800.

The population of Burgos is estimated at 9,000; but when it was the seat of royalty it could boast of 40,000 inhabitants, and then its commerce and manufactures were in the most flourishing state. The seat of government was transferred by Charles V. from this place to Madrid, about the beginning of the 17th century. Cloth and fine woollen stockings are now the chief manufactures, and the exportation of the woollen cloths of Castile constitute its only trade. Burgos is 112 miles north from Madrid.

BURGUNDY, a district of France, formerly under the denomination of a province or government, but now divided into the departments of Cote d'Or, Saone, Loire, and Yonne. This district is supposed to have derived its name from the Burgundians, a German nation, by whom it was first established about the commencement of the 5th century. In the progress of its history, it acquired great influence among the states of Europe; and some of its sovereigns, the dukes of Burgundy, were elevated to the throne of France.

The province, between 40 and 50 leagues in length, and about 30 in breadth, is traversed by a mountainous ridge, which extends from Dijon to Lyons; on the east of this ridge a wide and fertile plain is bounded by the mountains of Franche-Compté and Savoy; and on the west the country is hilly and less cultivated; the soil is various, but generally rich; the Seine, the Yonne, the Ain, the Saone, the Rhone, and other large streams, all of which are navigable, are the principal rivers; and the province being traversed by canals, enjoys the advantage of extended inland navigation.

Grain, fruits, tobacco, hemp, and flax, are enumerated among the abundant vegetable productions; the sheep reared in the more elevated parts of the province afford excellent wool, great part of which is manufactured in the country; and the average produce of its wines, some of which are highly esteemed, is stated at 100,000 hhds.

The population exceeds one million, and the inhabitants are employed in the manufacture of woollen stuffs, paper, and delft-ware, in the working of coal mines, and in smelting and manufacturing ores of iron. The chief towns of Burgundy are, Dijon, Auxerre, and Autun.

BURIAL, the interment of a person deceased, has been regarded in all countries as a sacred rite due from the living to the dead, and those who neglected to discharge this debt were supposed to be subject to the wrath of heaven. Among the Greeks and Romans, the performance of the rites of burial to their deceased friends and relatives, was reckoned

Burke. among the most inviolable obligations. Exclusive of that tender feeling which death cannot destroy, and that affectionate regard which reaches beyond the grave, the doctrine entertained by the Greeks and Romans, that the soul could not be admitted into the Elysian fields till the body had received the rites of burial, rendered them extremely attentive to the funeral obsequies of the dead. Those who were denied the rites of burial, were not permitted to enter the mansions of bliss till after the lapse of 100 years; and hence they considered it a duty upon all travellers who should meet with a dead body in the way, to cast three handfuls of dust upon it, one of which was destined to cover the head. The ancients also considered themselves peculiarly unfortunate if their mortal remains were not deposited in the tombs of their ancestors; and, on this account, it was usual to bring the ashes of those who died in foreign countries home, to be interred in the sepulchres of their fathers,—a practice which the pious care of the moderns is still disposed to observe, when it is not opposed by insurmountable difficulties. Among the ancients, some persons were refused the rights of burial, as public or private enemies,—such as betrayed or conspired against their country,—such as were guilty of sacrilege,—tyrants who were regarded as enemies of their country,—such as died in debt, whose bodies were considered the property of their creditors,—and certain offenders who suffered capital punishment. Even of those to whom funeral obsequies were granted, certain marks of disgrace attended their interment,—such as were killed by lightning, were buried in a place by themselves, because they were thought obnoxious to the gods,—those who squandered their patrimony, forfeited the right of being buried in the tombs of their ancestors,—and those who committed self-murder, were privately deposited in the ground without the usual solemnities.

Among the Jews, the rites of burial were denied only to such as were guilty of suicide; and the primitive church observed the same practice with regard to the same description of persons, while at the same time the more solemn funeral obsequies were refused to such as were unbaptized or excommunicated.

The place of burial has been different among different nations. The Jews buried their dead in the town, and the country, on the high-ways, in gardens, and upon mountains. Among the Greeks, the temples were the repositories of the dead in the primitive ages; but, in a later period of the history of that people, as well as of the Romans, and of other heathen nations, it was usual to bury their dead without their cities, and chiefly by the high-ways; and hence the propriety of the ancient monumental inscriptions, beginning with the address *Siste viator*, stop traveller. Among the primitive Christians, burying in cities was not practised for several centuries, nor was it usual to deposit the dead in churches till a much later period. The time of burying the dead, and the ceremonies which are observed during that solemnity, have been very different among different ancient and modern nations.

BURKE, Edmund, a celebrated orator and statesman, was a native of Ireland, and was born in Dublin in 1730, received the early part of his education at a private seminary, under the direction of Abraham Shackleton, a quaker, and became afterwards a student in Trinity college, Dublin. But at this period of his life no indications of great genius had appeared, excepting the publication of some essays of a political nature. He had attached himself particularly to the study of logic and metaphysics, and with these qualifications he offered himself a candidate for the professorship of logic in the university of Glasgow; but another, who it is not understood had so much to recommend him, was preferred. Burke.

After this disappointment he repaired to the metropolis, the great theatre in which the powers of genius are displayed to advantage, and he entered as a student of the Inner Temple; but although he was familiar with the great principles of jurisprudence, it is justly doubted whether his application to municipal researches was ever sufficient to qualify him for the details of legal practice; but the scantiness of his finances, it is well known, required exertion for an immediate supply, and obliged him to labour hard in contributing to the periodical publications of the day. These exercises afforded him an opportunity of acquiring a great command of style and language, and much facility of composition. But his mental exertions injured his health, and having called in the professional assistance of Dr Nugent, a countryman of his own, that gentleman invited and received him to his own house, till his health was restored; and during his residence at this time an attachment to the daughter of his host, who afterwards became his wife, commenced.

The publication of Mr Burke's *Essay on the Sublime and Beautiful* gave great celebrity to his character as a man of letters, and, beside the profits which this work brought him, it is said that he received about L.100 from his father; but great, indeed, must have been his embarrassment, and it is painful to record such an event befalling any literary man, when he was obliged to sell his books. But the work now alluded to introduced him to Sir Joshua Reynolds, Dr Johnson, Dr Goldsmith, and the principal men of letters and celebrity of the day. The *Annual Register*, begun in 1750, was for some time under the superintendence of Mr Burke, and it is said that his contributions to the political and historical departments of that work were the chief source of his emolument while he was engaged in it.

The political life of Mr Burke now commences. Accompanying Mr Hamilton, famous for his single splendid oration in the house of Commons, and hence known by the name of *Single-speech Hamilton*, to Ireland, but without any ostensible situation, he was rewarded with a pension of L.300 a-year, either through the influence of private friendship, or for some secret services. On his return to England he resumed his literary labours; and some essays, which appeared in a periodical publication, attracted the notice of the Marquis of Rockingham, and finally introduced him to that nobleman. He came into parliament in 1765, and it is said that he had acquired the facility of expressing his thoughts in public by frequenting clubs in the metropolis, in one of which, it is added, the powers of Mr Burke found a formidable antagonist in an elo-

Burke.

quent baker, who long annoyed the young orator by his popular declamation. Holding an official situation under the Rockingham administration, he supported the measures of the party; and when a change of ministry followed, he continued strong in opposition to the American war, during the whole period of that disastrous and expensive contest. At the close of lord North's administration in 1782, Mr Burke obtained, among his successors, the lucrative appointment of paymaster of the forces; and while he held an official situation, he introduced and carried his famous bill, which he had at a former period attempted unsuccessfully, for regulating and reducing the expenditure of various public departments. In the succeeding change of ministry, Mr Burke took his place among the ranks of opposition, and assumed a conspicuous station in the discussion of India affairs, and particularly in the famous impeachment of Mr Hastings, of which he was one of the principal leaders, and displayed a power and brilliancy of oratory which has been rarely equalled, and never surpassed either in ancient or modern times. The illness of the king, and the discussion of the regency bill, afforded him another opportunity for the display of his eloquence.

The progress of the French revolution produced a remarkable change in Mr Burke's politics. About the year 1790, he avowed in public that he had abandoned his old friends, and even some of the old principles which he had long maintained. The danger which seemed to threaten all ancient establishments was held out as an apology for this unexpected dereliction. But whatever may have been the cause of his vacillation, the associates with whom he now acted were not slow in rewarding his exertions in support of their measures, by liberal pensions, to the amount of nearly L.4000 a-year, and it was said that a peerage awaited him had he lived; but the death of an only son, who had just commenced his political career, is supposed to have hastened his own. He died at his seat at Beaconsfield, in 1797, when he had reached the 68th year of his age.

The following delineation, which appeared in a celebrated journal, with the exception of a little high colouring, is a pretty correct representation of his character. "Burke was a man of fine fancy and subtle reflection, but not of sound or practical judgment, or of high or rigid principles. As to his understanding, he was certainly not a great philosopher, for his works of mere abstract reasoning are shallow and inefficient; nor a man of sense and business, for, both in counsel and in conduct, he alarmed his friends as much, at least, as his opponents; but he was a keen and accomplished pamphleteer, an ingenious political essayist. He applied the habit of reflection which he had borrowed from his metaphysical studies, but which was not competent to the discovery of any elementary truth in that department, with great facility and success, to the mixed mass of human affairs. He knew more of the political machine than a recluse philosopher; and he speculated more profoundly on its principles and general results than a mere politician. He saw a number of fine distinctions and changeable aspects of things, the good mixed with the ill, and the ill mixed with the good; and, with a sceptical indifference, in which the exercise of his own ingenuity was always the governing principle, suggested various topics to qualify or assist the judgment of others. But, for this very reason, he was little calculated to become a leader or a partizan in any important practical measure; for the habit of his mind would lead him to find out a reason for, or against any thing; and it is not on speculative refinements, (which belong to *every* side of a question,) but on a just estimate of the aggregate mass, and extended combinations of objections and advantages, that he ought to decide or act. Burke had the power of throwing true or false weights into the scales of political casuistry, but no firmness of mind,—or shall we say, honesty enough,—to hold the balance. When he took a side, his vanity or his spleen more frequently gave the casting vote than his judgment; and the fieriness of his zeal was in exact proportion to the levity of his understanding, and the want of conscious sincerity. He was fitted by nature and habit for the studies and labours of the closet, and was generally mischievous when he came out, because the very subtlety of his reasoning, which, left to itself, would have counteracted its own activity, or found its level in the common sense of mankind, became a dangerous engine in the hands of power, which is always eager to make use of the most plausible pretexts to cover the most fatal designs. That which, if applied as a general observation on human affairs, is a valuable truth suggested to the mind, may, when forced into the interested defence of a particular measure or system, become the basest and grossest sophistry. Facts or consequences never stood in the way of this speculative politician. He fitted them to his pre-conceived theories, instead of conforming his theories to them. They were the playthings of his style, the sport of his fancy. They were the straws of which his imagination made a blaze, and were consumed, like straws, in the blaze they had served to kindle. The fine things he said about liberty and humanity, in his speech on the Begum's affairs, told equally well, whether Warren Hastings was a tyrant or not; nor did he care one jot who caused the famine he described, so that he described it in a way to attract admiration. On the same principle, he represents the French priests and nobles, under the old regime, an excellent moral people, very charitable, and very religious, in the teeth of notorious facts—to answer to the handsome things he has got to say in favour of priesthood and nobility in general; and, with similar views, he falsifies the records of our English revolution, and puts an interpretation on the word *abdication*, of which a school-boy would be ashamed. He constructed his whole theory of government, in short, not on rational, but on picturesque and fanciful principles; as if the king's crown were a painted gew-gaw, to be looked at on gala-days; titles an empty sound, to please the ear; and the whole order of society a theatrical procession. His lamentations over the age of chivalry, and his projected crusade to restore it, is about as wise as if any one from reading the Beggar's Opera, should take to picking of pockets, or from admiring the landscapes of Salvator Rosa, should wish to convert the abodes of civilized life into the haunts of wild beasts and banditti. On this principle of false refinement, there is no abuse, nor system of abuse, that does not admit of an easy and triumphant defence; for there is something which a merely speculative inquirer may always find out, good as well as bad in every possible system, the best or the worst; and if we can once get rid of restraints of common sense and honesty, we may easily prove by plausible words, that liberty and slavery, peace and war, plenty and famine, are matters of perfect indifference. *Edin. Rev.*

BURLINGTON, a county of the state of New Jersey in North America, extends between the Delaware and the Atlantic ocean, about 60 miles in length and 30 in breadth, includes about 250,000 acres, of which nearly two-thirds are in a state of improvement, is generally level and well watered, is divided into eleven townships, and contains more than 16,000 inhabitants.

BURLINGTON, the capital of the county of the same name in New Jersey in America, stands on the east bank of the Delaware, and is about three miles long; is chiefly built on an island, from which communications are formed by causeways or bridges with the main-land. The streets are regular and spacious; several churches, an academy, the court-house, and market-houses, are the principal public buildings; the harbour is commodious, and the number of inhabitants exceeds 1000; but, from its vicinity to Philadelphia, the trade is not considerable.

BURNET, Thomas, a learned writer on theology, but better known as the author of a Theory of the Earth, was a native of Yorkshire, studied at Cambridge, and was for some time under the tuition of the celebrated archbishop Tillotson. He was elected master of the Charter-house in London, took orders in the church, and about the year 1680 published his *Sacred Theory of the Earth,* which appeared first in Latin, and is remarkable for the elegance and purity of the style, and was afterwards translated into English; but has been admired more for ingenuity than sound science or correspondence with the details of scripture history. He was the author of several other works, and particularly on the *Faith and Practice of Christians,* and on the *State of the Dead,* &c. also in Latin, and translated; but excepting his Theory of the Earth, none of his writings is much read. He was chaplain and clerk of the closet to king William, but never enjoyed higher promotion, arising, it is supposed, from the unsoundness of his theological opinions. He died in 1715.

BURNET, Gilbert, a learned divine of the church of England, was born at Edinburgh in 1643, was educated at Aberdeen, became a preacher at the early age of 18, and, after prosecuting his theological studies in England and on the continent, he returned to Scotland, was admitted to priests orders, and was appointed to the living of Saltoun in East Lothian; and in a few years afterwards he was nominated professor of divinity at Glasgow, where he was greatly distinguished by his moderation. The rising influence of Dr Burnet made him known to the duke of Lauderdale, who was then at the head of affairs in Scotland, and through him he was introduced to Charles II., who frequently consulted with him in matters of state. Having obtained the favour of the duke of York, he was requested to remain in England; he then resigned his professorship at Glasgow, and was soon after appointed lecturer of St. Clements, and preacher at the Rolls chapel; and about 1697, he published his *History of the Reformation,* for which he received the thanks of both houses of Parliament.

Dr. Burnet had been twice offered a bishopric in Scotland, and again in England he declined the same dignity, because it was trammelled with certain conditions which were incompatible with his sentiments of religious toleration. His well known attachment to the protestant interest rendered his presence in England neither safe nor agreeable, after the accession of James; and having obtained permission he left the kingdom, lived for some time in great retirement at Paris, and having completed an extensive tour on the continent, reached Holland, and was invited by the prince of Orange to the Hague. Admitted to the confidence of the Stadtholder, he became an object of great jealousy to James; and the circulation of single sheets of an *Account of his Travels,* in different parts of England, the object of which was to expose popery and arbitrary power, occasioned a prosecution for high treason to be raised against him, both in England and Scotland; but he avoided the consequences by obtaining a bill of naturalization, in the view of marrying a Dutch lady, his second wife. He was now a subject of the United Provinces, and, it is understood, contributed not a little to promote the design of the prince of Orange in aspiring to the crown of Britain. He accompanied the prince to England in the capacity of chaplain; and, when William was seated on the throne, his services were rewarded with the see of Salisbury. In the succeeding year, he published a pastoral letter on the oaths of allegiance and supremacy. The opinion which he expresses of the right of conquest, by which king William and queen Mary held the sovereignty, gave such offence to both houses of Parliament, that it was ordered to be burned by the hands of the common executioner. *The Exposition of the 39 Articles* appeared in 1699, and excited some investigation in the church courts. He had formed a scheme for augmenting the poor livings, which was finally accomplished by the act of queen Anne; and *The History of his own Times,* left for publication at his death, appeared under the direction of his son in 1723 and 1734, in two volumes folio, and is a curious record of the eventful period to which it alludes. Bishop Burnet died in 1715, and was buried in St. James's, Clerkenwell, where a monument is erected to his memory. This eminent prelate was not more distinguished by his learning and industry, than by his moderation, and the exemplary and faithful discharge of his ministerial functions.

BURNET, James, Lord Monboddo, a celebrated writer on ancient metaphysics, and descended from an ancient family in the north of Scotland, was born in 1714; and being destined for the profession of the law, he was educated at the universities of Aberdeen, Edinburgh, and Leyden, was admitted an advocate at the Scottish bar in 1737, and was promoted to the bench in 1767, when he assumed the title of Lord Monboddo, from the name of his patrimonial estate.

The professional life of Lord Monboddo, either as a lawyer or a judge, was not diversified by many incidents. He was engaged as one of the council in the famous Douglas cause, which at that time excited so much interest; and, by his perseverance, it is said, the present family succeeded in establishing a legal claim to the immense property which was the subject of dispute. But as a man of letters, and particularly as an admirer of the manners and philosophy of the ancients, he is well known to the world. His first publication on the Origin and Progress of Language appeared in 1773, and this work was completed in six volumes, published at different periods. The first volume of his treatise on Ancient Metaphysics appeared in 1778, and the sixth and last on the same subject was presented to the world only a short time before his death. In these works, the strong prepossession of the author in favour of ancient manners and learning, and particularly his admiration of Grecian literature and philosophy, which was excessive, led him into many peculiarities, and have exposed him to the shafts of ridicule, while, in excluding or disregarding the improvements of modern times, he has betrayed the narrowness of his own views. But even with this want of discrimination, his profound skill in ancient languages, and extensive knowledge of ancient philosophy, although little accommodated to the present state of literature, and of no great practical utility, must be readily acknowledged.

The manners of Lord Monboddo partook a little of the same peculiarities which distinguished his sentiments and modes of thinking. Regarding the improvements of modern times as a mark of degeneracy from the hardy character and vigorous habits of the ancients, he declined to indulge himself in many of the accommodations of the age in which he lived. In his annual visits to London he performed the journey on horseback, and continued the practice till he was upwards of 80 years of age. Even in his amusements he imitated the ancients; he was fond of athletic exercises, was accustomed to indulge both in the cold and warm bath, and even practised a mode of anointing the body with a kind of saponaceous mixture. But to his praise it is recorded, that he was temperate in his habits, affectionate in his domestic concerns, a kind and indulgent landlord, an upright judge, and kind and benevolent in his disposition to all. He died at Edinburgh in 1779, when he had reached the 85th year of his age.

BURNING, the process of combustion, or that change which bodies undergo with the extrication of light and heat. See Chemistry.

BURNING THE DEAD, a practice which has prevailed among many nations, both in ancient and modern times. This practice was known among the Jews, was common among the Greeks and Romans, by whom it was observed with much solemnity; and similar ceremonies are described among the customs of the ancient Gauls and Germans; and are familiar among some rude people, as well as among some of the civilized nations of the east in modern times.

BURNING INSTRUMENTS, are instruments constructed on optical principles, by which an intense degree of heat is produced. These instruments are either mirrors or lenses, which concentrate the rays of the sun, either by reflection or refraction. When the effect is produced by reflection, the instrument is denominated catoptric, and by means of refraction it is called dioptric. Powerful instruments of this kind have been known both in ancient and modern times. It is recorded by different ancient authors, that Archimedes set fire to the Roman fleet at the siege of Syracuse, by means of a burning mirror, which, it is said, was composed of small square pieces of glass, moving every way upon hinges, and when placed in the sun's rays directed them upon the Roman fleet, so as to reduce it to ashes at the distance of a bow shot. By means of a similar instrument, constructed by Proclus, the Gothic ships which blockaded Constantinople in the time of Anastasius were destroyed; and a burning mirror on the same principle is supposed to have been constructed by Anthemius, about the end of the 5th century, and in the time of Justinian. But the most celebrated burning mirrors of modern times, were those of Vilette, a French artist; of Tschirnhausen, made of polished copperplate; of the celebrated naturalist Buffon; and of one on an improved construction by Peyrard. Of dioptric burning instruments, the most famous are those of Tschirnhausen, Trudaine, Buffon, and one constructed by Mr Parker of London, at an expence of L.700. This instrument was three feet in diameter, three and a quarter inches thick at the centre, the focal distance six feet, eight inches the diameter of the burning focus, and the weight of the whole lens exceeded two hundred pounds. A subscription was attempted for the purpose of defraying the expence of this fine instrument, but it failed; and the instrument itself was purchased by Captain Macintosh, who accompanied Lord Macartney in his embassy to China; and is now probably deposited among many ingenious and valuable presents, the use of which is unknown to the Chinese.

BURNS, Robert, the far-famed Scottish poet, was a native of Ayrshire, and was born on January 25th, 1759, in a cottage near the church of Alloway, and those scenes which are so finely commemorated by his muse. His father, from the north of Scotland, had been nursed in the school of misfortune; had acquired much knowledge of men and manners; but, possessed of stubborn, ungainly integrity, and headlong ungovernable irascibility, disqualifying circumstances to insure success in the world, as the poet himself strongly expresses it, he was doomed through life to be a poor man. When he settled in Ayrshire, he was engaged as gardener and overseer to a gentleman near the spot where Robert was born; his affairs were unprosperous; he changed his residence twice to different farms; but adversity and poverty still pursued him, till death at last relieved him from his sorrows, and his all was seized by his creditors.

The education of the poet was extremely scanty. He received his elementary instruction in English at a private country school taught by Mr Murdoch, who has drawn up an excellent account of the early part of his life; and to the same teacher he was indebted for a smattering of French. He derived his knowledge of arithmetic from his father; and acquired the practice of writing at the parish school of Dalrymple. The books recommended by his father, or which he perused at a future period of his life before he was known as a poet, were Salmon's and Guthrie's Geographical Grammars, the Spectator, Pope's Works, some Plays of Shakespeare, Locke's Essay on the Human Understanding, Stackhouse's History of the Bible, Hervey's Meditations, Allan Ramsay's Works, and a Collection of English Songs. He had dwelt with enthusiasm on the life of Hannibal, and the History of Sir William Wallace, the Scottish patriot; and he had drawn a great deal of legendary lore in his early years from an old woman, a resident in the family, and remarkable for her ignorance, credulity, and superstition. Such was the extent of education and reading which fell to the lot of Burns.

His first attempt at rhyme, as the poet himself relates his story, was in his 16th year, in the composition of some verses in praise of Mary Campbell, a Highland girl, who had been his fellow-reaper in the field during harvest, and who was the object of his first attachment. When the autumnal labours were over, they parted never to meet again; but the intelligence of her death restored to his heart the softened image of his early passion, and awakened his muse to one of her tenderest effusions, in the *Address to Mary in Heaven.* About the 23d year of his age he spent some time in Irvine, to qualify himself for the business of flax-dressing; but an accidental fire destroyed his little property, made him abandon this undertaking, and brought him back to his family and the labours of the field. After the death of his father, which happened soon after, the family, with a laudable attachment to their mutual interests, united their means and exertions in the cultivation of a farm in a different part of the county. But an ungenial soil, and a succession of bad crops, rendered their labours unproductive, and again involved them in pecuniary embarrassments. At this time Burns became known in the neighbourhood as a poet; some of his satirical and humorous productions, circulated in manuscript, were much read, and greatly admired; his convivial habits had acquired some influence over his conduct; his attachment to his future wife had commenced, and he had become a father before he was a husband. Soured by disappointment, and pressed by penury, the poet had resolved to seek better fortune in a distant land; but the scantiness of his resources left him no alternative in procuring a passage to Jamaica, to which his views were directed, but to come under indentures to serve for a fixed period as a planter. The publication of the first edition of his poems by subscription at Kilmarnock, relieved him in some measure from his difficulties; yet still he contemplated his voyage across the Atlantic; he had bidden adieu to his native land; and his clothes were packed up, and on the road to Greenock, from which he was to embark, when his poems had attracted the notice of Dr Blacklock; and a letter from that amiable poet and excellent man induced Burns to visit the metropolis of Scotland.

A new scene opened before the bard when he arrived in Edinburgh, in the winter of 1786 and 1787. Some account of the Ayrshire Ploughman, and some extracts from his poems, had appeared in the Lounger, then publishing periodically; his society was courted by all ranks; and a new edition of his poems brought him about L.700 Sterling. With this favourable turn in his affairs, it must ever be regretted that the poet had not the prudence or resolution to return immediately to his former habits of industry; and yet it is scarcely to be wondered at, that a mind less ardent than that of Burns was unable to oppose the current of dissipation along which he was carried. He spent part of the succeeding summer and autumn in tours through different parts of the country, but seemingly without any determinate object in view; and he returned to Edinburgh in the following winter, in the hope, it is supposed, of procuring some permanent appointment; but the great friends which his genius had secured him, and the powerful patrons who pretended to take an interest in his welfare and reputation, either thought him unworthy, or were unwilling to procure for him a better place than the humble office of an excise-officer, than which no situation could be worse calculated to the habits and character of Burns. At the same time he rented a farm in Dumfries-shire on favourable terms, and soon after fixed his residence with his family upon it; but it soon appeared that his attention was too much distracted in the pursuit of two very different objects, to encourage the hope of flattering success in rural affairs; and in his excise concerns he was led into that kind of society from which it would have required more fortitude than the poet now possessed to depart without excessive indulgence. His farm was neglected, disappointment and derangement of his affairs followed, and, having resigned his lease, he retired to the town of Dumfries, with no other income than the salary of an excise officer for the support of his young family.

The residence of the poet in Dumfries was by no means favourable to his habits. His society was courted by the idle, the gay, and the dissipated, who were delighted with his conversation, or amused with the sportive sallies of his humour, or the happy effusions of his wit; and perhaps many who had neither capacity nor taste to admire the powers of his genius, were eager to solicit his acquaintance and society, that they might be able to boast of an intimacy with so extraordinary a man. The closing scene of the life of Burns now approaches. While he was embarrassed in his worldly affairs, and his mind was clouded with gloomy reflections, partly arising from his own imprudence, and partly induced by the destitute and helpless situation in which he foresaw his family would be placed, his body was fast wasting with disease. In the end of June 1796, he retired to the shores of the Solway Frith, for the purpose of trying the effects of sea-bathing. On the 18th of July he returned to Dumfries, in a state of great weakness; a fever was upon him, which continued to increase, and on the fourth day relieved him from the disappointments, the cares, and the sufferings of this world, at the early age of thirty-seven.

Every mark of respect was paid to the memory of the bard at his funeral. Being a member of a volunteer corps, he was buried with military honours, and the solemn procession was attended, not only by the volunteers, but by the regular infantry and cavalry then stationed in Dumfries, as well as by the principal inhabitants of the town and neighbourhood. But it was not the least affecting incident to the family of the departed poet, that, at the very time that his mortal remains were committed to the earth, his afflicted widow brought forth a son. This infant soon followed his father to the same grave. Four sons survived him, and for them and his widow, who were left in great indigence, a subscription was entered into, and a liberal sum raised.

It is melancholy to reflect on the last scene of the poet's sufferings; and nothing can be a stronger proof of the anguish of his mind, than the dread under which he laboured of being thrown into prison for a debt of no great amount; even in the rage of the delirium which prevailed during the last days of his existence, the horrors of a jail haunted his imagination; yet what hand was stretched out to relieve his distress? Who, of all his numerous friends and patrons, contributed to raise the depressed spirits of the afflicted bard? What, indeed, must have been his difficulties, when the lofty mind of Burns, who, whatever were his faults and failings, never betrayed a mean or mercenary spirit, was compelled to solicit L.5, that he might be enabled to ward off the danger which alarmed his fears. But the world, seemingly conscious of the neglect which he experienced while living, is determined to make ample amends by every expression of regard to his posthumous fame. A magnificent mausoleum has been erected over his ashes at Dumfries, the expence of which was defrayed by subscriptions, not only in Britain, but in distant quarters of the globe. Similar monuments are proposed to be raised to his memory, and the anniversary of his birth is celebrated in all parts of the kingdom.

Numerous editions of the works of Burns have appeared since his death, one of which, in four volumes octavo, has an elaborate life of the poet prefixed, by the late Dr Currie of Liverpool, and was published under his superintendence for the benefit of his widow and family. The profits of this edition, it is understood, afforded a very handsome sum. Beside the poems which appear under his own name, Burns contributed many songs to the Museum, published by Mr Johnson, engraver in Edinburgh, as well as to the more elegant and perfect work of Mr Thomson of the same place.

BURNTISLAND, a royal borough of Fifeshire in Scotland. See Bruntisland.

BURSA, or Burse, originally denoting a purse, is used, among middle age writers, to signify a little college or hall in a university, for the residence of students; and in more modern times is applied to a foundation for the support of poor scholars in their studies, who are hence called Bursars.

BURTON, Robert, a learned English author, was a native of Liecestershire, and was born in 1576, was educated at Oxford, and having entered the church, was fortunate in being presented with several livings. But his name has been transmitted to posterity as the author of a singular production, entitled the *Anatomy of Melancholy*, a work which had a great circulation; and from which it appears, from the enquiries of Dr Ferriar, published in the Manchester memoirs, that the celebrated Sterne borrowed some of the most striking passages of his works. Mr Burton, it is said, was strongly attached to astrology; and having predicted the period of his own death, committed suicide rather than allow his calculation to fail.

BURTON UPON TRENT, a borough town of Staffordshire, stands on the west bank of the river Trent, is a place of considerable antiquity, contains about 4000 inhabitants, who are occupied in the manufacture of cotton and woollen stuffs, iron mongery, and hats. Burton is well known for its excellent ale, which finds a market not only throughout the kingdom, but is exported to different parts of the continent. The Trent, which is navigable for boats, and the canals which communicate with the principal parts of England, afford great facilities to the trade of this place.

BURY, a borough town of Lancashire, in England, stands on the east bank of the Irwell, and has risen of late years to considerable importance, by the introduction of different manufactures. The population exceeds 7000; coarse woollen goods, and all kinds of cotton stuffs, are manufactured; bleaching and calicoe printing establishments, on the banks of the river, are extensive and prosperous. Bury is 9 miles from Manchester, and 194 miles from London.

BURY, ST EDMUNDS, a borough town of the county of Suffolk in England, is situated on the river Sark, and is highly celebrated for its pure air and genial climate; is a place of considerable antiquity; and the remains of a monastery, which is said to have been one of the richest in the kingdom, still exhibit an elegant specimen of its former splendour. The churches and some of the other public buildings are fine edifices; the population is about 7000, and the only manufactures are woollen stuffs of a fine fabric.

BUSCHING, the celebrated author of a System of Geography, was a native of Germany, was born in 1724, and received the early part of his education and his instruction in the learned languages from the minister of a German congregation at Copenhagen, and afterwards studied divinity at Halle. Being appointed to superintend the education of a young nobleman, he accompanied his pupil to St Petersburgh in 1749; and at this time, it is said, he projected the new system of Geography which he afterwards executed. He was afterwards nominated a professor of philosophy at Gottingen; and in 1761 he was invited to St Petersburgh, to accept of the office of pastor to a Lutheran congregation; and during his residence in that metropolis he founded a public school, which obtained considerable celebrity; but some differences having arisen he returned to Germany, remained some time at Altona, and in 1766 he was appointed director of a Gymnasium at Berlin, where he died in 1793.

Busching was distinguished as an author by his learning and indefatigable industry; his geographical work alone, which was published at different periods from the year 1754, and was completed in six 4to volumes, affords ample evidence of his ability and perseverance.

BUSHEL, a dry measure of capacity, and particularly employed for grain, contains four pecks or eight gallons, or one-eighth of a quarter. By the enactment of Henry VII. a bushel must contain eight gallons of wheat; the gallon eight pounds of wheat, troy weight; the pound twelve ounces, troy weight; the ounce twenty shillings, and the shilling thirty-two grains, or corns of wheat, growing in the midst of the ear. When this standard bushel was measured before the house of Commons in 1696, it was found to contain 2145.6 solid inches of water, and the weight of the water amounted to 1131 ounces and 14 pennyweights troy. The bushel varies greatly in different parts of England. At Abingdon and Andover it contains 9 gallons; at Appleby and Penrith, for pease, rye, and wheat, 16 gallons, and for oats, barley, and malt 20 gallons; at Carlisle, 24 gallons; at Chester for wheat and rye 32 gallons, and for oats 40 gallons; at Dorchester for malt and oats 10 gallons; at Falmouth for coals 16 gallons, and for other commodities 20 and 21 gallons; at Kingston upon Thames $8\frac{1}{2}$ gallons; at Newbury 9 gallons; at Wycombe and Reading $8\frac{1}{4}$ gallons; and at Stamford 16 gallons.

BUSHIRE, a sea-port town of Persia, at the extremity of a peninsula in the Persian gulph. The town is of a triangular form, washed on two sides by the sea, and fortified on the land side by a wall and bastions; the streets are narrow, and the houses, which are chiefly of mud, are mean and low, but the harbour is commodious, and a considerable trade is carried on with India, and with the interior of Persia, by means of caravans. The population is stated at 10,000.

BUTCHER is a person who slaughters cattle for the use of the table, or who cuts up the flesh and retails it. Three descriptions of persons were employed in this business among the ancient Romans; one provided hogs for the market, another furnished cattle and other animals, and under them was a subordinate class, whose office was to kill the animals. Two classes of butchers are recognised in London; *carcase butchers*, who slaughter animals in great numbers, and dispose of meat to the *retail butchers*, who are dispersed in different places for the supply of their customers. The company of butchers in London was incorporated in the third year of the reign of James I. Numerous legislative enactments have been made for regulating the trade of butchers, with the view of bringing sound meat into the market, of preventing nuisances in killing cattle, and the injuring of hides by cutting, or allowing them to become putrid, to the prejudice of the tanner.

BUTE, an island in the frith of Clyde, on the west coast of Scotland, is about 15 miles long, and three miles broad, including about 24,000 Scotch acres. The coast is rocky, and indented with several bays, and the highest land is not more than 400 feet above the level of the sea. The northern district of the island is chiefly composed of primitive rocks, as micaceous and argillaceous schistus; and of the latter, the common roof slate, quarries have been opened, and extensively wrought. Red sand stone is also a prevailing rock in many parts of the island, and rocks of trap or basalt are also common. Speculative geologists have encouraged the hope of discovering coal, and attempts have been made to search for that valuable mineral, but they were unsuccessful; and it may be added, that any future trial for the discovery of coal in such rocks, with which it is never associated, will have a similar termination.

The soil of Bute is generally of a light and sandy nature, but answers well for every kind of husbandry. The island itself furnishes abundance of manure from sea-weed, extensive beds of sea shells, and limestone, in different places. Much of the land is well enclosed and subdivided, and the chief productions are barley, oats, and potatoes, for which Greenock and Glasgow offer a ready market, as well as for their cattle. The surrounding sea abounds with excellent fish, and numerous wild fowl frequent the coast and the inland parts of the country.

The marquis of Bute is the principal proprietor of the island, and he has an elegant mansion embosomed in thriving plantations on the eastern shore. The population, which in 1801 amounted to 6,106, has since that time increased. The inhabitants are chiefly employed in agriculture, fishing, and cotton spinning. Rothsay is the capital of the island and of the county which includes Arran, the two Cumbraes, and Inchmarnoch. The population of the county, estimated in 1801 at 11,791, had increased in 1811 to 12000.

BUTLER, Samuel, author of Hudibras, a well-known burlesque and satiric poem, was born at Strensham in Worcestershire in 1612. The particulars of his early life are little known, and have been variously represented. He is imagined to have studied for some time at Cambridge or Oxford; but such a supposition, in the absence of satisfactory evidence, is quite unnecessary to account for the range of learning displayed in his singular production. As clerk to Mr Jeffreys, an eminent justice of the peace in his native county, he had opportunities, not only of study, but for recreation, especially in music and painting; and being subsequently an inmate in the family of the countess of Kent, he enjoyed the advantages of a good library, and an acquaintance with the illustrious Selden, one of the most erudite men of his time. Why he relinquished this situation cannot be ascertained. He afterwards resided with Sir Samuel Luke, one of the chiefs of the Puritan party, whose principles and practices he has represented in so ludicrous and sarcastic a manner. On the restoration of the royal family, he was made secretary to the earl of Carbury, then president of Wales, who gave him the stewardship of Ludlow castle. But these rewards were not equal to his expectations, nor perhaps suitable to his abilities. The publication of part of his poem procured him praise enough at court, and Lord Clarendon excited his hopes of obtaining something worthy of royal gratitude. But the promises of that nobleman were never fulfilled; and the neglect of a man who had contributed so much, as Butler appears to have done, to the merriment and triumph of the prospering cause, is one of the many instances of selfishness and ungenerous caprice in the conduct of the Second Charles. How much some of his contemporaries blamed such ingratitude, is manifest from an anecdote related by Packe, in his Life of Wycherly, which, besides, presents a striking likeness of the times, and of one of its principal characters. "Mr Wycherly had always laid hold of any opportunity which offered of representing to the duke of Buckingham (Villiers) how well Mr Butler had deserved of the royal family, by writing his inimitable Hudibras; and that it was a reproach to the court, that a person of his loyalty and wit should suffer in his obscurity and under the wants he did. The duke always seemed to hearken with attention enough; and after some time undertook to recommend his pretensions to his majesty. Mr Wycherly, in hopes to keep him steady to his word, obtained of his grace to name a day, when he might introduce that modest and unfortunate poet to his new patron. At last an appointment was made, and the place of meeting was agreed to be the Roebuck. Mr Butler and his friend attended accordingly; the duke joined them; but, as the d—l would have it, the door of the room where they sat was open, and his grace, who had seated himself near it, observing a pimp of his acquaintance (the creature, too, was a knight) trip by with a brace of ladies, immediately quitted his engagement, to follow another kind of business, at which he was more ready than in doing good offices to men of desert, though no one was better qualified than he, both in regard to his fortune and understanding, to protect them: and from that time to the day of his death, poor Butler never found the least effect of his promise." He died in 1680, and was buried in Covent-garden church-yard, at the cost of his benefactor Mr Longueville, who, in vain, solicited a subscription for his interment in Westminster-abbey. About sixty years after his death, the munificence of Mr Barber, a printer, mayor of London, raised a monument for him in this latter place, bearing an inscription, which pointedly alludes to the poverty of his life.

The first part of Hudibras was published in 1663; the second in the following year; and a third, which still leaves it imperfect, in 1678. He was author of several other works, some of which were published long after his death. But they are of inferior merit, and are comparatively little known. A work like Hudibras is enough for a single reputation. It is quite an original, full of peculiar and extraordinary qualities, in vain sought for in the numerous productions which have imitated its manner, and is perhaps more extensively read and relished than any piece of poetry of equal length in our language. This distinction it is impossible to explain, consistently with the objections which have been stated against its method, its style, its story, and its principles, without admitting it to possess some great and interesting excellencies. Its fame has not been confined to our own country, although it utterly baffles the endeavours of the translator, and its merits can only be properly appreciated by a native. "It is one of those compositions," says Dr Johnson, "of which a nation may justly boast;"—and the name of Butler "can only perish with his language."

BUTLER, Joseph, a learned English prelate, was born at Wantage in Berkshire in 1692. His father, a respectable shopkeeper, and a member of the presbyterian denomination, perceiving the studious disposition of this the youngest of eight children, sent him, after some preparatory education, to an academy, superintended by Mr Jones, in which he applied himself with uncommon ardour to several branches of literature. It was in this seminary, amid a multiplicity of pursuits, that he gave the first fruits of that profound and speculative intellect which was destined to obtain such commanding influence in a peculiar department of learning. In seriously perusing Dr Clarke's famous Demonstration of the Being and Attributes of God, which then attracted general notice, he thought he perceived some obscurity and imperfection in the mode of reasoning adopted by that celebrated author. His doubts were successively transmitted by letters to the doctor, who had the penetration to discover the sagacity of his unknown correspondent, and the politeness to reply to him. The friendship of that great man was a natural consequence of the acquaintance which afterwards took place between them, and contributed to a material change in the views and sentiments of young Butler, who henceforth, in opposition to the remonstrances of his father and the wishes of his most intimate associates, resolved to attach himself to the church of England. In prosecution of his new plan he removed to Oriel college, Oxford, where he was admitted a commoner in 1714, and where he was afterwards ordained for the ministry in the establishment.

Through the recommendation of Dr Clarke and other friends, he was appointed, at the age of 26, to the honourable office of preacher at the Rolls chapel. Here he delivered fifteen sermons, which were afterwards published, and which confirmed his reputation as one of the most original and powerful reasoners on the important subjects of natural religion and moral science. These singular productions will ever be esteemed by philosophical inquirers, but are utterly destitute of those graces and embellishments which allure the fancy and warm the feelings of superficial readers. His friends did not neglect his preferment, while he himself was wholly occupied in abstruse speculation. He was presented to the benefice of Haughton, and then to the rectory of Stanhope, in which he devoted seven years to the discharge of parochial duties. But this seclusion proving injurious to his too melancholic disposition, Mr Secker, who had all along urged his advancement, again succeeded in his favour, and obtained for him the appointment of chaplain to Lord Chancellor Talbot, which required that a considerable portion of his time should be passed in town. He was in two or three years time made clerk of the closet to queen Caroline, who appears to have been fully sensible of his great merits. It was shortly after being chosen to this creditable office that he published the work by which he is best known, and which, by its substantial excellencies and importance, must perpetuate his name while sound reasoning and good sense are esseemed among mankind. The treatise now alluded to, and which no scholar need be informed is, "The Analogy of

Religion, Natural and Revealed, to the Constitution and Course of Nature," and is one of those few but enviable productions, which it is impossible for any candid man, whatever may be his opinions, to have carefully read once without admiration, and which it is no less impossible to re-peruse, however frequently, without finding his admiration justified and heightened. Soon after the death of the queen, who recommended him to the notice of her consort, our author was promoted to the bishopric of Bristol, to which, at no great distance of time, was added the deanery of St Paul's, London. While in this latter office, he was sometimes called to preach on public occasions. The sermons then delivered were printed, and are generally found in the same volume with those which he formerly preached at the Rolls. In 1746 he was made clerk of the closet to the king, and in 1750, was translated to the see of Durham,—a preferment well suited to the generosity and beneficence of his character, but which his increasing infirmities did not suffer him long to enjoy. His primary, and indeed only charge to the clergy of that diocese, the object of which was to enforce attention to the forms and ceremonies of religion, exposed him to no small censure, as leaning to the superstitions of popery. But it appears no way difficult to reconcile the whole of his sentiments in that discourse with the principles and the practices of the communion to which he belonged; nor is there the slightest foundation for an assertion which was made 15 years after his decease, that he died in the faith of Rome. Archbishop Secker, bishop Halifax, and others, have amply vindicated his memory from this aspersion. He ended his days at Bath, where he had gone for the recovery of his health, on the 16th June 1752, aged 60, and was interred in the cathedral at Bristol. Dr Butler was never married. He is not known to have published any other works than what have been enumerated, and two Dissertations on Personal Identity and the Nature of Virtue; but a treatise on Faith has been ascribed to him, perhaps on doubtful evidence.

BUTOMUS, Flowering Rush, or Water Gladiole, a genus of plants belonging to the Enneandria class. Butomus Umbellatus is a native of England.

BUTTER, an unctuous substance, of a yellow colour, and an agreeable sweetish taste, which is prepared from milk, by the well known process of churning. In many of its properties it resembles oily bodies. The Greeks, it is supposed, derived their knowledge of the process of making butter from the Scythians; and, according to some historians, the Romans were indebted to the Germans for the preparation and use of this substance. The word is frequently used in the translation of the Scriptures of the Old Testament; but doubts are entertained whether the original word, which is thus translated, ought to be taken in that sense. See Agriculture.

BUTTON, an appendage of dress, which is sometimes employed as an ornament, and sometimes for useful purposes, in fastening and securing different garments. The fabrication of buttons is a very extensive manufacture in some parts of England; and the cheapness of the produce of this manufacture is a proof of the facility with which is is carried on.

BUTTON-MAKING.

Buttons are made of various materials, as horn, bone, wood, and leather, which are either covered with thread, hair, silk, or some other fibrous substance, or are used plain; more commonly they are made of different kinds of metal, which are either polished, plated, or gilt; and another kind of button is made with a mould of bone or wood, covered with cloth of the same kind as the garment to which it is attached.

Moulds.—Button moulds are usually made of bone, and this operation is performed with great dexterity by means of the lathe, and with appropriate instruments. The larger moulds are first cut out, and afterwards smaller ones are cut out from the remaining spaces, and the minute and the small fragments, saw dust, or shavings, are disposed of for case-hardening iron toys and different kinds of cutlery, and what is unfit for this purpose is sold to the farmer for manure; so that no part of the materials in this manufacture is lost. Button moulds are made with astonishing rapidity; young persons of ten or twelve years of age acquire such facility in the operation, as to be able to cut out 30 moulds in a minute. Moulds of a larger size are made of wood, of a hard and tough quality, as oak, elder, or beech.

Covering of buttons.—Button moulds, according to the fashion of the present day, are generally covered with a piece of the cloth of the garment to which they are attached; but in former times they were covered with pieces of cloth made of silk, mohair, gold twist, and other expensive materials. These substances, formed into thread, were wrought or twisted on the mould according to different patterns, and were sometimes still farther ornamented with silver or gold sewed on the surface.

Cleansing hair or silk buttons.—To remove the superfluous projecting hairs or filaments of the material with which the button is covered, a number of buttons is introduced into a kind of iron sieve, which is called by the workmen the *singeing box.* A little spirit of wine is then poured into a shallow iron vessel and set fire to, when the workmen move the singeing box with the buttons briskly over the flame of the spirit, so that all the loose projecting filaments are burnt off, and, when the operation is properly performed, without any injury to the buttons. They are then put into a leather bag, of a conical form, and about three feet in length; and crumbs of bread being introduced into the bag at the same time, it is briskly shaken with a particular kind of motion, by which the buttons are cleaned, and rendered beautiful and glossy, and fit for the market.

Button shanks.—The shank, or eye of the button, as it is sometimes called, is made of iron or brass-wire, and in its progress passes through several operations. The wire is first coiled round a flat steel bar, with the two opposite sides rounded. When the coil of wire is completed, it is slipped off the bar, and a wire fork being introduced, it is laid upon an anvil, and struck with a punch, the edge of which presses the wire between the branches of the fork, and the wire being cut with shears at the place marked by the punch, each coil is divided into two button shanks. The wire is usually rolled on the steel-bar by screwing one extremity into the spindle of a lathe, and the different operations are performed with great rapidity.

But an ingenious improvement in this simple operation, has been introduced at Birmingham. A machine is so contrived, that merely by turning a winch it supplies itself with the wire from a reel, and, after performing the different operations of cutting and bending to the proper form, delivers the shank completely finished. One shank is formed at each turn of the winch, and the power required to set the machine in motion is so small, that the strength of a boy is sufficient for the purpose. But the inventor has carried his improvement still farther; he employs a steam-engine as the moving power; in this way a number of machines is wrought in the same apartment, and, by this wonderful abridgment of labour, can produce these articles at a price which little exceeds the original cost of the wire.

Horn buttons.—Horn buttons are either made with shanks fixed to them, or they are fastened with thread by means of holes drilled for the purpose. When the button is secured in the latter way, it is generally made concave on the surface, that the threads by which they are secured to the garment may be preserved from wearing.

The hoofs of cattle furnish the material for the fabrication of horn buttons; and in the process by which they are made, advantage is taken of the property of horn becoming soft by means of heat. The hoofs are first boiled in water till they are soft; they are then cut into parallel slips of the breadth of the intended diameter of the button by means of a knife, which acts in the form of a lever on the bench or table where the operation is performed; and the slips are again cut into squares, the angles of which being cut off, each piece is brought nearly to the size of the button. The pieces are then put into a bath composed of logwood, galls, and copperas, for the purpose of communicating a black colour, after which they are dried for a week. The dies which give the impression to the button are fixed to the number of eight or twelve, according to circumstances, in an iron plate, which is united, by means of a joint or hinge, to a corresponding plate, between which the button is strongly pressed. These moulds, of which a great number is provided, are put into a kind of oven or furnace, till they acquire a temperature somewhat higher than that of boiling water; a piece of horn is then placed upon each impression in the mould; which is closed, and kept in a small screw press for a few minutes till the horn is softened. The mould is then subjected to very strong pressure, during which the pattern is communicated from the die to the horn; and in this state it is kept till it is cool, which requires about 20 minutes, otherwise the horn would be apt to return to its original form.

The holes in buttons without shanks, or what are called sailors buttons, are made by means of spindles, to which drilling instruments are attached; to these drills the button, held fast, is presented in the lathe, and the perforations are instantly completed. These spindles are so contrived, that they can be placed at different distances to answer larger or smaller buttons. But when a shank is attached to horn buttons a small hole is drilled in the horn to receive it, and a cavity being left in the mould to admit the shank, the softened horn is so firmly closed around it by the pressure, that when it cools and becomes hard it is completely secured. Sometimes ornamental figures are formed on the surface of plain horn buttons by means of a thin brass plate, out of which a pattern is cut. The plate is applied to the surface of the button, and the uncovered parts of the surface being rubbed with emery powder present a rough appearance, while those parts which are protected by the brass retain a fine black polish.

Dressing the edges.—The edges of horn buttons which project beyond the cavity of the die in the pressure, are cut off by means of shears, and filed smooth and round in a lathe, which is so constructed that two spindles, furnished with chucks, having a cavity in each for admitting the button, are brought close together and hold the button firm between them, while they are turned with the same degree of velocity, and the operation of filing and polishing the edge is performed.

Metal buttons.—Metallic substances are more generally employed in the fabrication of buttons, some of which are made by casting them in moulds, and others are formed of single pieces cut out of plates. Those of the first description are made of brass, pewter, or some other cheap alloy. Patterns are then prepared of the form of the button required, and they are connected together by small bars, so that the whole are in the same plane. The patterns thus connected vary in number from four to twelve dozen. An impression of these patterns is then taken in sand, a shank is introduced into the centre of each impression, and the whole are filled with the fused metal, which is usually a mixture of brass and tin, to which sometimes a small portion of zinc is added, for the purpose of making the metal flow freely, and producing a sharp impression. The metal being cooled, the buttons are taken from the moulds, cleaned from the sand by brushing, and carried to the lathe, where the edges are rounded and smoothed by filing. A third person is employed in smoothing the back of the button and turning the projecting part of the shank. This operation is also performed in the lathe, as well as that of smoothing the face of the button, which is executed by a fourth person.

The next operation is that of polishing, which is generally performed by women. The shank of the button being secured, the face is rubbed on a board, covered with leather, and spread with powder of rotten stone; in a second polishing a finer powder is employed; and the last polish is given by holding the button lightly to a circular board, which

Button-making.

is covered with soft leather spread over with the finest powder of the same materials as are used in the first polishings. This board is moved by the lathe.

The last operation in the manufacture of buttons of this description is boiling or washing, for the purpose of communicating a purer white to the polished surface. This process is performed by boiling a quantity of granulated tin in a solution of cream of tartar; a portion of the tin is thus dissolved, and the buttons, arranged on a grating of wire, being immersed in the solution, their surface is covered with a thin layer or wash of the metal, which improves their whiteness, while the polish remains uninjured.

Plated buttons.—In the fabrication of plated buttons, copperplates, covered on one side with silver, are previously prepared, and reduced to the proper thickness in a flatting mill. Circular pieces are the ncut out of the plate, by stamping, by means of a fly-press. In this operation the copper side of the plate is placed upwards, and the hole through which they are stamped is somewhat chamfered at the edge, for the purpose of turning the silver plate over the edge of the button. These circular pieces, which are technically called *blanks*, are introduced into a furnace to undergo the process of annealing, by which they are softened and rendered fit for bearing the operation of stamping, which is performed by means of a machine which operates in the manner of the pile-engine. The striking part of this machine, which is from one to two hundred weight, is grooved on the edges, and the grooves exactly fit the projecting parts of two strong pillars, which are placed perpendicularly, that the surface of the plate or button, which is placed horizontally, may be fairly struck. The stamp or die, which gives the form or impression to the blank or button, is fixed in the centre of the moveable or striking part of the machine, and the plate or button is placed on the fixed or lower part. The striking part is raised by means of a pulley and strong rope, which the workman moves partly with his hands and partly with one foot, which is placed in a stirrup attached to the end of the rope. In this way he raises the weight with a sudden dexterous jerk; and when it is sufficiently elevated, he lets it go as suddenly, when it falls on the plate or button, and communicates the form or impression of the stamp or die which is employed. When any impression is to be given to a plated button, after the shank has been attached to it, the shank is introduced into a cavity, formed by two pieces of steel, which, when united together, are of a conical form, and the top is convex, to correspond with the concave back of the button which is placed upon it to receive the impression.

The blanks for plated buttons being cut out and stamped, have the shanks soldered on; and this operation is performed on each button individually by means of the flame of a lamp, the heat of which is increased by the blow-pipe urged by bellows. Silver solder is employed for this purpose. For plain plated buttons, the next operation, after the shanks are soldered on, is to smooth the edges, which is done with a file in the lathe, observing the precaution of not continuing the application of the file so long as to remove the silver, which is turned over the edge. To clean the backs, the buttons are dipped in acid; and to whiten them they are boiled in cream-of-tartar and silver. The backs of the buttons are then brushed clean while they revolve in the lathe; after which they are subjected to the operation of burnishing. This is also performed in the lathe, which is then moved with great velocity. The burnishing substance, which is called by the workmen a blood-stone, and is an ore of iron, is fixed in the handle; and being dipped in water, is applied to the surface of the button, to which it instantaneously communicates a fine polish. But to render the polish still more perfect, a stone of the same kind of a finer quality is employed, and this finishes the operation.

When an impression is to be given to the surface of a button, a die, on which the intended impression is cut, is fixed in the upper or moveable part of the machine in the manner already described. But, before the blank is fixed in the machine to receive the impression, a circular piece of paper of the same size is perforated by the shank, and brought in close contact with the back. This paper is found useful in making the impression of the die sharper, and giving a dead appearance to the back of the button, when a fine polish is not required. The projecting edges are removed exactly in the same way as in cutting out the blanks, and the fileing and smoothing of the edges are performed in the lathe, as already described.

Gilt buttons.—The blanks for gilt buttons are cut out from copper, exactly in the same way as for buttons of the former description. The circular pieces are then stamped to give them a slight convexity that the buttons may not adhere together in the process of gilding. The soldering of the shanks is executed in a different manner from that of the former kind of buttons. Each blank is furnished with a small spring, which holds the shank down upon it in the proper place. A small portion of spelter and borax, mixed with water, is placed round each shank, and ten or twelve dozen of buttons being thus prepared, are placed on a flat iron plate which is introduced into an oven, the temperature of which is sufficient to fuse the solder; when this is observed, they are withdrawn from the oven, and while they are yet warm, they are thrown into a liquor which is called pickle, and is composed of water with the addition of aquafortis, or weak nitric acid of the shops. By the action of theacid, the surface becomes black, and the edges of the buttons are then filed and smoothed in the lathe. They are dipped in a second pickle more diluted with water, by which the surface is cleaned, and after being burnished in the lathe, they are ready for the process of gilding.

Gilding.—That quantity of gold which is to be applied to a certain number of buttons, which is astonishingly small, five grains being fixed by the statute for gilding 12 dozen of buttons of one inch diameter, is put into an iron ladle with a small quantity of quicksilver, and exposed to heat till the metals are united. The proper number of buttons is then in-

Button-making.

troduced into an earthen pan, and the amalgam of gold and mercury is put into the pan, with as much aquafortis diluted with water as is sufficient to moisten the whole; they are then stirred up with a brush till the amalgam come in contact with every part of the surface of the buttons, when they become white with the covering of the mercury and gold. This process is technically called *quicking*.

Drying off.—The next object of the manufacturer is to separate the mercury, that the gold may remain as a covering to the button. This process, which is called *drying off*, is accomplished by putting the buttons into a flat iron pan, which is constantly shaken over a fire to communicate an equal degree of heat, and the operation is continued till the mercury have the appearance of melting. The buttons are then introduced into a felt cap, and stirred about with a brush that the amalgam of gold and mercury may be equally spread over their surface, while the mercury is at that temperature which nearly renders it volatile. The buttons being returned to the pan, the increased heat drives off the mercury in the state of vapour, and the yellow colour of the gold begins to appear on the surface. The same processes are repeated a second time, and if afterwards any white spots should remain, the buttons are put into a cylindrical copper box with a lid, and thus being turned round on a charcoal fire to heat all the parts equally, the remaining mercury is separated, and the gilding process is now completed; all that remains is to burnish the buttons by the same operations as have been already described in finishing plated buttons. In some cases the buttons are double and treble gilt, and this is done by repeating the different processes.

In the common mode of drying off, the mercury which is employed in the gilding process is not only lost, but the workmen are exposed to its fumes, which are extremely noxious. To preserve the mercury, and at the same time to secure the operator from the vapour, an apparatus has been contrived by Mr Sanders, a button manufacturer at Birmingham. A kind of furnace or oven, the bottom of which is an iron plate, is constructed over a hearth or fire-place; the front part of it is covered with glass, that the workmen may see the operation, and the glass comes down so low as just to leave room for moving the pan in which the buttons are heated. From the top of this oven proceeds a tube, which terminates in a tub of water in which the mercury which flies off is condensed; and in case any of the mercury should remain uncondensed, another tube proceeds from the first tub, which is closely shut, to another placed on the outside of the building. In this way the whole of the mercury is collected, without any inconvenience to the workmen.—*Phil. Mag*. vol. ix.

Gilt Buttons are sometimes milled on the edge, which is executed by a machine similar to that which is used for milling the edge of coins; and some buttons of the same description are ornamented with concentric circles. This operation is executed with a milling tool, which is a small steel roller, on the circumference of which the pattern required is cut; the operation is performed in the lathe, and the milling instrument is held in a slide-rest, that circles of the same diameter may be formed on all the buttons.

Buxton.

BUXTON, a village of Derbyshire, in England, which has been long celebrated for its mineral waters, and, from the remains of an ancient bath, and various roads which lead to this spot, seems to have been known to the Romans. But its mineral springs seem to have been forgotten till after the middle of the 16th century, when they were brought into notice by a treatise which was published, recommending their use as a cure for different diseases. The surrounding country, which is remarkable for its nakedness and sterility, renders the approach to Buxton, and the first view of the town, extremely striking to the traveller, and particularly the magnificent range of buildings erected by the duke of Devonshire, in the form of a crescent, and at an expence of L.120,000. In these buildings are three hotels, and some private lodging-houses, and the front is adorned with a splendid colonnade.

The population of Buxton is about 800, and it is supposed that not fewer than 500 persons, including their attendants, visit it annually on account of the waters. The manufactures are limited to a few cotton stuffs; for the principal support of the place depends on the strangers during the bathing season, which continues from June to October. The company are amused with assemblies and plays.

Buxton has the advantage of both cold and hot springs; the water is impregnated with lime in different states of combination, common salt, and a portion of azotic gas. The temperature of the hot spring is about 82° of Fahrenheit. Commodious places are fitted up both for bathing and drinking the waters.

Byrom || Byron.

BYROM, JOHN, the author of some fugitive poetry, was a native of Manchester, and was born about the year 1691, but few records of his life have been preserved. He contributed to the Spectator two humorous letters on dreams, and a poetical production which begins,

"My time, O! ye muses, was happily spent,"

all of which are in the 8th volume of that work. But he is best known as the author of an elegant system of short-hand, the teaching of which was his chief support, till he came to the possession of an estate by the death of an elder brother. He died in 1763; and a collection of his poems, in two volumes octavo, was published at Manchester in 1773.

BYRON, the HON. JOHN, was the fourth son of Lord Byron, and was born in 1723. In early life he entered the British navy, and was a lieutenant on board the Wager, one of the ships which accompanied commodore Anson in his expedition against the Spanish settlements in South America in 1740; but being wrecked on the coast of Patagonia, became the subject of his celebrated narrative, which, in the detail of the dangers, sufferings, and adventures in which he was concerned for five years, is unrivalled for the deep interest which it excites in the mind of the reader. Mr Byron, after his return to Britain, rose through the different gradations of the service to the rank of admiral, but was remarkable through

Byssus. life for the ill success which almost invariably accompanied all his services. He died in 1786.

BYSSUS, a fibrous matter mentioned by the ancients, and said to have been produced in India, Egypt, and some parts of Greece, and employed in the fabrication of the finest kinds of cloth, particularly for the garments which were worn by the Jewish and Egyptian priests. The Greek word which is met with both in the Old and New Testament, is rendered by some interpreters *fine linen*, and by others *silk*. Among the conjectures concerning the nature of the ancient Byssus, it is supposed to have been a fine kind of flax, cotton, a mixture of flax and cotton, or the silky matter of the *pinna*, a genus of bivalve shell-fish, some species of which are found on the shores of the Mediterranean.

BYZANTIUM, an ancient city of Thrace, situated on the Bosphorus, was founded, according to some, about the time that Tullus Hostilius reigned in Rome; but according to others, in the time of the Argonauts, by Bysas, a king of the surrounding territory, and from whom the city derived its name. The history of this city is closely connected with Roman affairs. It became a province subject to Rome the year after Jerusalem was destroyed by Titus; and, after various fortunes, it came under the dominion of Constantine the Great, about the year 323. Enlarged and beautified by this emperor, and enjoying all the immunities and privileges of the metropolis, it became the place of his residence, and at last received the honour of his name, from which time it has been called Constantinople, or the city of Constantine. Byzantium.

C.

Caaba. C is the third letter, and the second consonant of the alphabet, formed, according to some, from the Greek letter, and, according to others, from the Hebrew, the form of which approaches more nearly to the modern letter. Before the vowels a, o, and u, it is sounded hard like k, and before e, i, and y, like s. In some ancient inscriptions the Greek letter s, has the same form as our c. In abbreviations C stands for Caius, Carolus, Cæsar, *condemno*, &c. and CC. for *consulibus*. As a numeral, C denotes one hundred, CC, two hundred, &c.

CAABA, in its proper signification, denotes a square stone building, but is particularly applied by the Mahometans to the temple at Mecca, to which the followers of the prophet assign a very high degree of antiquity, supposing that it was built by Adam after he was driven from paradise, according to a design of a celestial temple which the Almighty let down from heaven, and placed in Mecca. Being destroyed by the deluge, it was rebuilt on the same spot by Abraham and Ishmael his son. Long before the time of Mahomet, this temple was a place of Pagan worship, and was greatly celebrated for sanctity. It is said to have contained 360 different images, corresponding to the number of days of the Arabian year. When Mahomet declared himself a prophet, and became at the same time a temporal prince, he seized this temple, destroyed all the images, and appointed it to be the chief place of worship for all true believers. In a corner next the east door, a black stone is deposited, and is highly venerated among the Mahometans. According to the tradition, it was brought down from heaven by the angel Gabriel at the creation of the world, and was originally of a white colour, but had contracted its blackness from the guilt of the sins committed by mankind. It is now enclosed in silver, is called by some the right hand of God, and is most devoutly kissed by pilgrims who visit Mecca.

The Caaba has a double roof, which is supported within by three octagonal pillars of aloes wood, and between them are suspended silver lamps from a bar of iron. The outside is covered with rich black damask, which is adorned with a band of gold embroidery. This temple is surrounded by two inclosures, and it enjoys the privilege of an asylum for criminals. Cabal || Cabot.

CABAL, the celebrated name of the ministers of Charles II., the first letters of whose names, Clifford, Ashley, Buckingham, Arlington, and Lauderdale, compose the word, which has been applied to associations formed for the purpose of contriving or executing illegal measures.

CABBALA, a word used by the Jews to denote those traditions relative to the interpretation of the law which they say were at first communicated by revelation, and have been transmitted unchanged from generation to generation. These traditions have been termed the oral law, in opposition to the written law. Another cabbala is called artificial, and consists in searching for abstruse and mysterious meanings of a word in scripture, from which certain explanations are borrowed, by certain combinations of the letters of which it is composed. This cabbala is divided into three kinds; in the first, the letters of a Hebrew word are taken for ciphers or arithmetical numbers, and every word is explained by the arithmetic value of the letters which enter into its composition; in the second kind, every particular letter of a word is taken for an entire diction; and in the third, different transpositions or changes of the letters are adopted. Those who profess the study of the cabbala are distinguished by the name of cabbalists, and they suppose that there is not a word, letter, or accent in the words of their law which contains not some mystery.

CABIRI, in ancient mythology, were certain divinities worshipped in some parts of Greece; and Cabiria were the festivals which were celebrated in their honour, with great solemnity, in Thebes, Lemnos, and Samo-Thracia.

CABLE, a thick strong rope which is employed for securing a ship at anchor. See Rope-making.

CABOT, Sebastian, a celebrated navigator, is supposed to have been born at Bristol, about the year 1477, where his father, a Venetian, had settled as a merchant and pilot, under the patronage of Henry VII. The father had received a commission from the king of England to undertake a voyage of discovery; he was accompanied by his son in his 20th year; and in this voyage Newfoundland was discovered. In the reign of Henry VIII. Sebastian Cabot sailed from England for the purpose of discovering a passage to the East Indies, which was then the favourite object of pursuit; but being disappointed in this attempt, he sailed to the southward, touched the coast of Brazil, and having traded for some time at Hispaniola and Porto-Rico, he returned to England. Having removed to Spain, he was appointed to an official situation, and constituted inspector of projects of discovery. Engaged by a company of Spanish merchants to undertake an expedition to the Moluccas or Spice islands by the straits of Magellan, he sailed from Cadiz in 1525, with four ships, and having reached the coast of South America, he was disappointed of the distant objects of the voyage by a mutiny of his crew and the want of provisions. He then sailed up the river La Plata, made various discoveries, and built a fort to overawe the natives. In the hope of being able to keep possession of the country, he dispatched a ship to Spain, and demanded a supply of provisions, ammunition, and troops, from his employers; but they did not support his plans; and having returned to Spain after six years absence, he met with no very cordial reception.

Returning to England about the end of the reign of Henry VIII. he was appointed grand pilot, with a handsome salary, was in great favour with Edward VI. and an expedition was fitted out under his auspices, for the purpose of exploring the north-east coast of Europe. This venerable navigator died in 1557, at the age of 80. Cabot is said to have been the first who discovered the variation of the compass, and he was eminently distinguished by his noble enthusiasm, bold enterprise, and professional skill.

CABUL, or KABOUL, a large province of Afghanistan, which lies between the 33° and 35° of north latitude, is about 250 miles long, and 150 miles broad, is greatly diversified by snowy mountains, hills of moderate elevation, and extensive plains and forests. Some parts of the province are traversed by considerable rivers, of which Cabul, called also in some parts of its course Attocka, and Cow or Cowmull are the chief. The principal towns are Cabul and Peshawer; the central districts near the capital receive sugar and cotton cloths from Peshawer, which they exchange for iron, leather, and tobacco; and the same commodities, with lamp-oil, are exported to Candahar, for which the returns are made in the manufactures of Persia and Europe. Horses, furs, and hides, are brought to Cabul from Bocharia. The Afghans, who inhabit this province, are a rude and savage race, one tribe of whom dwell in caves, and live by plunder.

In 1809 an embassy was sent from the British government in India to the sovereign of this country, and an alliance was entered into, in which it was agreed that the armies of the Cabul state should oppose the progress of the French and Persians, in case they should attempt a passage to the British settlements, and the expences were to be defrayed by the British state.

CABUL, the capital of the province of Cabul in Afghanistan, stands in a spacious plain, which is well watered by the Cabul and other rivers, and interspersed with walled villages. The city is surrounded by a wall about a mile and a half in circumference, and the houses are built of rough stones, clay, and unburnt bricks. The surrounding territory is occupied by gardens, and excellent fruits are abundant; the great Bazar, or market-place, is frequently crowded with Usbeck Tartars, whose features resemble the Chinese and Malays. The city is also frequented by many Hindoo merchants, who are protected by the government, and contribute greatly to its prosperity. Cabul is 839 miles distant from Delhi, and 1815 miles from Calcutta.

CACHAO, a province and city of Tonquin in Asia. The city, which was formerly the capital of the empire, and the residence of the sovereign, is without walls or fortifications; the streets are generally narrow, and the houses, which are built of wood and clay, are not more than one story in height. The pagodas or temples are on a larger scale, and are not destitute of grandeur. The palace in the centre of the city is an immense pile of building, and, including the gardens, is encompassed with a wall, which comprehends a space three leagues in circumference. That part of the palace destined for the residence of the monarch was adorned with numerous columns of a beautiful kind of wood, with a profusion of gilding; but in some late wars it was reduced to ruins. The population of this city is stated at 40,000; and, from the establishment of an English and Danish factory, it appears that it has some commercial intercourse with Europeans.

CACTUS, a genus of plants belonging to the Icosandria class, and of which some species are not less remarkable for their curious structure, than for their valuable productions. On one species the cochineal insect, of so much importance in the arts, is produced.

CADI, a judge of civil affairs among the Turks, and is generally applied to those who are appointed to decide in such matters in towns.

CADIZ, a city and sea-port of Andalusia in Spain, is about 60 miles S. W. from Seville, and 40 miles N. W. from Gibraltar. It occupies the western extremity of the isle of Leon, and communicates with the land by means of a causeway. It is strongly fortified on all sides, the streets are regularly arranged, though some of them are narrow, and the houses are well-built. Some of the squares are very spacious, and the ramparts afford a delightful walk, and an extensive and diversified prospect. Some of the public buildings are magnificent structures, and some of the churches are adorned with paintings by the first masters, while some of the private citizens can boast of a numerous and splendid collection of the most admired productions of the pencil. The bay of Cadiz, which is about ten leagues in circumference, affords excellent anchorage ground for ships, which are protected on all sides, except the west, where it opens toward the Atlantic, and the entrance is strongly defended by forts. Cadiz has a royal dock-yard, and extensive magazines for all kinds of naval stores. Beside the usual institutions for the ordinary branches of education, academies have been established for those departments of knowledge which are more immediately connected with naval and military affairs.

The population of Cadiz has been variously stated, at 65,000, 70,000, and even at more than 80,000. The tunny fishery, which commences in May, and continues till the middle of June, is the source of a considerable trade between Cadiz and the ports in the Mediterranean and other parts of Europe. The manufactures of this place, which extend only to ribbons, some silk stuffs, and a few linens, are scarcely worthy of notice; but to foreign commerce, and especially to the trade with the American colonies, Cadiz is indebted for its wealth and prosperity. At one period of its history, all the manufactures of the kingdom, destined for the supply of the Spanish colonies, were transmitted through Cadiz; and all the productions of the new world were received into its port in return. But this trade is now shared by other cities of Spain. The trade of Cadiz with European nations, is also valuable and extensive; and many foreigners have factories and resident agents to conduct their business.

CADMUS, in fabulous history, was the son of Agenor king of Phœnicia, and the brother of Europa, who was carried off by Jupiter. Being dispatched by his father in search of his sister, and being disappointed in recovering her, he dared not return to his own country. After various adventures he built Thebes; and he and his wife Hermione, whom he had received from the gods, were changed into serpents. Attempts have been made, by learned antiquaries, to trace the foundation of this fabulous story to some events in real history, for which the reader may consult the works of Bochart and Bryant. To Cadmus is ascribed the introduction of letters into Greece: and hence these letters, which are sixteen in number, are called Cadmean letters.

CADUCEUS, the rod or sceptre of Mercury, which, according to the fable, he received from Apollo, and consists of two serpents twisted together. Great powers are ascribed to this rod by the poets, and among the ancients it was the symbol of peace.

CAEN, a city of Lower Normandy, and capital of the department of Calvados in France, stands in a rich valley at the confluence of the rivers Orne and Odon, is surrounded with walls and defended by a strong castle. Some of the squares are spacious, and adorned with fine houses. The abbey of St Stephen, which is said to have been built by William the Conqueror, is memorable as the repository of the remains of that monarch; the university of Caen, which has been in considerable celebrity, was founded in the fifteenth century by Henry VI. of England.

The population is estimated at 36,000, and the inhabitants are much employed in the manufactures of woollen and cotton stuffs, hosiery, laces, iron ware, and porcelain. The river Orne, which is navigable, affords great facilities for commercial intercourse, both with other parts of France and with foreign countries. At an annual fair, which is crowded with merchants from all quarters, a very active trade is carried on for fifteen days.

CAERFILLY, a small town of Glamorganshire in South Wales, which is chiefly remarkable as a place of high antiquity, and for the ruins of a castle of great magnitude. Many Roman coins are found in the vicinity. The castle is supposed to have been erected about the end of the eleventh century; and the few inhabitants of the place are chiefly employed in the manufacture of pig and bar iron, stockings, and blankets.

CAERLEON, a small town of Monmouthshire, which stands on the banks of the river Uske, and from the numerous remains of altars, pavements, statues, and inscriptions, seems to have been a place of great importance in the time of the Romans. From the early descriptions of this place, it appears that it was greatly distinguished by the splendid palaces and stately edifices which were constructed by the Roman princes; and it was furnished with baths, temples, and theatres, the remains of which exhibit striking proofs of Roman magnificence. The number of inhabitants scarcely exceeds 700, and they are chiefly employed in the tin-works for the manufacture of tin-plates.

CAERMARTHENSHIRE, a county of South Wales, having St George's Channel and Pembrokeshire on the south and west, and the counties of Cardigan, Brecknock, and Glamorgan on the north and east, presents in general a hilly aspect, and on the north and east rises into a mountainous elevation. It is intersected with numerous narrow vallies, and the vale of Towy, 30 miles in length, is celebrated for its picturesque scenery, some parts of which, as Grongar hill, have obtained classical fame. The Towy, the Taw, the Cothy, the Dulas, and the Gwilly, are the principal rivers, some of which abound with trout and salmon. Limestone is abundant, and mines of lead, iron, and coal, furnish employment to a great number of the inhabitants. The soil in some places is very fertile, and yields sufficient crops of oats to admit of some exportation; the more elevated tracts yield excellent pasturage, and a good deal of the produce of the dairy is exported. The number of inhabitants exceeded 67,000 in 1801, and had increased to more than 77,000 in 1811. Remains of ancient roads and camps, and numerous silver coins, which have been discovered in different places, shew that this country was occupied by the Romans.

CAERMARTHEN, Town of, the capital of the county of the same name in South Wales, stands in a rich valley on the north side of the river Towy, consists of numerous streets, and contains many well built modern houses. In ancient times it was defended by walls and a strong castle. The number of inhabitants in 1811 exceeded 7000. Tin-plate and cast-iron are the chief manufactures, which, with rope-making and ship-building, furnish the chief employment to the inhabitants. Caermarthen is about eight miles from the sea, but the navigable river admits vessels of about 100 tons burthen, and affords the means of carrying on a considerable coasting trade. This town is memorable as the birth-place of Merlin Ambrose, the famous conjurer or magician, and Merlin's grove, and a rock called Merlin's chair, are still pointed out.

CAERNARVONSHIRE, a county of North Wales, has for its boundary on the east Denbighshire, and the sea on all other sides, is remarkable for its mountainous scenery, in which the lofty Snowdon is most conspicuous. Three ranges of mountains, divided by fertile vallies, traverse the county, and the more elevated range is covered with snow during a considerable part of the year. Snowdon rises to the height of more than 3500 feet above the level of the sea, and the height of the stupendous promontory of Penmaenmaur is about 1550 feet. The principal rivers are the Conway and Seiont; the first rising in a lake proceeds in a northerly course to the Irish sea, and the last having its source among the mountains around Snowdon, falls into the straits Menai, at the town of Caernarvon. The strata of this country belong to the primitive class of rocks, and are chiefly composed of granite, micaceous, and burgelaceous schistuses, of which the latter furnishes immense quantities of roof slate for exportation. Lead and copper mines have also been wrought in the mountains.

The extent of this county is estimated at 45 miles in length, and 12 or 14 in breadth, and, with a surface of more than 300,000 acres, little more than one-half is fit for cultivation, or even pasture land. The population in 1801 was stated at 41,521, and had increased to more than 49,000 in 1811. The county is divided into ten hundreds and 71 parishes. Bangor and Caernarvon are the chief towns. The shores abound with fish, particularly with herrings, lobsters, and oysters. Grain is cultivated in the vallies and flat districts near the sea; and oats and barley, with the produce of the dairy, and black cattle, are exported. A bold undertaking, of recovering between three and four thousand acres of land from the sea, at the bottom of the bay of Cardigan, commenced about the year 1808. The embankment constructed for this purpose is twelve yards wide at the top; and to prevent the materials of which it is composed from sinking into loose sand, a thick matting of rushes, secured by stakes, was laid.

CAERNARVON, town of, the capital of the county of the same name in North Wales, occupies a pleasant situation, which is nearly peninsular, opposite to the isle of Anglesea; consists of regular streets and well-built houses, contains about four thousand inhabitants, and has a considerable trade with the chief ports of England and some parts of Ireland. The ruins still visible, indicate that it was once a Roman station; and a strong castle, with many towers, shews that it was a place of great importance in the early period of English history. Caernarvon is much resorted to in summer for sea-bathing. Visitants have the advantage of hot and cold baths, and the vicinity affords delightful walks and highly picturesque scenery.

CAERWYS, a town of Flintshire, which seems to have been once a Roman station, and was memorable at a later period for an annual meeting of bards and minstrels, which becoming a lawless scene of tumult and disorder, was suppressed in the time of queen Elizabeth. This place was also at one time famous for its fairs of cattle, sheep, and horses; but the population is now under 800, and no activity or industry promises to revive its declining fortunes.

CÆSALPINIA, a genus of plants belonging to the Decandria class, and of which one species, the Brazil-wood, is much employed as a dye-stuff. See Botany.

CÆSALPINUS, Andrew, a celebrated Italian naturalist and physician, was born at Arezzo in Tuscany, in 1519. Of his early education scarcely any thing is known; but such was his reputation for medical knowledge, that he was appointed physician to the pope, which situation he held during the latter years of his life. His studies were directed to the philosophy of the times, as well as to those branches of knowledge more immediately connected with his own profession. But he is most celebrated as the author of a treatise on botany, which was published at Florence in 1583, and is the first attempt of the systematical arrangement of plants. He also published a treatise on metallic substances; and he died at Rome in 1603, when he had reached the venerable age of 84.

CÆSAR, Caius Julius, the first Roman emperor, and one of the most conspicuous characters in Roman history, was descended of the Julian family, which boasted of high antiquity, and at last became illustrious by the splendid panegyrics of the orators and poets of the classic age of Augustus, who were anxious to secure the favour of that monarch. The early youth of Cæsar was distinguished by profligacy; but even then his aspiring ambition was not overlooked. When he was only in his 17th year, he was chosen priest of Jupiter. To follow out his ambitious views, he spared no expence in cultivating the favour of the people, by the exhibition of all kinds of public entertainments. After a severe struggle with some persons of the highest influence, he succeeded among powerful competitors to be elected high priest. He rose afterwards to the office of prætor; and on the expiry of his office he was appointed to the government of Lusitania. The next step to power was the consulship, which he obtained chiefly through the influence of Pompey and Crassus, of the rivalship between whom he had the address to effect a temporary cessation; and to secure more strongly the friendship and influence of Pompey, he gave him his daughter Julia in marriage, while he indulged the vanity and avarice of Crassus by granting him a lucrative appointment. The campaigns of Cæsar in Gaul gave high celebrity to his military reputation, and led the way to the unbounded power at which he aspired. With an army devoted to his interests at his command, Cæsar had renewed his alliance with Pompey and Crassus, and with these powerful men had formed a plan for the partition of the empire. But during his first expedition to Britain, his daughter Julia, the wife of Pompey, died; and from this time, it would appear, Pompey and Cæsar began each to consult his own individual interests.

The intrigues and violence of parties produced great disturbances in Rome; the appointment of a dictator was proposed to suppress the outrages; and Cæsar, during his absence, was nominated by his friends to the consulship. This was the commencement of the severe struggle between Pompey and Cæsar, in which the latter was successful, and finally triumphed over his rival, whom he defeated in the battle of Pharsalia. Pompey fled to Egypt, where he was followed by Cæsar, but he had previously fallen by hands of assassins. Cato, with the fleet and the remains of the army, directed his course to the Roman province of Africa, and with the assistance of Juba, the king of Numidia, seemed still able to make a formidable resistance; but he was at last defeated, and seeing no hope of resisting the power of Cæsar, he resolved by a voluntary death to secure himself from being the victim of his ambition.

Cæsar was now in reality the ruler of the empire; he received every mark of servility from the senate and people at Rome, whom he amused with the most expensive and most magnificent entertainments. On one occasion a crown was offered him; but no marks of applause having followed from the people, he pushed it away with his hand. A conspiracy was at last formed against his life, and he fell in the senate-house, at the foot of Pompey's statue, being pierced with 23 wounds. Of the military career of this extraordinary man, the best record is to be found in his Commentaries, composed by himself, and remarkable for simplicity and purity of style; and the political events in which he was concerned form a striking feature in that period of Roman history.

CAFFA, or KAFFA, which is supposed by some to be the ancient Theodosia, is a sea-port town of the Crimea, and is situated on an elevated spot, which forms an amphitheatre round a spacious bay. For several centuries after the 13th, when it fell into the hands of the Genoese, it enjoyed a large share of commercial prosperity; but its trade afterwards declined, and it is now reduced from a crowded population to about 100 houses. Caffa, with the rest of the Crimea, came under the dominion of the Russians in 1783.

CAFFRARIA, an extensive region of Southern Africa, which lies between the 20° and 25° of south latitude on the west, and between the 24° and 32° on its eastern boundary. The country towards the east is rich and fertile, the mountains are clothed with forests, and the plains are well watered by numerous streams, and produce a luxuriant vegetation; but the western districts present nothing but a perfect desert. This country has been rarely visited by Europeans. The general denomination of the inhabitants is Caffres, and they are quite distinct in their appearance and character from the Hottentots on the south, and the negro tribes on the north. They are governed by independent chiefs, who, by a kind of tacit consent, it is said, acknowledge one as their sovereign. Agriculture is not very extensively practised, for their chief wealth consists in cattle. Considerable towns have been discovered in some parts of this country, and particularly the town Leetakoo, which was visited in 1801 by commissioners appointed by the colonial government at the Cape, and more lately by Mr Campbell, a missionary traveller. See Barrow's *Travels in Southern Africa*, and Campbell's *Travels.*

CAGLIARI, the capital of the island of Sardinia, stands on the southern side of the island, and at the bottom of a spacious bay, from which it exhibits a picturesque appearance on its elevated situation. It is defended by a castle and fortifications, and is divided into the upper and lower town. The cathedral is a magnificent edifice, besides which there are numerous churches and convents. The population is estimated at 30,000. But, with the advantage of an excellent harbour, the trade is said to be extremely limited.

CAHORS, the chief town of the department of Lot, in France, occupies a peninsular spot formed by the river Lot, is irregularly built, with narrow streets, and is fortified with strong walls. The remains of Roman architecture are still visible in the neighbourhood. The cathedral is an ancient structure, adorned with a cupola. The university, which was founded in the beginning of the 14th century, was incorporated with that of Toulouse in the middle of the 18th, but an academy and lyceum still exist.

The population is estimated at 12,000. Some kinds of woollen stuffs are manufactured; but the chief source of the trade of Cahors is in the produce of the vineyards of the surrounding country. The wine is highly esteemed, and a great quantity is carried down the river to Bourdeaux for exportation.

CAIFA, or CAIPHA, a sea-port town of Palestine, at the foot of mount Carmel, and separated from Acre by the bay of the same name. The houses are small, flat-roofed, and irregularly distributed. The trade of this place has increased since that of Acre, in consequence of its port being choked up, has declined. The inhabitants are chiefly Mahometans, Catholics, and Greeks; and the pilgrims who visit the church upon mount Carmel are subjected to a certain tribute. Caifa is eight miles south-west from Acre.

CAIMAN, or CAYMAN ISLANDS, are two small islands which lie to the north-west of Jamaica, on one of which, called the Great Cayman, a few inhabitants reside, and are chiefly occupied in the turtle fishery, from which the markets of Jamaica, and ships on their homeward-bound voyage, which touch at these islands, are supplied with turtle.

CAIRN, is a collection of stones thrown together in a conical form, and common in many parts of the world, particularly in Scotland and Wales. Cairns are distinguished from barrows, from the first being composed of stones, and the last of earth; but whatever were the materials, the original object of these structures seems to have been for a memorial of remarkable events. They were afterwards employed as places of sepulture for distinguished persons, and in some cases they seem to have been intended for religious purposes, or as a kind of rude temple. In some of these cairns which have been examined in Scotland, nothing different from the stones of which they are composed was found, from which it would appear that they were intended as monuments of some remarkable event; but, in other cases, warlike instruments, ornaments of dress, and urns containing ashes, sufficiently indicate that they are the tombs of celebrated warriors. The magnitude of the tumulus, or cairn, was regarded as a mark of respect, and hence the proverb, "I will add a stone to your cairn," which is still prevalent among the Highlanders of

Cairo. Scotland, is considered as an expression of regard to the memory of the dead. But among the same people it is not unusual for the passing traveller to add a stone to the heap which is intended as a memorial of the spot where a murder has been committed, or some disastrous calamity has happened.

CAIRO, or GRAND CAIRO, and sometimes called the Queen of Cities, stands on the eastern bank of the Nile, a little above the Delta, or plain of Lower Egypt. It was founded in the 10th century, according to oriental writers, and received its present name, which signifies Victorious, from Moaz, the first caliph, in memory of his conquest of Egypt, Having transferred the seat of empire from Barbary to Fostat, the capital of Egypt, he erected a splendid palace in its neighbourhood; but two centuries elapsed before Cairo could boast of any thing more than being the residence of the sovereign and his attendants, and a station for his soldiers. On the invasion of Egypt by the Christians in the time of the Crusades, the capital Fostat was reduced to ashes, to disappoint them of their expected booty; and the inhabitants who survived the calamity sought an asylum in Cairo, which from that period became the capital. Cairo was enlarged, adorned, and fortified, by the famous emperor Saladin. It was in the height of its prosperity about the commencement of the 15th century; was then a central position for the trade of Europe and Asia, and was still respectable for men of learning. But the conquest of Egypt by the Turks, and the discovery of a passage to India by the Cape of Good Hope, threw this flourishing trade into a different channel, and caused the decline of this rich city.

Cairo, which is still a large city, is described as being equal in extent to Paris. Arranged in somewhat of a crescent form, it is more than nine miles in circumference, and seen from the Nile, from which it is little more than a mile distant, it presents a most magnificent scene, in which the citadel, innumerable lofty edifices, and countless minarets, rising as it were from a grove adorned with the richest foliage, are the most conspicuous objects. But a nearer approach affords a less pleasing view. The streets are crooked, narrow, and unpaved; and with the crowds of men and animals, which are continually passing along, are extremely disagreeable, from the dust and filth. The houses are generally of wood, or unburnt bricks dried in the sun, and consist only of a single story; but the mansions of the grandees are large and commodious, and are constructed of a soft kind of stone. The houses are crowded together into groupes, with large intervening spaces, which, as well as the courts and gardens within the walls, are covered with water in the time of the inundation of the Nile. Among the public structures of Cairo, the reservoirs for water and the baths are remarkable for their elegance, and the warehouses for merchandise, as well as the market-places, are spacious and commodious; but the mosques, of which more than 300 are erected within the walls, form, with their numerous and lofty minarets, the chief ornament of the city. Beside the mosques, the Jews have a synagogue, and the Greeks and some other sects of Christians have also places of worship. The citadel, which is elevated on a rock, is three miles in circumference, and affords one of the most splendid views in Egypt. It includes the palace of the pacha, the barracks of the janizaries, and some remains of antiquity; among which, Joseph's well, dug to the depth of 276 feet through the solid rock, is a remarkable specimen of ancient art. The diameter of the well varies at different depths, and where it is contracted, stages are formed for oxen to drive a wheel for raising the water. A huge pile of building within the citadel is called Joseph's palace, the great hall of which, adorned with massy pillars and arches for supporting its spacious roof, has been greatly admired. Cairo.

Boulac, which is about a mile to the west of Cairo, on the right bank of the river, may be considered as its principal port, enjoyed at one time great commercial prosperity; but it suffered severely from the French, who plundered and burned it to the ground. About a mile distant also, and higher up the river, stands Fostat, formerly the capital of Egypt, and still a populous place. The great canal, which formed a communication between the Nile and the Red sea, passes off from the river near this place, and proceeding towards Cairo divides the city into two parts, and when it is filled with water supplies all the ponds and reservoirs.

On the island of Rhoda, a charming spot in the middle of the river, is erected the celebrated Mikias or Nilometer, or measurer of the Nile. The object of this structure is to ascertain the rising of the river during the annual inundation. It is composed of a magnificent marble pillar, surmounted by a Corinthian capital, which rises from the centre of a basin having a communication with the Nile, and being graduated, indicates the increase in the height of the river. A splendid dome, supported by columns, is erected over the pillar. This building is said to be nearly 1000 years old. As the fertility of the soil depends on the waters of the Nile during the inundation, great attention is paid to their increase, and the instrument is carefully watched during that season by a proper officer; and when they have risen to a sufficient height, the canal is opened with great ceremony, in presence of the beys and the whole court, and an immense concourse of the inhabitants of the city.

The population of Cairo has been variously stated at 250,000,—300,000, and even as high as 700,000; and it is composed of people of all countries and religions. All the luxurious manners and customs of eastern regions prevail among those who have it in their power to indulge in them. Sailing on the Nile is one of the great amusements of the inhabitants of Cairo, and vessels of a light construction are elegantly fitted up for these aquatic excursions.

The Turkish government is little favourable to the prosperity of the arts and manufactures. Some silk stuffs, linen cloth, the manufacture of sugar, of sal ammoniac, saltpetre, and coarse gunpowder, with glass lamps, and some kinds of leather, are all that occupy the industry of the inhabitants. The mode of hatching chickens by means of artificial heat, which has been long known in Egypt, is still practised at Cairo. This celebrated city possesses peculiar local advantages for commerce; and accordingly it has been, from the earliest times, the central emporium of trade for Europe and the western parts of Africa on the one hand, and Abyssinia, Arabia, and India, on the other. Every year a caravan arrives from Abyssinia loaded with the rich productions of the interior of Africa, and being joined by another caravan from the western parts of Africa, it proceeds towards Arabia. This perilous journey is undertaken partly for religious and partly for commercial purposes, and having performed the prescribed ceremonies at the holy city, and exchanged their merchandise for the valuable commodities of the east, the immense body of travellers, amounting, it is said, sometimes to 100,000, return from Mecca by the same route.

CAITHNESS, a county of Scotland, which has for its boundaries on the north the Pentland frith, on the east and south the German ocean, and the county of Sutherland on the west, is about 35 miles in length, and about 20 in breadth, and includes an area of nearly 700 square miles. Great part of the sea coast is rocky and indented with numerous bays. Duncan's-bay-head, which forms the north-east point of Caithness, is the most northerly promontory in Great Britain. The eastern districts of the county are level, and watered with rivers and lakes, but on the west side it is hilly and mountainous, and fit only for pasturage. The strata of Caithness are composed chiefly of primitive rocks. Some indications of iron, lead, and copper ores have been observed, but not in such abundance as to afford profit in working. Limestone and marl are abundant; but the discovery of coal has been attempted with no prospect of success. Many ancient castles still exhibit their mouldering remains in this country, and the Picts' houses, peculiar structures, somewhat of a conical form, and remarkable for the thickness of their walls, still exist to exercise the ingenuity of the antiquary.

The population of Caithness, in 1801, amounted to 22,609, and in 1811 had increased to 23,419. The improvements of agriculture have not been neglected, and excellent crops of barley and oats are obtained. A great number of cattle was annually reared and sent to the markets in the south; but sheep-farming is now more prevalent in the higher districts of the county. The herring fishery on the coast is sometimes abundant and successful, and the caverns along the shore afford opportunities of taking great number of seals. Numerous sea-fowl hatch in the rocks, and furnish a supply of food to the inhabitants from their eggs and young. The spinning of linen yarn, and the making of leather, are almost the only manufactures of the county.

CALABRIA, a district of the kingdom of Naples, which consists of two provinces, Hither and Farther Calabria, of the latter of which Reggio is the capital, and Cosensa of the former. See NAPLES.

CALAIS, a sea-port town, and chief place of a district in the department of the Straits of Calais in France, stands on marshy ground, is surrounded by a moat and wall, and is defended by a citadel. The streets are pretty regular and well paved, and the houses are well built. The arsenal, theatre, a large hotel, with some churches and monasteries, are the chief public edifices. The harbour, formed by a small stream, is greatly incommoded with sand-banks. The population is about 8000. Stockings and soap are said to be the only manufactures; but the herring, cod, and mackerel fisheries are considerable; the coasting trade is lucrative, and a great deal of business is done at the fairs in January and July, which continue each for about ten days. Calais being the thoroughfare between France and England, is a place of great resort in time of peace by the natives of both countries; and the mail is regularly conveyed twice a week between Calais and Dover.

CALAMINE, an ore of zinc, composed of oxide and carbonate of zinc. See CHEMISTRY and GEOLOGY.

CALCUTTA, the capital of Bengal and of the British territories in India, stands on the eastern branch of the Hooghly, and stretches about three miles along the river. Calcutta, comparatively a modern town, having risen to its present extent and population in the course of the 18th century, is distinguished into the Black town and that which is inhabited by Europeans. The houses of the latter are entirely of brick, covered with a peculiar kind of mortar made of shells, which has all the appearance of fine marble, are in detached situations, and have spacious and lofty apartments. In the Black town the streets are narrow and crooked, and the houses are constructed of brick, mud, or bamboos and mats. Of the public buildings, the citadel and the government-house are by far the most conspicuous. The former stands about a quarter of a mile from the city; is on a very large scale, and includes bomb-proof barracks fit to accommodate 10,000 men. The esplanade, between the city and Fort-William, is the morning and evening resort of the inhabitants, and is crowded with all ranks and descriptions of persons, who frequent it for exercise and recreation. The new government-house on the west side of the esplanade is a most magnificent edifice. To these may be added, the court-house, the Armenian, the episcopal, and presbyterian churches. Calcutta is now the see of a bishop, as well as the residence of the governor-general.

Various benevolent institutions have been established and liberally supported; among which are enumerated a free-school, schools for the education of orphans of the privates and officers in the military department of the company, and an hospital for the sick of the native inhabitants. The attempt to establish a college on the plan of similar institutions in Europe has not succeeded. All that is retained of the establishment is limited to three teachers of the native languages. This termination of the undertaking was predicted by an intelligent observer, Dr Tennant, who remarks, that "as it is for business, and not education, that young men are sent to India, it is difficult to foresee any benefit that will ever result from this measure. Instruction in the native dialects is, in general, all that is necessary to qualify them for the exercise of their duty; and this they have hitherto received from moonshees or interpreters, at the spare hours that are not employed in their different vocations." The Asiatic Society, instituted in 1784, by Sir William Jones, for the purpose of investigating the history, literature, and antiquities of the country, still continues to flourish.

The population of Calcutta was estimated some years ago, when a famine prevailed, and had reduced its numbers, at half a million; but, according to later statements, it is said to be nearly equal to 700,000. Calcutta is a place of immense trade. Ships of all nations frequent its port to carry off the rich productions of Bengal and the interior regions of India, in exchange for money or the superfluous commodities of the countries to which they belong.

Calcutta was selected in 1690 by Mr Charnock, the agent of the East India Company, as the most convenient spot for the establishment of a factory. The affairs of the settlement continued to prosper till after the middle of the 18th century. A new native sovereign, in hopes of rich plunder, resolved to expel the English from the country. He attacked Calcutta with an immense force; and the besieged, being few in number, and with scanty ammunition, were at last overpowered and made prisoners. But of 146 persons of both sexes, who were crammed into a dungeon called the *black hole*, including a space of only 18 feet square, and were kept a whole night in this miserable situation, twenty-three only survived the cruel calamity. Mr Holwell, the commander, was one of the survivors, and afterwards published a melancholy relation of the barbarous transaction, and erected an elegant obelisk near the spot to the memory of his fellow-sufferers, whose names it records. This dreadful event happened in the year 1756.

CALEDONIA, the ancient name of Scotland, or of part of that kingdom, for the industry and researches of antiquaries have not been able to fix its precise limits. According to some, ancient Caledonia included that part of Scotland which lies to the north of the Forth and the Clyde, while others extend it to the whole of Scotland. For an account of Caledonia, and of the struggle which the inhabitants maintained with the Romans, see *Tacitus* and Mr Chalmers' *Caledonia*.

CALEDONIA, NEW, a large island in the Southern Pacific ocean, which lies between south latitude $19\frac{1}{2}$ and $22\frac{1}{2}$, and $163\frac{1}{2}$ and $167°$ of east longitude; about 300 miles in length, but not exceeding 30 miles at its greatest breadth. A chain of mountains runs through its whole extent, rising in different ridges from 2000 to six or 7000 feet from the level of the sea. The coast is generally bold, and is defended by numerous rocks and sand-banks, and hence navigation is attended with considerable danger; and these difficulties in approaching the island, render the utmost vigilance and precaution necessary. The rocks, as far as Europeans have had an opportunity of examining them, are chiefly of the primitive class. Some ores of iron were observed, but no volcanic productions were seen.

The inhabitants of this island appear to be a robust, active people. Their houses, constructed of wood, reeds, and coarse grass for thatch, are of a circular form. Fishing is their chief employment; and this produce of their industry, with a few roots which they cultivate, forms their chief subsistence. The country is divided into different districts, each of which is governed by its own chief. This island was first seen by captain Cook in 1772, and has been since visited by the French navigators.

CALENDAR, or KALENDAR, a register of time, or of particular events. For the method of adjusting the artificial division of time, to make it correspond with the revolutions of the heavenly bodies, see ASTRONOMY.

CALENDAR, when employed as a law term, signifies a list of prisoners who are in custody of the respective sheriffs, and are to be brought to trial for their crimes at the assizes.

CALENDAR OF FLORA, is a register of the times in which plants of any particular district germinate, unfold their leaves, or shed their leaves and flowers, and ripen and disperse their seeds.

CALENDER, from the French *Calendre*, an engine for smoothing or putting a gloss upon cloth. In a more extended sense, a calender is a place where cloth is smoothed, lapped, and packed, previously to its being sent off to the market. The object of calendering is to give the cloth a more kindly feel, to make it appear of a finer texture, and, by condensing it moderately in a press, to pack in less bulk than in the uncalendered state. Some kinds of goods are not put through the calender; they are merely folded in the state they came from the bleachfield; and in such cases the goods are said to be soft dressed. Hard dressing signifies that they have been submitted to the operation of the machinery.

Besides the improvement in the appearance of the cloth resulting from the processes of calendering, the variety of forms into which it is folded, and the ornaments peculiar to each species, are of the highest importance in a commercial point of view; for, as the greatest part of our goods are merely imitations of the manufactures of other countries, it is still found necessary, when we send them in competition to foreign markets, that not only the original names be retained, but that their peculiar lengths, folds, and ornaments, should likewise be scrupulously observed; for a copious list of which, see the Table subjoined to this treatise.

The mechanical processes of calendering are of two kinds; one consists merely in smoothing the surface of the cloth, by passing it through between the rollers of the machine, previously heated with steam or iron heaters; the other, by means of friction, excited by the machinery, gives to the surface of stout fabrics a lustre, or very fine polish, which is known by the name of glazing.

The principal apparatus employed for these purposes is represented in Plate 38. Fig. 1. is a front elevation of a five cylinder or bowl calender, the end, or side of which, together with the wheel-work, is exhibited in Fig. 2. A, B, C, D, and E, Fig. 1. are the five bowls or cylinders, between which the cloth passes in the operation of calendering. The cylinders B and D are made of cast-iron, accurately turned and polished, and left hollow within, like a pipe, for the reception of the iron heaters or steam. The rollers A, C, and E, are made of paper, and are interposed, alternately, between the metallic rollers, on account of their elasticity, as the surfaces of two iron cylinders coming in contact would injure the cloth in passing between them.

These rollers are constructed in the following manner: A square axle of malleable iron is prepared, on which a number of circular pieces of pasteboard, with square holes cut in their centres, are placed, and which are rather larger in diameter than the intended size of the roller, to make allowance for turning and polishing. When a sufficient quantity of the pasteboard is thus applied to make the roller the requisite length, four iron rods are again run through it, parallel to the axis, on the ends of which is screwed a circular plate of iron, at each end of the roller, by means of nuts, as represented in the fig. In order to give the paper a sufficient degree of compression, so as to render it one solid mass, the roller is put into a stove, and exposed for several days to a strong heat, during which time the screws are frequently tightened, until the paper is as much compressed as possible. When the roller is removed from the stove, and left to cool, the pasteboard, by again endeavouring to expand, forms a most solid and elastic substance, which, when accurately turned in the lathe, and well polished, is found to be superior to any materials that have yet been discovered for this purpose.

The bowls or cylinders being thus prepared, the several dimensions of which, for a well going calender, are pretty accurately exhibited in Fig. 1; they are lodged in a strong cast-iron frame, similar to that represented in the plate. At each end of the frame is an apparatus *a*, *a*, connected to the cross-bar F, for occasionally raising or separating the rollers when the metallic ones become too hot, or when the machine is not working. This apparatus is raised and lowered by turning the screws *b* and *c*, the cross-bearers being placed at different distances from the ends of the metallic cylinders, by which the upper one is raised first, to make way for those below. They also raise the end of a wedge, which is introduced below each journal of the paper-roller C; but the pillows of the upper roller, A, are connected, directly, to the lower ends of the screws *b* and *c*, by means of which the rollers may all be separated from each other to equal distances, or their surfaces brought into contact at pleasure. In the end, *g*, of the cylinder B, an aperture is left, sufficiently large to receive the iron heaters, a small hole being only necessary in the other end for pushing them out, when required, by an iron rod. The cylinder D is adapted to steam, which is transmitted through the pipe *d*, and the condensed vapour is let off by the pipe *e*. Steam appears to have been first applied to the heating of calenders about the year 1805, by the late Mr John Millar, Ayton-place, Glasgow; and is found to be a very great improvement, not only as it saves time and fuel, but in meliorating the appearance of the goods. *Buchanan on Heating by Steam*, p. 208. Some calenders, however, are still heated with the iron heaters, some wholly with steam, and others are adapted to both.

The relative situation of the wheels for driving the calender will be seen in Fig. 2. The wheel 1. is the driver, which is put in motion by the power of horses, water-wheel, or steam-engine. It works into the teeth of the wheel 2, or the axle of the cylinder B. fig. 1. which is all the wheel-work requisite on the rollers of a common calender; for the other rollers revolve merely by friction, equal portions of their surfaces coming in contact in equal times. But as it is often necessary to change the motion of the calender while at work, an additional apparatus is employed for this purpose, which is represented in Fig. 3. A, is the lying shaft, which is kept in motion by the engine or other power; B, part of the shaft *b*, Fig. 1. which turns the driver 1. The two level wheels, *a* and *e*, having circular bushes, are loose upon the lying shaft A. The clutch *i*, is carried round with the shaft by means of a feather, which slides in a groove cut in it below the clutch-box. Hence, when the clutch *i* is thrown into the arms of the wheel *a* by the lever *o*, the calender is put in motion in one direction; but when it is thrown into the arms of the other wheel *e*, the motion is reversed. The calender is stationary when the clutch is disengaged from both wheels.

Calenders are now generally so constructed, that they may, with very little trouble, be occasionally converted into glazing engines. This is effected by fixing a wheel on the axle of the metallic cylinder D, of a greater diameter than that on the cylinder B, and conveying the motion from the latter to the former, by means of an intermediate wheel 3. The velocity of the two metallic cylinders, therefore, will be in the reciprocal ratio of the diameter of the wheels on their respective axles. Hence, the slow motion of the cylinder D, added to the inertia of the paper roller C, generates a friction or *rub*, between the latter and the cylinder B, which glazes the surface of the cloth submitted to their action.

For this invention we are indebted to the late Mr John Millar, already mentioned, who farther extended the principle to the construction of an engine capable of glazing two pieces of cloth at the same time, while, in every other respect, it answers all the purposes of a calender. Fig. 4. is a section of this engine, exhibiting the diameters of the bowls or cylinders, and the number of teeth in the different wheels. In this machine are three metallic cylinders, between which are interposed two paper ones, which are distinguished by being lighter shaded than the others, the wheels being represented by dotted circles. When this engine is employed as a common calender, the centre wheel only, of 33 teeth, is acted upon by the power, the two intermediate wheels of 28 teeth being removed, and the other bowls revolving by friction, as in the one already described. As the diameter of the cylinder B, however, is only $10\frac{1}{2}$ inches, and that of G 15; and since their circumferences are as their diameters, it will be $\frac{15}{10.5} = 1.43$, for the times that B should revolve while G revolves once, that their surfaces may move through equal spaces in equal times. But when the intermediate wheel of 28 teeth is applied, the motion is communicated from the wheel of 33 teeth to the large one of 65, on the axle of the cylinder G; and, therefore, $\frac{65}{33} = 1.97$, is the ratio of the times in which they now revolve; which multiplied into the circumference of the cylinder B, viz. 33, gives 64.984, or 65, for the space, or number of inches, which the circumference of B moves through, while that of G moves only through 47.124. The difference of these velocities, therefore, produces the friction or *rub*, which converts this part of the calender into a glazing engine. The under part of the calender is exactly the same as that now described; which gives it double the efficacy, as a glazing engine, of those in general use. The portions of this engine, together with the drawings, Figs. 1 and 2, with the exception that one of these cylinders is adapted to iron heaters, were taken from two calenders constructed by Mr Millar, now the property of his successors Messrs Hunter and M'Ilwham, and which do not appear to have been yet surpassed, in the neat and expeditious manner of executing their work, by any modifications that have since been made of his principle.

Besides the five-bowl calender we have described, there is another in pretty general use, containing three bowls only, and which has likewise been converted into a glazing engine, by the application of additional wheel work. In the three-bowl calender, a section of one will be found in Fig. 5, the centre cylinder only is of metal, the other two being made of paper. On the centre cylinder is a wheel of 69 teeth, which, together with the driver, is all that is necessary for the common process of calendering. But, in order to adapt it to glazing, there is a rack of 52 teeth fixed round the end of the lower bowl, into which an intermediate wheel of 22 teeth works; and this wheel, again, is driven by a pinion on the axis of another wheel of 43 teeth, which is driven by the large wheel of 69, on the axle of the metallic cylinder. This train of wheel-work, which is represented by the circles in Fig. 5, diminishes the velocity of the lower bowl, and produces the rub on the surface of the centre cylinder.

It may be necessary here to observe, that in the simple process of calendering, the end of the piece of cloth is entered, in the five-bowl calender, Fig. 1. between the rollers A and B, returned between B and C, entered again between C and D, and returned finally between D and E. In the three-bowl calender, however, it only passes through above the centre cylinder and returns below it. In the process of glazing, the cloth passes between those rollers only which produce the rub.

The invention of the rub calender, though one of the greatest improvements that have been made in the business, has not been able entirely to supersede the use of flint in the process of glazing; and the reason assigned is, that the beautiful gloss or polish, given to the cloth by the smooth surfaces of the warm cylinder, is liable to lose its lustre by the smallest damp or exposure to the air, while that given by the strong attrition of the flint is permanent under similar circumstances. Engines for this purpose, therefore, still form a part of the apparatus of almost every calender. Where these engines are employed, a number of them are usually connected together, and the whole driven by a crank, or any other means of applying power that may suit the situation in which they are placed. An elevation of two of these engines, which exhibit their connection, will be found in Fig. 6. *a*, *b*, is a table on which the cloth is spread while under the operation of the flint. This table, which is only about five or six inches broad, is composed of pasteboard, strongly compressed by screws between two iron plates, forming an elastic substance, similar to that of the paper bowls. The flint, *e*, is fixed by a screw into the lower end of the bar of iron B, which is connected to the wooden spring C, by a joint on which it oscillates. The flints are driven from *a* to *b*, alternately, by two parallel bars of iron A, between which they work, and to which they are attached, or from which they may be disengaged at pleasure by the catch *i*. These bars receive their motion from the shaft *m*, which is driven by a crank, or otherwise connected to the power.

When the cloth is to be submitted to the operation of glazing, the flint is brought into contact with the table, by pressing down the lever *x* with the foot, and placing it below the catch *y*; and the rub is adjusted by a screw on the rod which connects this lever to the spring C. The cloth being previously rubbed over on one side with wax, is wound on a small roller in an iron frame, at one end of the table, and is received on another at the opposite end; and the person who attends the machine, moves the frame across the table, and exposes a new portion of the waxed surface of the cloth, at each double stroke, to the action of the flint. A machine has also been invented for waxing the cloth in passing through the glazing engine; but this has now fallen into disuse, and the wax is rubbed over the surface of the cloth simply by the hand.

Having explained the mechanical processes of calendering, and the machinery by which they are conducted, what remains of the business consists chiefly in folding, pressing, ornamenting, and packing the goods, in a manner suitable to their different qualities, or to the several markets to which they are destined. Muslins were formerly put through a small calender made on purpose for these fabrics, but they are now folded in the state they come from the bleachfield. Besides these goods, Madras pullicats, Bandanas, York stripes, jeans, and jeannets, dimities, prince's cord, &c. are also dressed soft; ginghams and printed calicoes are sometimes dressed soft and sometimes glazed. Checks, made up as listadoes, brown linens, white cotton platillas, rolled checks, and some others, are prepared by damping, and letting them lie in that state about six hours. When dry, and put through the common calender, the outer yard or fold is rubbed over with paste made of flour or size, and again left to dry. After this the pasted fold is put three or four times through the rub-calender, backward and forward, which gives a highly finished gloss to that part of the piece which is exposed to view when folded.

After the goods have been made up into their respective folds, they are set into the press, with a smooth board between every one, two, or three pieces, according to their qualities; and frequently a sheet of glazed pasteboard is laid next the outer fold of each piece, to give it a more glossy appearance. They are allowed to remain in the press for a few hours, less or more, as the time will permit. The common screw press, similar to that represented in the plate, on Bandana manufacture, was universally employed in calenders until the invention of the hydrostatic press by Mr Bramah. But since the great power and

CALENDER.

facility of working this engine have become generally known, it has almost entirely superseded the other, not only in our calenders, but in all other public works where a great pressure is required.

When the goods have been folded and ornamented, as directed in the following table, they are then ready for packing. For the London and American markets they are packed in small lots of about a dozen pieces each, but for the West Indies they are merely packed in boxes or trunks previously well lined with paper.

TABLE of the Lengths of the different kinds of Goods *as they are prepared for the Market, the manner in which they are Folded, and the Marks or Ornaments attached to them.*

Names.	Length.	How Folded.	Ornaments, &c.
Muslins . .	10, 12, or 20	$18\frac{1}{2}$ by 13	No ornament, only a ticket with the length.
Bandanas . .	13, 14, or 15 hd	$11\frac{1}{2}$ by $11\frac{1}{2}$	No ornament but a ticket.
York stripes .	14 or 30	Roll'd & paper'd	Tied with slips of paper.
Jeans & jeannets	30 yards	Ditto ditto	No ornament.
Dimities . .	30	Ditto ditto	Ditto.
Prince's cord	30	Rolled	Doubled, and ornamented with a gold stamp.
Granderills .	14 or 30 yards	Ditto	No ornament.
Bontons . .	12 or 14		$\frac{3}{4}$ checks doubled, and tied in a round fold, with 2 slips red paper, about 2 inches broad.
Listadoes . .	28, 30, or 35	6 by full breadth	$\frac{7}{8}$ checks, cotton or linen, tied with 4 pink slips, 1 with a silver stamp, about $3\frac{1}{2}$ inches broad.
$\frac{3}{4}$ Cotton, or cotton & lin. checks	12, 14, or 20	Tied round	Doubled, and tied with 2 slips, about 2 inches broad.
$\frac{6}{4}$ Ditto . .	20	$16\frac{1}{2}$ by 13	No ornament, only a ticket, with the length.
Kentings . .	6 to 7	9 by $6\frac{1}{2}$	Linens or cottons, with a tuft of silk on each selvage.
Estapillas .	6 to 8	9 by 8	Linens or cottons, with 4 silk tufts on each selvage, and papered with black paper.
Rouens .	45	9 by full breadth	Coarse linens, with stamp of flower de luce.
Crown dowlas	51	Tied round	Coarse linens, with crown stamp.
Anchor dowlas	51	Tied round	Coarse linens, with anchor stamp.
Cassarillas .	20 or 20	Roll'd f. breadth	Coarse linens, with a star.
Platillas .	28, 30, or 35	6 by full breadth	Linens or cottons, with 4 slips, $3\frac{1}{2}$ inches broad, with a silver stamp on one of the slips.
Platillas royales	28, 30, 35	Ditto	A finer kind of ditto, with 4 slips of purple, royal, or black paper,, and a silver stamp.
Britannias .	6 $6\frac{1}{2}$, or 7	15 by 15	Linens or cottons, with 2 tufts, silk or cotton, 1 on each selvage, & a star opposite each tuft.
Russia shirting	36	18 by half breadth	Rolled on a board 15 inches broad, with the Russian arms on the outside.
Russia duck .	36	12 by full ditto	Rolled on a board about 10 inches broad, with the Russian arms on the outside.
Colerains . .	28 to 30	9 by full breadth	Coarse linen, no ornament.
Linen shirting .	25	Rolled double	Generally a gold ornament on the centre.
Pullicates . .	8 handfs.	17 by 17	No ornament, but a ticket.
Ditto .		$11\frac{1}{2}$ by $11\frac{1}{2}$	Ditto ditto.
Madapalams . .	28 yards	12 by full breadth	Stamped on outside with Madapalams, in large letters.
Ginghams, .	36	18 by 12	No ornament but a ticket.
Pullicatures .	12	12 by 9	Ditto ditto, tied with 2 slips.
Caledonias .	12	12 by 9	Ditto ditto.
Creas	20 to 36	45 by 15	Coarse linens, stamped with a dolphin, black, red, blue.

CALIBER, or Calibre, denotes the diameter of any body; and caliber compasses are formed with arched legs for measuring that diameter. They are chiefly in use for ascertaining the diameters of the several parts of a piece of ordnance or of bullets, &c. The caliber rule is an instrument in which a right line is so divided, that the first part being equal to the diameter of an iron or leaden ball of a pound weight, the other parts are to the first as the diameters of balls of two, three, or four pounds are to the diameter of a ball of one pound. This instrument is in use among military engineers for determining, from the weight of the ball given, its diameter, or from its diameter to ascertain its weight.

CALICUT, a district in the province of Malabar, which extends along the sea coast, between the 10° and 12° of north latitude, is inhabited by the Nairs, a remarkable Hindoo sect, and was ceded to the East India company in 1792.

CALICUT, the capital of the district of the same name on the coast of Malabar. The Portuguese, under their celebrated navigator, Vasco de Gama, arrived at this place in 1498, after a voyage of ten months from Lisbon. The town was destroyed in 1789 by Tippoo Sultan, and the inhabitants were removed to Furruckabad; but in little more than a year the province was conquered by the English, and the inhabitants were restored to their old habitations. In 1800, the town had increased to 5,000 houses, and its improvement was rapidly going on. Ginger, turmeric, pepper, teak, and sandal wood, cardamoms and wax, are the chief exports. The distance from Seringapatam is 129 miles.

CALIFORNIA, an extensive region of North America, which lies between the 22 and 40 degrees of north latitude; has for its boundary on the west the Pacific ocean, and is separated from the continent on the east by the gulf of California, the river Colorado, and a mountainous ridge; and includes a superficial area of more than 9000 square leagues. It is divided into New and Old California; the northern division having the denomination of New, and the southern being called Old California. This part of America was discovered by the Spaniards in 1534. The northern part of it, or New California, was visited by Sir Francis Drake in 1577, and it received the name of New Albion from the English circumnavigator.

The southern division of this peninsula is rugged and sterile; a chain of mountains, some of which rise 5000 feet above the level of the sea, and are either destitute of verdure, or covered with low shrubs, traverses the interior. In some of the vallies and the plains near the coast, the soil is fertile, and is well adapted either for tillage or pasture. A great scarcity of water prevails in this part of the country. In an extent of 200 leagues two rivers only flow into the gulf of California, and many of the springs that issue from the ground are soon lost in the dry sand. But the northern division, or New California, is well watered, clothed with woods, and enjoys a fertile soil. Grain of various kinds, and the roots and fruit trees of Spain, beside the fruits of tropical regions, are successfully cultivated in the gardens and fields.

Hares and rabbits are common; a large kind of deer is frequent in the forests; and otters, whose skins have of late years furnished a valuable commercial commodity, are very abundant. Partridges, and a great variety of other land birds, breed in the woods, and numerous sea-fowl are found on the shores. Horses, cattle, sheep, and other domestic animals, have greatly increased. The sea coasts furnish great quantities of fish; and in the southern part of the peninsula, the pearl oyster has been a source of considerable wealth to the Spanish colonists.

The Indian population of this peninsula seems to be on the decrease; but a striking fact is recorded by Humboldt, that the inhabitants of New California, including the Indians attached to the soil, and who had begun to improve it by industry and culture, were more than doubled in twelve years. Fishing, hunting, and agriculture, are the chief occupations of the natives of this country. The original inhabitants, when first discovered by the Spaniards, were in a very savage state. Entirely destitute of clothing, they were attached to many barbarous practices, and were often engaged in war with hostile tribes. Since the establishment of missionaries in 1770 for their conversion, civilization and habits of industry have made considerable progress where the power and influence of the Spaniards reach.

CALIPH, or KHALIF, signifying successor, or vicar, is the appellation of the successors of Mahomet. These caliphs possessing not only sovereign authority, but also the most unbounded influence in their priestly character, were the most absolute monarchs. It was the duty of the caliph, in his function of high priest, to begin the public prayers every Friday in the chief mosque, to conduct the pilgrims to Mecca, in person, to march at the head of the armies, and to grant investiture to princes.

CALIPPIC PERIOD, a series of 76 years which perpetually recurs, and which elapses the middle of the new and full moons, and returns to the same day of the solar year, according to the calculations of Calippus, an Athenian, from whom the name is derived.

CALL is a term among fowlers, denoting the peculiar voice or cry of a bird to its young, or those of its own kind, the knowledge of which is of great importance to those who are employed in bird-catching; for this call being imitated by a bird trained for the purpose, or by an instrument, allures the wild bird to the fowler's net.

CALLA, Ethiopian Wake-robin, a genus of plants belonging to the class Monœcia, and of which Calla Ethiopica, a native of the East Indies, is a common ornament of the green house and parlour.

CALLAO, a sea-port town of Peru, in South America, is one of the most spacious and most secure harbours on the western coast of America. It may be considered as the port of Lima, which is about eight miles distant up a river of the same name. Callao has twice suffered severely from earthquakes, first in 1687, and afterwards in 1746, when, of 4000 inhabitants, not more than 200 escaped that dreadful calamity.

CALLIMACHUS, a Greek poet, who was a native of Cyrene in Lybia, and flourished at Alexandria in Egypt, in the reign of Ptolemy Philadelphus, 280 years before the Christian era. His compositions, consisting of hymns, elegies, and epigrams, are greatly admired for their beauty and classical elegance; and he has been pronounced by Quinctilian, the first elegiac poet of Greece. Beside numerous editions of his works, with notes and annotations by learned critics, an English translation in verse has appeared.

CALMAR, a sea-port town of Sweden, and situated upon the Baltic, opposite to the island of Oeland, from which it is separated by a strait seven miles broad. The population is between 2 and 3000, and the trade in timber, hemp, and alum, is considerable. Some of the inhabitants are occupied in the manufacture of woollen stuffs.

CALMUCKS, are tribes of independent Tartars, who have preserved the Mogul language, manners, dress, and religion, as well as their pastoral and wandering mode of life. At one period they occupied a great extent of the interior of Asia; but the extension of the Russian territories on the one hand, and of the Chinese on the other, has driven them from their original settlements to seek an asylum in distant regions. Many of the tribes have since acknowledged the authority of both these powers, and are engaged by them for military service. The wealth of the Calmucks consists entirely in their flocks and herds, and when the pastures are exhausted in one place they remove to another. They are distinguished by their hospitality, and are strongly attached to their chiefs. The exchange of their horses and cattle for corn, different kinds of cloth, various utensils, and warlike instruments, is their only trade.

CALNE, a town of Wiltshire in England, stands on the banks of the river Marlin, is well built, and, from the remains of edifices and coins that are occasionally found, seems to have been a place occupied by the Romans. The church is a large structure, beside which there are meeting-houses for presbyterians and dissenters. The population in 1811 exceeded 5000; and the inhabitants are employed in the manufacture of woollen stuffs of different fabrics, the machinery for which is driven by the water of the river.

CALTHA, a genus of plants belonging to the Polyandria class, of which one species, *Caltha palustras*, or marsh marygold, only is known, and is a native of this country, forming a fine ornament of the wet grounds where it grows. The flower-buds, it is said, preserved with salt and vinegar, are a good substitute for capers, and the juice of the petals, boiled with alum, gives a yellow colour to paper.

CALVADOS, a department of France, which is formed of part of Normandy, and is bounded on the north by the sea, and on the west by the department of La Manche, on the south by the department of Orne, and on the east by the department of Eure. It includes about 375 square leagues, with a population of 506,000. Grain, hemp, flax, wool, honey, wax, and cyder, are enumerated among the productions of this district. The contiguous sea furnishes plenty of fish of all kinds, and the rocks abound with shell-fish.

CALVIN, JOHN, the celebrated reformer, was born at Noyon in Picardy, in 1509. The early part of his education, conducted privately, being completed, he studied at the college of La Marche in Paris, under Cordery, a teacher of great celebrity; and, having finished a course of philosophy, he was appointed, by the bishop of Noyon, first to a chapel, and to two curacies successively, and in these situations he preached and performed the sacred functions of his ministry. Some change in his views with regard to the doctrines and practices of the church of Rome, supported by the advice and recommendation of his father, led him to form the resolution of directing his studies to another profession. With this intention he commenced the study of law at Orleans; but while he was proceeding in acquiring a knowledge of his new profession, the study of divinity was not neglected. In the farther prosecution of his professional studies, he resided some time at Bourges, where he had also an opportunity of extending and improving his knowledge of the Greek language, under an excellent Greek scholar.

In his 23d year he revisited Paris, and published a Commentary on Seneca's book *De Clementia*, which perhaps merits little notice, excepting from the change of his name from Cauvin to Calvin, which, from causes not well understood or easily explained, seems to have excited great attention, and to have exposed him to much obloquy. By some, indeed, it was regarded as an early proof of his pride, and by his friends it was thought necessary to come forward in his defence.

The freedom of Calvin's opinions, with regard to the new doctrines, began to be publicly known; and, to avoid the persecution which awaited him, he retired from Paris for a short time; but his papers and books were seized, and it appeared from his correspondence, that his own views, as well as those of his friends, were directly hostile to the church of Rome. On his return to Paris in the succeeding year, a conference was appointed between him and Servetus, a Spanish physician settled in France, in whose tragical end, 20 years afterwards, Calvin was deeply implicated; but the physician not choosing to enter the lists with his opponent, failed to appear. Retiring to Basle in Switzerland, Calvin studied the Hebrew language, and first published his *Institutions of the Christian Religion*, various editions of which, in different forms, afterwards appeared. Having made a short visit to Italy, where the reformation had also commenced, he returned to France; but finding his personal safety in danger on account of the opposition which was made to all those who professed the reformed religion, he was proceeding to Basle or Strasburg, by the way of Geneva, where finding the number of protestants rapidly increasing, he was invited to accept of the office of minister of their church, and professor of divinity. In the discharge of his sacred functions he was involved in much controversy, arising partly from the influence of former opinions on those over whom he presided, and partly from his own dogmatical spirit, which refused to yield or accommodate itself to the peculiar views of others. These differences at last broke out into an open rupture, which terminated in the expulsion of Calvin from his official situation. He retired to Strasburg, was appointed pastor of a French church and professor of divinity, and was nominated to attend the diet at Worms, which met in 1541, for settling religious differences.

Solicited by the republic of Geneva, who now began to regret the loss of their pastor, he returned in 1540, and resumed his sacred functions; and during the last 24 years of his life, he was not only assiduously employed in performing the pastoral duties of his office, but in framing political regulations for the government of the republic, and in numerous controversies with those who opposed the Protestant doctrines. His reputation extended far beyond the limits of Switzerland, and attracted students from different parts of Europe to attend his lectures.

But how much is it to be regretted that this great man should have cherished that violent and cruel spirit of intolerance, against which he had such just reason to complain in the church from which he had separated. This intolerance could not escape observation in his intercourse with the people of Geneva; but it exceeded all bounds when he encouraged persecution for conscience sake, and seems to have been the prime mover in the apprehension and condemnation of Servetus, who was brought to the stake on the very day of his trial for his religious opinions; and yet his apologists in the present day, coolly speak of his error being the error of his age, and the reprobation of his conduct as outrageous clamour. It is alleged too, and strongly argued, that the punishment of heretics was positively required by the constitution of Geneva, and that the condemnation and punishment of that unfortunate man were approved by eminent divines. Nothing can be more fallacious than such reasoning; and it is greatly to be feared that those who employ it would not be scrupulous in pursuing the practice which it seems to recommend.

The close of the life of Calvin was marked by severe bodily affliction. He died in May 1564. His irritable and dogmatical temper undoubtedly exposed him to much of that controversy and trouble, which a milder and more conciliating spirit would have escaped; but he was a man of great learning, and the labours which he performed, and the works which he published, afford ample proofs of his indefatigable industry. Beside the works already noticed, one of his most voluminous productions is his Commentary on the Scriptures.

CALUMET, a symbolical instrument in use among the North American Indians, and considered as the emblem of peace. This instrument is about four feet in length, the bowl or head is made of a reddish stone, and the tube is a reed or a piece of light wood hollowed out. It is usually adorned with various figures, and sometimes with hieroglyphical representations; while the ornaments, whatever they be, whether descriptive or fanciful, are said to be peculiar to each tribe. The calumet is presented when warriors of different nations meet; it forms a large share of the ceremonies observed on the arrival and reception of ambassadors; even during the rage of battle, if it be offered and accepted, hostilities cease; and, in the celebrated Indian dance which takes its name from this instrument, one of the two performers engaged in it, is furnished with the pipe of peace. This last entertainment is reserved for great occasions, such as the arrival of strangers or the reception of ambassadors. A resemblance has been traced in the ornaments of the calumet to the caduceus or rod of Mercury among the ancients, which was destined to similar purposes; and hence the remarkable similarity of customs in some things among nations very remote from each other in time and place, has been noticed as a striking circumstance.

CALYCANTHUS, a genus of plants belonging to the Icosandria class, and of which the species *floridus*, or Carolina Allspice is remarkable for its aromatic flavour.

CAMARAN, or KAMARAN, an island of the Red sea, about two miles from the Arabian coast, is about 16 miles in length, and affords good anchorage for large ships, in a bay on the eastern part of the island, from which fresh provisions and good water may be procured. The soil is extremely fertile, and produces sugar, millet, and dates; cattle are reared on the pastures; and the coast furnishes white coral, pearl oysters, and fish, with all which the inhabitants carry on trade with the contiguous continent.

CAMBAY, a city of the province of Guzerat in Hindostan, not far from the gulf of the same name, and on the banks of the river Canari, was formerly one of the most flourishing and most opulent cities of the east, and the sea at one time washed the walls; but vessels of any magnitude can scarcely approach nearer than four leagues. The surrounding territory, from its rich soil, furnished some valuable commodities for trade, as cotton, opium, indigo, and sugar; and the port of Cambay was frequented by ships not only from the different regions of the East Indies, but from the Persian and Arabian gulfs.

CAMBOGE, CAMBOYA, or CAMBODIA, a region of Tonquin in Asia, lying between the 9th and 12th degree of north latitude, and having Cochin-China for its boundary on the east, and the kingdom of Siam on the west. Several mountainous ridges form a kind of natural limits to this country; the river Camboge, or the Japanese river, one of the largest in the territory, derives its origin from these mountains. Corn, rice, sugar, indigo, gums, fine woods, hides, elephant's teeth, are enumerated among the commercial commodities of the country. The inhabitants, who are estimated at one million, are composed of Chinese, Japanese, and Malays. The capital, called also Camboge, stands on the banks of the river of the same name, which is navigable even for vessels of large size to the town.

CAMBRAY, a city of the Netherlands, stands on the banks of the Scheldt, is well built, has some spacious streets, and the episcopal palace, the cathedral, and some other public buildings, are magnificent edifices. It is strongly fortified and defended by a citadel.

The population of Cambray is about 16,000, and it once possessed flourishing manufactures, and enjoyed great commercial prosperity. The manufacture of linen, cambric, lace, tapestry, hosiery, with that of salt and black soap, and extensive bleaching concerns, still occupy the industry of the inhabitants.

CAMBRIA, the ancient name of the principality of Wales.

CAMBRIC, a kind of linen cloth, of a very fine and close fabric. See CLOTH MANUFACTURE.

CAMBRIDGE, the capital of a county, and seat of a university of the same name, in England; derives its name from the river Cam, on the banks of which it is situated, and from the bridge which forms the communication between the two parts of the city; and is supposed to be the *Granta* of the Romans. Numerous utensils and coins, as well as fragments of urns which belong to that people, clearly shew that it was once a Roman station. But the origin of Cambridge is ascribed by some to a much higher period of antiquity. In the present day, it is about a mile long, and about half a mile broad; but the ancient town is supposed to have been considerably greater both in extent and population. The finest street, which

Cambridge.

extends the whole length of the town, is Bridge-street, but the streets in general are not remarkable for their uniformity or the houses for their elegance.

The population of Cambridge which, in 1801, amounted to 10,087 inhabitants, had increased in 1811 to 11,108. Few or scarcely any manufactures have been established. The shops are numerous for the supply of the different colleges; the trade in coals, iron, and corn, by means of the inland navigation, is considerable; a great deal of butter from Norfolk and the isle of Ely is transmitted from Cambridge to the London market; and the trade in wool, hops, leather, and cheese, at two annual fairs in midsummer and September, is extensive, although of late years it has suffered a very great decline. Among the beneficent institutions are, the General Infirmary for the relief of the sick poor, several charity schools, and a number of alms-houses. Some of the churches of Cambridge are remarkable structures; of which the church of St Sepulchre, or the Round church, from its circular form, presents a singular specimen of ancient architecture. It is built in the Saxon style, after the model of the Holy Sepulchre at Jerusalem. Great St Mary's, or the University church, is in the Gothic style, and is furnished with a lofty tower, surmounted by four splendid pinnacles. The members of the university attend divine service in this church, from which the name is derived.

University.—The university, and the buildings connected with its different colleges, constitute the great ornament of Cambridge. A very early period is assigned for the first establishment of schools or places of instruction at Cambridge. Colleges were built and endowed in the time of Edward I. The university now consists of twelve colleges and four halls, which possess very extensive privileges. Every college is a corporate body, regulated by its own statutes, but subject to the controul of the common laws of the university. The chief officers are, the chancellor, who is generally a nobleman, the high-steward, the vice-chancellor, two proctors, beside other officers, for regulating and superintending both the literary and economical affairs of the establishment. The government of the whole university is vested in the senate and these officers; and the senate is composed of all doctors and masters of arts.

St Peter's college, the oldest in the university, was founded in 1257. The chapel belonging to this college is an elegant edifice; and the window over the altarpiece, on which the crucifixion is represented in painted glass, is greatly admired for its beauty.

Clarehall, originally founded in 1326, was entirely rebuilt in 1638, stands on the east bank of the Cam, and is one of the most magnificent structures in the university. The chapel is peculiarly elegant in the style of its decorations, and a splendid alcove over the altar is adorned with a fine painting of the Salutation, by Cipriani.

Pembroke-hall, founded in 1348 by the countess of Pembroke, who, in consequence of her husband being killed at a tilting-match on her wedding-day, determined to retire from the world, and devote her extensive possessions to the establishment and support of beneficent institutions.

Corpus Christi, or *Bene't College*—the latter name being derived from St Benedict, in consequence of its vicinity to the church dedicated to that saint, was finally endowed in 1356. The library of this college possesses a valuable collection of manuscripts, chiefly connected with ecclesiastical affairs, which was presented to it by archbishop Parker, with the peculiar restriction, that if 25 books are at any time missing, and cannot be recovered in six months, the whole devolves on Caius college and Trinity-hall successively, and on the same terms.

Gonvile and Caius college, usually called Key's college, originally founded in 1348, by Edmund Gonvile, was greatly enlarged, and, with a new charter of incorporation, was more richly endowed in 1557, by Dr John Caius, physician to queen Mary.

Trinity-hall was originally endowed about the middle of the 14th century, by William Bateman, bishop of Norwich, and received a splendid benefaction of L.20,000, which was left in 1747 by Dr John Andrews, for the enlargement of the buildings.

King's college derives its name from its royal founder, Henry VI. who, in 1441, established a small seminary, but in a short time enlarged the plan, and contributed more liberally to its endowment. The chapel of this college is greatly admired for the sublimity, elegance, and ingenuity displayed in its design and construction, and is regarded as one of the finest specimens of gothic architecture, while its internal decorations and the exquisite beauty of its painted windows, the subjects of which are taken from scriptural history, correspond with its external magnificence.

Queen's college, founded in 1448, by Margaret of Anjou, consort of Henry VI., was enlarged by the queen of Edward IV.

Catherine-hall was founded in 1475, by Robert Woodlark, chancellor of the university.

Jesus college occupies the site of an ancient benedictine nunnery, which was suppressed by Henry VII. and its possessions granted to John Alcock, bishop of Ely, who in 1497 endowed this college.

Christ's college, originally founded in 1442, was removed from its former situation, and was finally endowed in 1506.

St John's college was originally endowed about the same time as Christ's church; but was not finally completed till 1516.

Magdalene college, which was originally a priory for canons regular, was endowed in 1542, by Lord Audley, chancellor of England. The altar-piece of the chapel of this college is a singular production in stucco.

Trinity college, founded and endowed in 1546 by Henry VIII., is one of the richest institutions in Cambridge. The buildings are remarkable for their magnificence, and the chapel, a gothic structure, erected by Mary and Elizabeth, the daughters and successors of the founder, contains a fine statue of Sir Isaac Newton, executed by Roubilliac. The library of this college is also a magnificent building, which is greatly admired.

Emanuel college was founded in 1584, by Sir Walter Mildmay; and Sidney Sussex college, which was originally a monastery of Grey Friars, was founded by the executors of the countess of Sussex. It has an elegant hall, and its chapel has been lately rebuilt.

Downing college, the most recent establishment in Cambridge, was founded by Sir George Downing; but the will of the founder being disputed, the legal discussions which followed were not finally closed till the year 1800, when the great seal was affixed to the charter of incorporation. This institution consists of a master, a professor of English law, a professor of medicine, and 16 fellows.

The number of fellows belonging to all the colleges exceeds 400, and the number of members exceeds 2000; but it rarely happens that more than 1000 are resident in the university during term. The number of scholarships is nearly 500; besides which, more than 200 inferior officers and servants are maintained on the foundation. The senate-house, in which the public business of the university is transacted, is a splendid edifice, which was erected in 1722. The schools and library compose an extensive pile of building. The botanical garden on the south east quarter of the city covers 5 acres, includes a magnificent green-house of 100 feet in length, besides apartments for lectures on botany, chemistry, and mineralogy, and is furnished with a rich and extensive collection of plants of all kinds.

CAMBRIDGESHIRE, an inland county of England, is bounded on the north and west by Lincoln, Northampton, and Huntingdonshires; and on the south and east by the counties of Bedford, Hertford, and Suffolk; is about 50 miles in length and about 25 miles in breadth, including a superficial area of about 437,000 acres, one-third of which is under tillage, one-third in pasturage, and the other third is still in an uncultivated state. That tract of country which is called the isle of Ely, and consists of fenny ground, intercepted by numerous drains and channels to carry off the water, composes the northern part of the county, and those parts of it which have been drained have been converted into rich meadows or excellent corn land. In some parts of the county the land is pretty high, but produces abundant corn crops, and never rises to a mountainous elevation. The dairy husbandry is successfully practised in some of the districts, and the butter and cheese esteemed for their excellence and rich flavour. Great numbers of sheep are reared on the upland pastures and extensive downs. A good deal of saffron is raised in those parts of the county which border upon Essex. The chief rivers of Cambridgeshire are the Cam and the Ouse. The chief source of the first is in Hertfordshire, and having received various tributary streams, and having passed through Cambridge, falls into the Ouse; the last rises in Northamptonshire, flows through the counties of Buckingham and Bedford, and, having traversed Cambridgeshire and part of Norfolk, discharges its waters into the ocean at Lynn-regis. But beside these natural currents, numerous artificial streams carry off the redundant water from the fenny grounds.

The population of Cambridgeshire was estimated in 1801 at 89,346, and in 1811 had increased to 100,109. Few manufactures have been established in this county. In the neighbourhood of Ely, white bricks, which have been long famous, and a coarse kind of pottery, are made of the clay found on the spot, and give employment to many of the inhabitants. The spinning of yarn for the manufactures of Norwich occupies the industry of another portion; but the pursuits of the great body of the population are chiefly directed to agriculture.

CAMDEN, William, a learned Englishman, was born in London in 1551; was educated at Christ's hospital and St Paul's school, and afterwards studied at Oxford; but being disappointed of a fellowship, he returned to London, and successfully prosecuted his studies. Having afterwards obtained the degree of bachelor of arts at Oxford, he was afterwards appointed second master of Westminster school, and in 1593 was promoted to the head of that seminary. While he was engaged in the laborious duties of the institution, he collected and arranged the materials for his great work, entitled *Britannia, or a Description of Great Britain*. This arduous work, originally composed in Latin, has been several times translated, with large additions; but the best editions are those of Bishop Gibson and Mr Gough. Mr Camden was also the author of a Greek grammar, which appeared in 1597, and was long taught in all the public schools of the kingdom; of an account of the monuments in Westminster abbey; a narrative of the gunpowder plot; and annals of queen Elizabeth. He was also the author of various essays on the antiquities of Britain, and he founded a professorship of history at Oxford. He died in 1624, when he had reached the 73d year of his age. It had been his custom to spend the anniversary of his birth in religious exercises and deeds of charity. In his will he had requested to be buried privately; but he was interred with great funeral pomp in Westminster abbey, opposite to the tomb of the poet Chaucer, and a marble monument was erected to his memory.

CAMEL, a genus of quadrupeds belonging to the order of Pecora. See Mammalia.

Camel, a machine which is employed in Holland for raising ships over the sand banks in the Zuyder sea. This machine, invented, it is said, by the celebrated De Wit, is composed of two parts, the outsides of which are perpendicular, and the insides of a conical form to fit the sides of the ship. Each part is furnished with plugs for admitting the water, and with pumps for discharging it. Being towed out to the vessel which is to be lifted over the bar, they are sunk on each side, and secured with cables; the plugs being introduced during the ebb, for excluding the water when the tide flows, the force of the rising tide buoys up the machine, with the vessel attached to it. Similar machines are employed at Petersburgh to lift vessels over the bar.

CAMELLIA, or Japan Rose, a genus of plants belonging to the Monadelphia class, of which some species and varieties are fine ornaments of the green-house.

CAMELO-PARDALIS, the Camelopard, a species of quadrupeds belonging to the genus Cervus, which is a native of Africa, and remarkable for its great stature. See Mammalia.

CAMEO, is a variety of Calcedony, composed of distinct layers of different colours, and on which sculptures are executed either in high or low relief. The ancients seem to have excelled in works of this kind, and some of their productions are highly prized as the most precious relics. But it is not true, as has been asserted, that the moderns have in vain attempted to imitate these minute sculptures. The reason of the failure is, that they do not receive an adequate reward for their labour. That variety of calcedony called onyx, which is composed of layers of different colours, is employed for this purpose; and if two layers be employed, the one a pure white and the other bluish, the whole of the white layer is removed, and the raised parts of the figure, as, for instance, that of a head, only are retained, and thus the figure, which is pure white, has the appearance of being placed on a blue ground; or the layers being reversed, and the figure being cut in low relief, it will appear a white figure sunk in a blue ground.

CAMERA LUCIDA, an optical instrument, contrived by Dr Hook, for representing the image of an object on a wall in a light room, either by day or night, an account of which appeared in the Philosophical Transactions.

Camera Lucida, is also an optical instrument invented by Dr Wollaston of London, for the purpose of enabling those who are not familiar with drawing to take sketches of objects. *Phil. Mag.* vol. xxvi.

CAMERA OBSCURA, is an optical apparatus by which the images of external objects are distinctly exhibited. See Optics.

CAMERONIANS, a religious sect in Scotland, who derive their name from Richard Cameron, a famous field preacher, who refused to accept the indulgences which were granted by king Charles II. because such acceptance was an acknowledgment of the king's supremacy. Cameron, with some of his adherents, was killed in an engagement with the king's troops at Ayrsmoss, in the county of Ayr. His followers were never entirely reduced till the revolution, when they came under a voluntary submission to king William, and a few of the same sect still exist.

CAMOENS, Luis de, the celebrated epic poet of Portugal, was descended originally from a Spanish family of some rank, and was born at Lisbon in 1517; was educated at the university of Coimbra, and being distinguished by his personal accomplishments, he was favourably received at court; from which, being too deeply involved in its dissipation and intrigues, he was banished. He then retired to his mother's house, and began his famous poem on the discovery of India. But having engaged in military affairs, and displayed great bravery in an action with the Moors, in which he lost an eye, he was recalled to court, and again dismissed on account of the suspicions which his gallantry had excited.

With a resolution never to revisit his native country, he sailed to India in 1553, and on his arrival joined an armament of the king of Cochin, destined to make an attack on a neighbouring state, and in this service his military prowess contributed to the conquest obtained, while his poetical talents celebrated the victory. In the succeeding year he accompanied an expedition to the Red sea; and he visited some of those regions of Africa which he has powerfully delineated in the Lusiad. On his return to Goa, he resumed for some time his epic labours; but a satire on the viceroy was the cause of his banishment to China, where he held an official situation for several years, and was successful in the acquisition of a small fortune. But when he was permitted to return to Goa, he was shipwrecked in the passage, and lost every thing except his poems. Misfortune was still the lot of his eventful life; for a new governor of Goa brought a charge of misconduct against him in his public functions at Macao; he was thrown into prison, and, after a public trial, was fully acquitted. But his creditors detained him in confinement, till their demands were satisfied by a subscription among his countrymen. Having regained his liberty, he appeared again in a military capacity, and accompanied the governor of Sofala to that settlement.

After an absence of sixteen years, he returned to Lisbon; but three years elapsed after his arrival, in consequence of the ravages of the plague in that city, before the Lusiad appeared. It was at last published in 1572. The age in which Camoens lived, or the manners of the poet, which seem to have been little accommodated to the prevailing sentiments and opinions, precluded him from that reward to which the author of so splendid a production was entitled. Misfortune and poverty attended him to the end of his days; and, to the disgrace of his country, he was so destitute of the common necessaries of life, that his servant, a native of Java, was obliged to beg in the streets of Lisbon for the support of his master, or, according to another account, the dying poet was compelled to seek an asylum in an alms-house, where death relieved him from his sufferings in 1579, and in the 62d year of his age.

The merits of the Lusiad have been variously appreciated by different critics. Voltaire has charged the author with great incongruity in the nature and management of the machinery which is introduced in his poem; but he is strenuously defended by Mr Mickle, in whose translation the English reader has an opportunity of examining for himself the beauties and faults of this singular production.

CAMP, the ground which is chosen by an army for pitching their tents, in the selection of which the health, accommodation, and safety of the troops are to be considered. See War.

CAMPAGNA DI ROMA, or Campania, is a province of Italy, which has the Mediterranean for its boundary on the south-west, nearly 50 miles in extent, and stretches about the same distance inland. This district, as its name imports, presents a flat surface, to the south of the Tiber it is undulated, but some of the mountains rise to a considerable elevation, as monte Albano, which is nearly 3000 feet, and mount Soracte, which is more than 2000 feet above the level of the sea. The first is about 20 miles and the last about 25 miles distant from Rome. But monte Mario, in the immediate vicinity of the city, rises 440 feet in the centre of the great plain.

The principal strata of these mountains are of a calcareous nature, and a great deal of volcanic productions is scattered throughout the province.

Among numerous sulphureous springs in this province, the most copious are those which issue from the ground between Tivoli and Rome; the water bursts out nearly at the boiling temperature, and forms the lake of Solfatara. These waters are strongly impregnated with calcareous matter, which being deposited on vegetables and other objects, forms incrustations, collected masses of which compose solid strata, that are dug out and applied to architectural purposes. The famous Pontine marshes, which are noticed in the early periods of Roman History, are in the southern part of the province, and have been partially drained at different times, and converted into tillage and pasture lands.

Various kinds of grain, as well as rice, fruits, and other vegetables, are cultivated in this province. Vineyards and olive plantations are extensive, and afford considerable quantities of wine and oil. Flax and hemp are also enumerated among the cultivated productions of Campagna. A great deal of sulphur is collected; and the manufacture of paper and gunpowder afford employment to the inhabitants. Rome, Frascati, Nettuno, Ostia, and Tivoli, are the chief towns.

CAMPANULA, or Bell-flower, a genus of plants belonging to the Pentandria class. See Botany.

CAMPBELL, John, a writer on history, biography, and politics, was born at Edinburgh in the year 1707. His father was Campbell of Glenlyon in Scotland, and his mother, an English lady, claimed some relationship with the celebrated poet Waller. Of his early education little is recorded, and it does not appear that he had the advantage of academical instruction. In his fifth year he was removed from Scotland to Windsor, probably to live with the relations of his mother. He was afterwards placed as clerk to an attorney; but it is said that he was more disposed to literary pursuits than professional business. His first publication, *The Military History of Prince Eugene and the Duke of Marlborough*, (an elaborate production) established his literary character before he had completed his 30th year; and from this time, to the end of his life, he has found few equals in the extent and variety of works of which he was either the sole author or a considerable contributor. In the latter capacity Mr Campbell had a large share in the compilation of the Ancient and Modern Universal History, the first four vols. of the Biographia Britannica, and the Preceptor published by Dodsley, in which Mr Campbell wrote the introduction to chronology, and the discourse on trade and commerce; and in the former may be mentioned the Lives of the English Admirals and other eminent British Seamen, which is still a popular work, and has been continued by others; a concise History of Spanish America; Voyages and Travels; the Present State of Europe, and particularly the Political Survey of Great Britain.

The works now enumerated furnish ample proof of his devotion to literary pursuits, and of the extent and success of his labours. He was remarkable for his temperate and abstemious habits; and his sedentary life scarcely experienced any other variety than a short occasional walk in his garden. His Sunday evening parties were frequented by many who were eminent in science and literature; and learned foreigners experienced the utmost affability, and the most respectful attention, under his hospitable roof. He had received the degree of Doctor of Laws from the university of Glasgow in 1754; and during the latter part of his life he held the office of agent for the province of Georgia in North America. He died in 1775, in the 67th year of his age.

CAMPBELL, George, a learned theological writer, was born at Aberdeen in Scotland, in Dec. 1719, and was educated at the grammar-school of his native place, where his father was a clergyman, and whose early death left his family in no great affluence. Having passed through a regular course of study of the Latin and Greek languages in Marischal college, and being destined to the profession of a writer to the signet, or attorney, he was for that purpose bound an apprentice. But during his residence in Edinburgh in the prosecution of that object, he had turned his views to the clerical office, and, before his apprenticeship had expired, had attended the lectures on divinity in the university. Returning to his native place, he continued the same studies, and in 1746 was licensed to preach. Two years afterwards he was appointed to a country parish in Aberdeenshire, and having spent nine years in this sequestered situation, he was translated in 1757 to be one of the ministers of Aberdeen; and in 1759 was promoted to the office of principal of Marischal college.

Soon after being placed at the head of this seminary, he preached a sermon on the subject of miracles, as a refutation of Mr Hume's celebrated Essay on that subject; but before it was presented to the world Dr Campbell threw it into the form of a dissertation, and, through his friend Dr Blair of Edinburgh, submitted it to the perusal of the philosopher, who ingenuously acknowledged the ability and learning which it displayed, and the liberal manner with which his positions and arguments were treated. In 1771 Dr Campbell was elected professor of divinity in Marischal college, when he resigned his office as one of the ministers of Aberdeen. But he still continued to preach once every Sunday in one of the established churches. It is scarcely necessary to add, that he discharged the duties of his new situation with great ability and with the highest satisfaction to those who had the benefit of his excellent instructions. In the same year he published a sermon on the Spirit of the Gospel, which is much admired; and in 1776 a greater work, *The Philosophy of Rhetoric*, appeared; and about the same time a sermon on the Duty of Allegiance, in reference to the revolt and independence of the American colonies, in which he maintains that they had no right either from reason or scripture to throw off their allegiance to Great Britain, was presented to the world, and while it received the unqualified approbation of one party, was not less unequivocally censured by another. Every liberal mind will readily admit that Dr Campbell was better employed when he published an *Address* *to the People of Scotland*, for the purpose of suppressing the spirit of intolerance which, in the year 1779, burst forth into acts of tumult and disgraceful outrage against the Roman catholics, in consequence of the relaxation of the penal statutes against that body which was then proposed. About the same time he published a sermon on the *Happy Influence of Religion on Civil Society*. The last work which was presented to the world during his life was his Translation of the Four Gospels with preliminary dissertations and explanatory notes. His *Lectures on Ecclesiastical History*, on *Systematic Theology and Pulpit Eloquence*, and on the *Pastoral Character*, were published after his death, which happened on the 31st March 1796. He had resigned his offices of professor of divinity and principal the preceding year, and had a pension of L.300 a-year conferred upon him by government.

Dr Campbell's character was in all respects highly estimable. As a public teacher, he was greatly admired for the clearness and copiousness with which he illustrated the great doctrines and precepts of religion. His numerous works afford ample testimony of his talents and learning. In domestic life, his manners were kind and affectionate; his conversation was unassuming, agreeable, and instructive; and in his opinions and sentiments, whether of a political or religious nature, he possessed that degree of moderation which commands the esteem and regard of all parties.

CAMPBELLTOWN, a borough town in the district of Kintyre in Argyllshire in Scotland, stands on the east side of the peninsula, and about 12 miles distant from its extremity, which projects towards the north coast of Ireland. The bay or harbour, which is about two miles in length and a mile in breadth, with 6 to 11 fathoms depth of water, is spacious and secure. The town, which is situated at the west angle of the bay, was only a fishing village in the seventeenth century, and was constituted a royal borough at the commencement of the eighteenth. The population, which, about the year 1791, was stated at 5000, exceeded 6000 in 1811. Some attempts have been made to introduce cotton and woollen manufactures; but the capital and industry of the inhabitants are chiefly employed in the herring fishery, which at one period proved a very lucrative concern. The elevated grounds in the vicinity command a most extensive and picturesque view of the frith of Clyde, the islands of Arran, Ailsa, and others rising from its surface, and the opposite shores of Ayrshire and Galloway.

CAMPEACHY, or CAMPECHE, a town of Mexico in South America, stands on the east coast of a bay of the same name, is defended by walls and a strong fort, but has of late years considerably declined. The population is stated at 6000; and the chief trade depends on the exportation of Campeachy wood, or logwood, which is produced in great abundance in the surrounding territory.

CAMPHOR, a concrete substance, which is chiefly obtained from the *laurus camphora*, or camphor tree, a native of the warmer regions of the East, and is also secreted from the juices of other plants, as thyme, rosemary, and ginger. See CHEMISTRY.

CANAAN, was, according to the scripture history, the fourth son of Ham and the grandson of the patriarch Noah, who, for the conduct of his father, pronounced the curse, that he should be a servant of servants to his brethren. This prophetic denunciation, and its final accomplishment, have been the subject of much ingenious speculation among Biblical critics and Oriental writers. According to some, the whole race of Ham was included in the malediction; but, according to others, the descendants of Canaan only were subjected to servitude. The descendants of Canaan, or the Canaanites, were partially enslaved by the Israelites; a greater number was brought under the same humiliating condition in the time of Solomon; and during the invasions of the Assyrians and Persians, who were both descended from Shem, they again suffered degradation and subjection.

CANAAN, LAND of, that country which was inhabited by the posterity of Canaan, and which lies between the Mediterranean and the mountains of Arabia, and stretches from Egypt to Phœnicia. This country was afterwards called Palestine, from the people called Philistines, who inhabited the sea-coasts. It was denominated the Land of Promise, because God had promised to Abraham to give it to his posterity; the land of Israel, because it was occupied by the Israelites; the land of Judea, from the tribe of Judah, being one of the most powerful of the tribes of Israel; and, finally, the Holy Land, because the dispensation of the gospel was first promulgated in it.

CANADA, an extensive province of North America, and one of the most valuable colonies subject to Britain, lies between 64° and 90° of west longitude, including a distance of 1300 miles, and at its greatest breadth between 43° and 49° of north latitude. The gulf of St Lawrence forms the boundary on the east; New York, New England, New Brunswick, and Nova Scotia, on the south and south-east; and the Indian territories on the north-west and south-west. It is divided into Upper and Lower Canada; the former of which lies on the north side of the lakes, and is chiefly inhabited by English colonists; and the latter stretches along the river St Lawrence towards the east, and is occupied in a great measure by French settlers.

The surface of this extensive region exhibits some of the most magnificent scenery on the face of the globe,—in lofty mountains, immeasurable forests, immense lakes or inland seas, huge rivers, and stupendous cataracts. Primitive rocks compose the prevailing strata of some of the more elevated districts, and a large proportion of limestone is distributed throughout the province. Granite forms a vast chain along the north side of the great lakes, while they are bounded by calcareous rocks towards the south and west. Some indications of lead ore have been observed, as well as some iron and copper ores.

The lakes of Canada constitute one of the most striking features in the aspect of the country. Lake Ontario, which is about 160 miles in length, and about 450 in circumference, has a depth of water of more than 350 fathoms, and is studded with numerous islands. Lake Erie is 300 miles long, 40 miles at its greatest breadth, and more than 700 miles in circumference; but the depth, it is said, does not exceed 50 fathoms. Lake Huron is of a triangular form, about 250 miles in length, and more than 1000 miles in circumference. This lake is greatly subject to severe tempests, which render its navigation highly dangerous. Lake Michigan is about 280 miles long, 70 miles at its greatest breadth, and nearly 1000 miles in circumference. This lake lies within the American territories; but it communicates by a strait with lake Huron. The lakes now noticed are far exceeded by lake Superior, which is indeed the largest expanse of fresh water on the face of the globe; the length is about 400 miles, its greatest breadth is about 100 miles, and the circumference is nearly 1600 miles. The depth is in many places beyond the reach of soundings; many islands rise from its surface, one of which is 100miles in length and 40 miles in breadth, and between 35 and 40 rivers, some of which are large streams, discharge their waters into this lake. Beside the lakes now mentioned, many others to the westward and northward, occupy a great extent of the surface of Canada.

The rivers are on the same magnificent scale. Of these rivers the St Lawrence is the most conspicuous, and indeed one of the largest streams on the surface of the earth; from its outlet in lake Ontario till it mixes its waters with the ocean, it runs a majestic course of 700 miles. With the astonishing breadth of 90 miles where it joins the Atlantic, it is navigable for the largest ships, 400 miles from its mouth, and for vessels of considerable magnitude as high as Montreal. The waters of the St Lawrence are swelled with numerous tributary streams, of which the Saguenay is an impetuous torrent, three miles in breadth and 150 miles in the length of its course from lake St John; and beside which, the Montmorency, the Chaudiere, and others, would be accounted large when compared with European rivers. The cascades form another remarkable feature in these rivers. The falls of Montmorency where it joins the St Lawrence are more than 240 feet in height; but with less elevation, they are exceeded in the mass of water by the famous cataract of Niagara, between lakes Erie and Ontario, which is 600 yards in breadth, and divided by two islands into three distinct falls, one of which is 160 feet, and another is 140 feet high. The noise is heard at the distance of 15 miles, and the cloud of vapour is seen at that of 90 miles. Volney, who visited and described this stupendous cataract, has some curious speculations on the probability of the rocky bed of the fall, which is limestone, being worn down by the force of the current, and the huge body of waters above inundating the low country. *Views of the United States.*

The domestic animals are similar to those of Europe. The horse is active and hardy; but it must be a fabulous story, fit only to amuse the credulous, that when he travels over the ice, and happens to sink in the weak parts of it, the driver of the sledge strangles the animal, by pulling a rope which is previously thrown around his neck, and having dragged him on the solid ice, has nothing more to do than to unloose the rope, or to bleed the horse, when he springs on his feet, and proceeds with his former vigour on his journey. The dog having some resemblance to the wolf, is an useful animal in this country. He is employed in the chace by the Indians, and is yoked in the sledge by the colonists.

Numerous wild quadrupeds find an asylum in the immense forests of Canada, and many are taken annually for the sake of the fur, which constitutes a valuable commodity in the trade of the province. The bear, the fox, the martin, the otter, and particularly the beaver, with some of the deer tribes, are the chief objects of this commerce. Birds of the largest size and of the most beautiful plumage frequent the woods; fishes of the richest flavour abound in the lakes and rivers; insects, some of which are exceedingly troublesome to the settlers, breed in myriads near the marshes and river banks; and reptiles, particularly the rattle-snake, in Upper Canada, are common.

When this province came into the possession of Britain in 1760 the population was estimated at 75,000; but at that time Upper Canada, which now contains 100,000 inhabitants, chiefly British or American settlers, was not then inhabited by Europeans. The population of the lower province is now stated at 200,000, nine-tenths of whom are supposed to be the descendents of French settlers, and still profess the Roman catholic religion, and are governed by the old French laws.

The chief towns of the lower province are, Quebec, which is the seat of government, and is situated on a high point of land, on the north-west side of the St Lawrence, is strongly fortified both by nature and art, and contains about 15,000 inhabitants; Montreal, which is 180 miles above Quebec, stands on the east side of an island formed by the St Lawrence and the river Outawas, and includes about 6000 inhabitants; Trois Rivieres, which is about half-way between Quebec and Montreal, and contains about 250 houses, and several other large and populous villages. The towns or settlements of the upper province are, Kingston, near the outlet of the St Lawrence from lake Ontario; Yorktown, which is the seat of government for Upper Canada; Niagara, or Newark, at the west opening of lake Ontario; and Queenstown, about eight miles beyond Niagara.

In the climate of Canada the transitions from cold to heat, and from heat to cold, are very remarkable, and dividing by these sudden extremes the year into two seasons, summer and winter. The melting of the snows is immediately succeeded by the heat of summer, and the season of vegetation is only checked by the sudden approach of winter. In summer the thermometer rises to 92° Fahrenheit, and in winter it sinks sometimes as low as 40° degrees below Zero, and the average temperature in December and January, is 22° below the freezing point. Upper Canada enjoys a milder climate; the winter is of shorter duration, the frost is not severe, and sometimes without any fall of snow.

The soil of Lower Canada is of a light, dark loam, of considerable depth, and very fertile; but in Upper Canada the country is more level, has a richer soil, and is better adapted for cultivation. In consequence of the original system of division and settlement of the lands, the farms are of small extent, and the improvements of agriculture have not made great progress. Barley, oats, wheat, and Indian corn are produced in abundance for home consumption, besides affording a superabundance for exportation, particularly of wheat and flour.

The manufactures of Canada are not very extensive. Some iron forges have been established; ship building gives employment to a great number of the inhabitants; sugar is prepared from the juice of the maple tree; tanning is prosecuted in some places on a pretty extensive scale. A large distillery has been established at Quebec, and several breweries furnish ale, not only for home consumption but for exportation.

The commerce of Canada is very valuable. The principal exports are grain, beef, pork, and fish; various kinds of wood, pot and pearl ashes, flax-seed, and the most valuable of all the commodities, furs. Among the imports, are enumerated wines, spirits, sugar, salt, and coffee. For the collection of furs, numerous settlements have been established far in the interior.

The original Indian inhabitants still form a considerable part of the population of Canada, although they have declined greatly in numbers in consequence of the frequent wars between different tribes, and particularly in consequence of the ravages of the small pox, by which whole families and tribes have been swept away. Another cause of the decrease in the numbers of the Indian tribes is, their immoderate indulgence in spiritous liquors.

Canada was discovered in 1495, by John Cabot, who sailed under a commission from Henry VII. of England, but no settlement was made. The French visited the coast about the beginning of the 16th century, and in 1534 took formal possession of the country. After various unsuccessful expeditions, a French naval officer, called Champlain, explored the river St Lawrence, discovered the lake which is distinguished by his name, and, about the beginning of the 17th century, built the city of Quebec. The new colony experienced various changes of fortune, arising from the feuds and dissensions of the native tribes in which it was implicated, or from the injudicious measures of its European governors. Canada, after the brilliant exploits of general Wolfe at the siege of Quebec, and the success of the British arms in other quarters, was finally ceded to Great Britain by the treaty of peace which was concluded in 1763. See Volney's *Travels*, M'Kenzie's *Travels*, and Heriot's *Travels in Canada*.

CANAL, an artificial cut filled with water, by which a navigable communication is formed between different places. See NAVIGATION, INLAND.

CANANORE, a principality and town on the coast of Malabar, where the Portuguese formed a settlement and built a fort in the beginning of the 17th century. It came under the power of the Dutch towards the end of the same century, and soon rose to great commercial prosperity. In the year 1770 it was assigned to its native sovereigns by the Dutch, was afterwards seized by Tippoo Saib, and came into the possession of Britain in 1790. The sovereign, who is a female, pays an annual tribute to the East India Company.

The town of Cananore is situated at the bottom of a small bay, and contains a number of good houses belonging to Mahometan merchants. The territories of this district do not extend more than two miles, presenting a surface of low hills and narrow vallies, with some excellent rice grounds, which are well drained and supplied with water. Pepper, cardamoms, sandal wood, and sharks fins, are exported to Arabia, Bengal, Sumatra, and Surat; and are exchanged for horses, almonds, piece goods, sugar, silk, opium, benzoin, and camphor. Cananore is 15 miles north-west from Tellicherry.

CANARA, a province of Hindostan, which stretches along the Malabar coast, between the 12° and 15° of north latitude, and is from 40 to 80 miles in breadth; has the Mahratta territory on the north, the Mysore territory on the east, the Malabar districts to the south, and the sea on the west. This district, which was in a state of great improvement, and was filled with industrious inhabitants, was subdued by Hyder in 1763, and was transferred to the British in 1799, and has since enjoyed undisturbed tranquillity. Much minute labour and attention are bestowed in the cultivation of the soil, and abundant crops of rice are produced, not only sufficient for the consumption of the inhabitants, but for exportation. Mangalore is the chief trading port, from which pepper, rice, sandal-wood, oil, betel-nut, and iron, are exported to Arabia, and rice, honey, grain, and tobacco to Goa and the Mahratta countries.

This province is divided into two districts, denominated from their position, north and south. The productions of the northern district are, sandal-wood, sugar canes, teak-wood, wild cinnamon, and pepper. The sea coast is chiefly inhabited by the brahmins, who live in villages; and Battecola, Ancola, and Carwar, are the principal towns.

South Canara which lies between the 12° and 14° of north latitude, affords similar productions to the northern division. Some of the hills are covered with thick forests, among which the teak tree abounds; and the inhabitants along the sea coast are chiefly Mahometans. Mangalore and Callianpoor are the principal towns. The population of this district exceeds 396,000, and the population of the northern district is more than 200,000.

CANARY ISLES, a cluster of islands, thirteen in number, situate in the Atlantic ocean, off the north-west coast of Africa, between 27° and 30° north latitude, and 13° and 18° west longitude from Greenwich. Their general character is that of fertility, agreeableness, and salubrity, and their peculiar position offers important advantages of a maritime and commercial nature. They form, therefore, a valuable appendage to the kingdom of Spain, but are far from being cultivated and managed with a zeal and judgment proportioned to their various excellencies. The appearance of these islands seems to indicate their volcanic origin; and it is certain that their common mineralogical structure, the remains of several craters, and the abundance of pumice-stone and other igneous products scattered over their surface, are not unfavourable to such an opinion. To these circumstances it is not improper to add the peculiar richness of the soil, as a con-

Canary isles firmation of their volcanic nature. The climate, though on the whole both healthy and pleasant, is by no means either uniform throughout their extent, or steady at any one place. Towards the coast, a dry and rather sultry air is apt to prevail; whilst inland, and in the more elevated regions, fogs and rainy weather are very frequent. The wet season, or winter, extends from December to March, but frosts are rare, and snow is scarcely known during this period; and, on the other hand, during the summer months, especially from July to September inclusive, the heat is often very intense, and the sky is generally unclouded.

The chief products of the Canaries are, grain, fruits, honey, and wax. Sugar was formerly cultivated to a great extent, but has for some time been neglected; and they are understood to be highly favourable to the growth of cotton and tobacco. They abound in cattle, poultry, and game, and their coasts are plentifully supplied with excellent fish. Their principal export is wine, of which Britain and her colonies are the greatest purchasers. It is of different kinds, but on the whole bears a considerable affinity to that of the adjoining island of Madeira. The population of the Canaries amounts to about 180,000, distributed throughout seven of the islands, the others being uninhabited. They are chiefly of Spanish origin, few if any of the ancient proprietors, named Guanches, remaining as a distinct race, and the Castilian tongue is universally spoken. Besides their commerce with foreign countries and with one another, the inhabitants of the Canaries have several manufactories established among them, as of coarse woollen cloths, linens, silks, gauze, &c.

The seven inhabited islands, which alone merit any particular notice, are Lancerota, Fuerta-Ventura, Canary, properly so called, Teneriffe, Palma, Gomera, and Ferro, or Hiero.

Lancerota is about 26 miles long and 16 broad, of an irregular shape, divided by a range of hills of considerable elevation, which yield excellent pasture, and are interspersed with vallies not very remarkable for fertility. It has several pretty good harbours, and a few towns of no great importance. Its chief products are grain, cattle, and poultry.

Fuerta-Ventura, to the south of the preceding is the largest of the Canary isles, being more than 60 miles long and nearly 20 broad. It is mountainous at its north and south extremities, but presents several beautiful and rich vallies towards the central parts, which are well watered and plentifully studded with woods. The produce of this island is similar to that of Lancerota. It has several anchoring places, but no harbour of much value.

Canary, or *Grand Canary*, which gives name to the whole cluster, is upwards of 30 miles in circumference, and lies to the south-west of Fuerta-Ventura. It is high in the centre, and slopes towards the coast, where there are many plains of considerable extent. It is plentifully supplied with water, and though its soil is light, is extremely fertile, notwithstanding the indifferent cultivation to which it is submitted. In fruits, flowers, roots, and grain, it may vie with almost any spot of equal dimensions in the world. Its capital, the city of Palmas, is the residence of the sovereign power of the Canaries. The buildings in general are elegant, and some of the public edifices have a superb appearance. It is a place of considerable trade, but in this respect is inferior to the capital of the island next to be named.

Canary isles

Teneriffe, a good way to the west of Canary, is nearly of the same size as Fuerta-Ventura. A great part of it is rocky and barren, and near the centre stands the celebrated peak, whose summit, on which there is a volcanic crater, is upwards of 15,000 feet above the level of the sea. This islands forms the common mart for the Canaries, which accounts for its large population, perhaps amounting to 100,000 souls. Santa Cruz, its capital, is a well-built town, possessing a good harbour, and is tolerably well defended by forts and batteries. Teneriffe is peculiarly productive in wine, good seasons yielding from 30,000 to 40,000 pipes, a third of which is Malmsey or Canary sack, a fine rich wine, and the remainder is of a harder nature, not worth more than half the price.

Palma, lying somewhat to the north-west of Teneriffe, is of an oval form, about 24 miles long and 18 broad. In structure it resembles the island now named, and, like it, presents manifest indications of volcanoes. Its chief town is small, but it has a great number of villages.

Gomera, to the south-west of Teneriffe, is smaller than Palma, and likewise of an oval form. It is mountainous but very fertile, and possesses a tolerable good harbour on the south coast, where its chief town is built.

Ferro, which lies still farther to the west, is only about 16 miles long and eight or nine broad. A large portion of it is craggy and rugged, but it has several fruitful spots. It contains only one town and a few villages.

The Canary isles, though known to some of the ancients, who denominated them *Insulæ Beatæ*, or *Fortunate Islands*, were not visited by the moderns till about the middle of the 14th century. At this period the natives, who are imagined to have been descendants of Lybians, driven from their own country on the conquest of the Arabs, were established in separate states, under different princes, and though far from being very refined in their manners, had attained to no inconsiderable degree of civilisation. They were partly idolaters and partly theists, but were universally under the influence of several erroneous opinions as to religion, and much addicted to superstitious observances and ceremonies. Agriculture was little practised among them, but they paid great attention to their flocks and herds, which constituted their chief riches. Like the Indian tribes, they frequently warred with each other, and had acquired great dexterity in the use of certain destructive weapons, as spears, darts, and slings. But though fierce and vindictive, they were noted for fidelity, and a generous regard to some of the common laws and claims of humanity. The intercourse between the sexes appears to have been under very commendable restraints among them, and polygamy was reckoned illegal; but it is singular that they paid little regard to nearness of blood in their marriages, and that they made no scruple of frequently changing their wives on very slight grounds of offence. They had some notion of the practice of medicine, and had made a little progress in a few of the most useful arts. Nor were the important subjects of legislation and criminal jurisprudence entirely unknown in their societies. These and other circumstances appear decisive, either of their comparatively ancient establishment, or their recent secession from an organised but semi-barbarous community. The latter is obviously the more probable opinion, and receives no slight confirmation from the alleged affinity of their language to that of some of the dialects in the African continent.

The French were among the first of the moderns to visit these islands; but soon after the death of John de Betancour, who obtained a grant of them from Henry III. king of Castile, and who prosecuted a scheme for their conquest with no small success, about the beginning of the 15th century, they were annexed to the crown of Spain. Many years, and much blood and treasure, were consumed in subjecting the people to a foreign yoke, and bringing them to the profession of a new religion. Lancerota and Fuerta Ventura appear to have been more easily acquired; Canary long and earnestly contended for its independency; Palma made a short resistance, and was partly gained by fraud; but Teneriffe gave the greatest trouble, and occasioned most loss to the invaders. The reduction of the latter, in the end of the 15th century, by the force under the command of captain Alonzo de Lugo, a brave but unprincipled man, decided the fate of the whole cluster; and since that period they have remained in entire subjection to Spanish power. Nothing but judicious policy and a liberal government are wanting to render them among the most enviable colonies of which any European kingdom can boast.

CANDAHAR, a province of Afghanistan, lies between the 31. and 34. degree of north latitude, and is bounded on the north by the province of Balk in Little Tartary, and on the east and south by Baloochistan. Excepting in the immediate neighbourhood of inhabited places, this province presents the appearance of a desert. The houses are constructed of bricks dried in the sun; and wheat, rice, dates, almonds, and saffron, are enumerated among its productions. The cold is severe during the winter, while the heats of summer are oppressive. The face of the country is rocky and mountainous; fresh water is scarce in many places, but some of the vallies are fertile and luxuriant. The camel and the dog are the principal domestic animals; and among the wild quadrupeds are found tigers, buffaloes, deer, and antelopes. Some parts of the province furnish diamonds. Many of the natives still lead a pastoral and migratory life. This province has been generally considered as part of the Persian empire, but was long subject to the sovereigns of Delhi, till they were deprived of it by Nadir Shah, and it is now subject to the chiefs of Afghan.

CANDAHAR, the capital of the province of the same name, is a fortified town, and is situated in north latitude 33°. The modern city is of a square form, and is included within fortifications of three miles in circumference; and from its position on the great road which connects Hindostan with Persia and Tartary, possesses peculiar commercial advantages. It is abundantly and cheaply supplied with provisions. An extensive plain in the neighbourhood is covered with well cultivated gardens, which furnish excellent fruits, of which the grapes and melons are said to be equal to those of Europe. The distance of Candahar from Delhi is 167 miles, and from Calcutta 2047 miles.

CANDIA, an island of the Mediterranean, lying between the 23° and 26° of east longitude, and about 60 leagues in length from east to west, and 15 leagues at its greatest breadth. The coast is indented with numerous bays, and many of the harbours afford safe anchorage. An elevated ridge called the White mountains, traverses the greater part of the island, and for half the year are covered with snow, the melting of which, in the spring, forms impetuous torrents, which are dried up during the summer. The climate of Candia is celebrated for its salubrity, and the soil is remarkable for its fertility. The sides of the mountains are clothed with extensive forests of pine-trees, and the vine, the olive, and orange, trees, with a great variety of other fruits and aromatic plants, are enumerated among its spontaneous productions. Wheat, barley, lupines, and flax, are mentioned among the cultivated crops; but however suitable the soil and climate, they are neither extensive nor managed with skill.

The population of Candia has been estimated at more than 350,000, composed of four different races of inhabitants,—the descendants of the ancient Cretans, who inhabit the mountainous districts, and still preserve much of their language, and many of their customs,—the Abadiots, the remains of the Saracens, who were masters of the island more than a century, and who still occupy separate villages, and speak the Arabic language,—and Turks and Greeks, who constitute the largest proportion of the inhabitants. The principal manufactures are, soap, of which a considerable quantity is made at the different towns, and a few silk and cotton stuffs. The situation of this island is peculiarly favourable for commercial enterprize; but the Turks, its present rulers, are little disposed to promote or encourage trade. Oil is one of the chief commodities of exportation; to which may be added wine, honey, wax, raisins, almonds, walnuts, chesnuts, lintseed, liquorice-root, and cheese.

The chief towns of Candia are, Candia, the capital, Canea, and Retimo. *Candia*, the capital of the island, stands on a fine plain, which is supposed by some to have been the site of the ancient *Heraclea*, is about four miles in circumference, and strongly fortified. The streets and squares are regular and well built. The harbour, which was once secure and commodious, has been neglected and is choaked up with mud, from which the trade of the place has declined. The population is about 14,000.

Canea lies on the north side of the island, at the extremity of a spacious bay, and is supposed to be the ancient *Cydonia*, is strongly fortified, the streets are wide and regular, and the squares are adorned with fountains. Canea is the most flourishing seaport of Candia. The harbour has been neglected, and the extensive arsenals erected by the Venetians

Candia. for the accommodation of trade, are in a ruinous condition. The population is about 15,000.

Retimo is also a sea-port town about 40 miles west from Candia, was at one time a place of considerable strength, but the fortifications have been allowed to go to decay; the harbour has been also neglected, and, where large vessels were formerly admitted, small craft can scarcely approach.

Candia, which was the ancient *Crete*, was reduced to the dominion of the Romans in the 66th year before the Christian era, and continued to acknowledge their authority till the beginning of the 9th century, when the Saracens invaded the island, and finally became its masters. In the beginning of the 10th century, it was again recovered and restored to the empire; but about the commencement of the 13th century it was assigned to the Venetians, under whom the agriculture and commerce of the country revived and greatly flourished. Candia was attacked by the Turks about the middle of the 17th century, and after a severe struggle was reduced to their authority, under which it has since continued. The inhabitants of ancient Crete have been estimated at 1,200,000, from which it must appear that the population has greatly diminished.

CANDLE-MAKING.

Introduction. THE word *candle*, which is so well known in the domestic economy of civilized nations of modern times, is derived from the Latin verb which signifies *to burn*, and is supposed not to have been unknown to the ancients, although the lamp was more generally employed for similar purposes. Candles are made of various substances, as tallow, wax, and spermaceti; but the first two substances, and particularly the tallow, are in most general use.

Tallow Candles.—Two methods are followed in making tallow candles, namely, dipping or moulding; but by whatever process they are manufactured, the first step is the preparation of the tallow, on which the quality of the candles greatly depends.

The low temperature at which hogs lard melts, and the offensive smell, and dense black smoke which it emits in burning, have excluded it from the manufacture of candles. The tallow of the sheep and the ox is chiefly employed; and the attention of the mafacturer is first directed to select and sort it for the different kinds of candles. For moulded candles, sheep-tallow, with a certain proportion of the best kind of ox-tallow, is chosen. Candles which are made chiefly from sheep-tallow have a firmer texture and a better gloss. For dipt candles, ox tallow, with those pieces of sheep tallow of an inferior quality, is employed.

The tallow being properly sorted, it is cut into small pieces to prepare it for the first melting, which is called by the workmen *rendering*; and it is scarcely necessary to add, that no time should be lost in completing this process, before the tallow become rancid, or undergo any other change; but after the process of rendering, it may be kept in a moderate temperature for a long time, and be improved. Thus prepared, it is thrown into a boiler, and heat is gradually applied; as the tallow melts new portions are added, and the whole is carefully stirred, and after boiling for some time, a cake, called the *crackling*, forms on the surface. This cake is taken out and subjected to strong pressure, to separate any portion of tallow that adheres to it. The liquid tallow is put into another vessel, through an iron sieve, that any fibrous or solid parts mixed with it may be separated.

Preparation. But a farther purification is still necessary; and for this purpose the tallow is put into another vessel with a portion of water, which having a greater specific gravity occupies the lower part of the vessel, and carries with it such soluble impurities as are mixed with the tallow. After the impurities have settled, the tallow is put into tubs and allowed to become solid, after which the entire mass is taken out and piled up, to be used as occasion requires. In removing the tallow from the large vessel to the tubs, a good deal of precaution is necessary not to disturb the impurities which have collected at the bottom.

From this description of the process of rendering, it must be obvious that two objects are in view; the first is to separate all the fibrous and solid parts from the pure tallow, or oily matter; and the second, when the addition of water is made, is to dissolve and separate those substances which still remain mixed with it, and which could not be extracted by the first part of the operation.

Preparation of the wicks.—The wicks of the better kinds of candles are made of fine spun cotton, and it is generally prepared for the candle-maker in the form of skeins, the number of which is varied according to the proposed thickness of the wick, and being wound off into balls or clues, are cut into proper lengths. The wick is then drawn between the finger and thumb for the purpose of smoothing the threads and removing knots or other matters which might hurt the burning of the candles; but this dressing, as it is called, is sometimes not sufficient to keep the wicks separate from each other when they are arranged on the dipping sticks. This inconvenience may be obviated by dipping a number of wicks in melted tallow, and rubbing them between the palms of the hands, while the tallow which adheres to them cools and becomes solid.

Dipping candles.—Those who are attentive to have candles of the best quality employ a mixture of tallow which has been lately rendered with a certain proportion of some which has been prepared for ten or twelve months, although, in some cases, to save the expence of re-melting, the candles are made immediately after the operation of rendering is completed. The tallow being melted in the one case, or before it has cooled in the other, is carefully skimmed and removed from the boiler with small buckets or ladles into the dipping mould, which is a vessel about three feet long, two feet broad, and

Candle-making.

of the same depth; it is lined with lead, and is raised on a frame at a convenient height for the workman. In cold weather, or when the operation of dipping proceeds slowly, some additional heat is requisite to keep the tallow at the proper temperature; and when this is necessary, it is done by placing a chafing dish below the dipping mould.

The tallow being introduced into the dipping mould, and the workmen having placed a certain number of wicks, which is regulated by the size of the candles, on the sticks or broaches, he takes three of them into his hands, and, while they are kept at an equal distance, he immerses the wicks two or three times in the liquid tallow. The rods are then hung upon a rack to cool; and a similar operation is repeated, till the candles assume the requisite thickness. To abridge the labour of dipping, a long lever is employed in some manufactories. To one end of the lever a wooden frame, on which the broaches with the wicks are arranged, is attached, and the opposite arm is counterbalanced by a weight. That extremity of the lever to which the frame is fixed is immediately above the dipping mould, and the lever is so balanced that the wicks may be immersed in the liquid tallow by a slight pressure of the hand. But this apparatus has been greatly improved by constructing a kind of horizontal wheel, which consists of an upright shaft, with twelve arms placed horizontally and at equal distances. A frame which supports six rods, having each 18 wicks, is suspended from the extremity of each arm. The machine is moved by the workman; and each frame, as it comes successively over the dipping mould, is pressed downwards that the wicks may be immersed in the tallow. With some additions to the apparatus, the facility of dipping is improved, and the steadiness of the machine is secured. The process of cooling goes on during the revolution of the wheel; and the time necessary to finish the candles must depend on the temperature of the air. To ascertain the weight of the candles which are required, it is usual for the workman to take one of the broaches from the frame and hang it on the end of a balance, in the opposite scale of which the weight required is placed.

Moulded candles.—As the name imports, candles of this description are cast in a mould. The mould, which is made of some metallic substance, and generally pewter, is a hollow cylinder, open at the extremities, and well polished within. A small metallic cup is soldered to the top of the mould, and through a hole in the cup the end of the wick is drawn. According to the size of the candle to be made, 12 or 16 moulds are fixed in a frame, the upper surface of which forms a shallow trough. The wicks are introduced with a hooked wire passed through the mould, and when the wick is drawn to the other extremity of the mould it is kept stretched, and in the centre, by means of a cross wire passed through the loop. The liquid tallow is then introduced from a cistern by means of a stop-cock, into the trough, and when the moulds are about half filled each of the wicks is drawn tight, that it may be exactly in the centre of the candle, after which the moulds are completely filled; the frame is then set aside to cool, and when the tallow has acquired a sufficient degree of solidity, the small wires which held the wicks secure are withdrawn, a bodkin is introduced into the loop of each wick, and the candle is drawn out of the mould. The candles are then laid up in the storehouse, and if they are kept for some months they acquire the requisite degree of whiteness; but if they are brought to market soon after being made, it is usual to bleach them by exposure to the open air for several days.

Wax candles are either of a conical or cylindrical form, and they are made with a ladle or the hand. By the first operation, the wicks being prepared, and a dozen of them being suspended by the loops at equal distances round an iron circle, the whole is placed over a tinned copper-bason, full of melted wax. A ladle full of the wax is poured gently on the tops of the wicks, and the operation is continued till the candle acquire the intended size. The three first ladlefuls are poured on the top of the wick; the fourth at the height of three-fourths; the fifth at one-half, and the sixth at one-fourth, when it is required to give the candles a conical form. The candles are then taken down, kept warm, and rolled and smoothed upon a walnut-tree table, with a long square instrument of boxwood, smooth at the bottom.

When wax-candles are made by the hand, the wax is softened by working it in hot water, and it is then gradually applied to the wick hung from a hook. Cylindrical wax-candles are also made either with the ladle or the hand; but they are also made by passing a long wick through melted wax, contained in a brass bason, and at the same time through the holes of an instrument like that used for drawing wire, fastened at one side of the bason.

The importance of candles in domestic economy has led to many attempts to improve their manufacture. In all these attempts, the nature of the material, from its different degree of fusibility, must be taken into account. Tallow melts at 92° Fahrenheit; spermaceti at 133°; bees-wax at 142°; and bleached wax at 155°. The combustion is continued by the melting of a portion of the substance of which the candle is made; and hence the quantity of matter consumed, and the light afforded, will depend on the size of the wick and the fusibility of the matter with which it is supplied. The flame of wax is less brilliant than that of tallow; but as it is less fusible the wick can be made smaller; and this affords the advantage, not only of a clear, perfect flame, but from its flexibility it is disposed to turn on one side, and come in contact with the external air, which completely burns the extremity of the wick to white ashes, and thus performs the office of snuffing. We see, therefore, that the important object to society of rendering tallow-candles equal to those of wax, does not at all depend on the combustibility of the respective materials, but upon a mechanical advantage in the cup, which is afforded by the inferior degree of fusibility in the wax; and that, to obtain this valuable object, one of the following effects must be produced: Either the tallow must be burned in a lamp, to avoid the gradual progression of the flame along the wick; or some means must be devised to enable the candle to snuff itself as the wax-candle does; or, lastly, the tallow itself must be rendered less fusible by some chemical process. The wick of a tallow-candle, then, must be made thicker in proportion to the greater fusibility of the material, which would otherwise melt the sides of the cup and run over in streams. It would be an essential improvement, if some addition could be made to tallow which would render it less fusible, because a smaller wick might be employed and the brilliancy of the flame would be thus increased. For this purpose various substances have been tried, such as resins, gums, and saline matters; but it does not appear that any trials which have been yet made have proved successful; although candles thus prepared, or, as they are called, *chemical candles*, are announced by the manufacturer, not only to be more durable, but to burn with a clearer flame. See Nicholson's *Journal*, vol. i.

CANDY, a large district or kingdom of the island of Ceylon, as well as the capital of that kingdom, which is now under the dominion of Britain. See CEYLON.

CANEA, a sea-port town of the island of Candia. See CANDIA.

CANELLA, a genus of plants belonging to the Dodecandria class.

CANNA, or Indian-reed, a genus of plants belonging to the Monandria class. See BOTANY.

CANNABIS, or Hemp, a genus of plants belonging to the Diœcia class.

CANNÆ, an antient town in Apulia in Italy, of which only some fragments of the walls remain, is memorable in history for the battle which was fought near it between the Romans and Hannibal, the renowned Carthaginian general, when the former were completely overthrown, and the republic itself was threatened with ruin. This famous engagement took place in the 536th year of Rome, and 216 years before the Christian era. The loss of the Romans is stated by one historian at 70,000, and by another at 50,000; while the loss of Hannibal is said to have little exceeded 5000.

CANNIBAL, a name applied to a person who feeds on human flesh. Some authors seem to be exceedingly desirous to establish the fact, that cannibals have existed both in ancient and modern times, and have written long dissertations to prove this point. Under the word ANTHROPOPHAGI, or man-eaters, we have ventured to assert, and from farther consideration we repeat the assertion more strongly, that no race of men ever existed, who, from choice, preferred human flesh to other kinds of food; and that in all cases where such a practice has prevailed, it has arisen from necessity, or has been considered as a religious ceremony. Savages, it is true, very generally devour the bodies of their enemies; but it cannot be doubted that it proceeds from a spirit of revenge, or that it is regarded as a sacrifice to their divinities, or an acceptable service to their warriors who have fallen in battle.

CANNON, a military engine for projecting balls by the explosive force of gunpowder. See GUNNERY.

CANOE, a kind of vessel, or boat, which is employed by uncivilized nations. They are sometimes formed from the trunk of a tree of a light kind of wood, as the cotton-tree of the West Indies, which, from its great diameter, allows them to be made of a large size; sometimes they are composed of different pieces of the bark of certain trees, and sometimes they consist of a frame, which is covered with skins. Of the latter description are the Greenland canoes, which are also covered over or decked as it were with the same material, excepting an opening in the middle, in which the navigator places himself, and drawing the skin tight about his body, renders the whole apparatus air tight. The canoe of the Esquimaux who visited Leith last year (1816,) exhibited a fine example of this construction.

CANON, a person who posseses a prebend or revenue appropriated for the performance of divine service in a collegiate church or cathedral. Canons were originally inferior ecclesiastics, who were regarded as the domestics of the bishop, and who assisted in the service of the church. In the progressive history of the church, the canons became in some measure independent of the bishop, and having other functions beside the common office, they assumed all the rights of the other clergy, and made themselves a necessary council of the bishop, taking upon them the administration of the see during a vacancy, and the right of election of a bishop to supply it. Canons are of various kinds, as cardinal canons, or such as are attached to a church; domiciliary canons were such as, not being in orders, had no right in any particular chapters; expectative canons were such as, without having a revenue or prebend, possess the title and dignities, with a voice in the chapter, and a place in the choir, till such time as a prebend should become vacant. Foreign canons were such as did not officiate in the canonries to which they belonged, and to them are opposed canons residentiary. Regular canons are such as live in community, and who have added the solemn profession of vows to the practice of their rules; they are called regular to distinguish them from secular canons, who decline living in community, as well as the observance of rules for the support of discipline.

CANON, is a law or rule, either of doctrine or discipline, specially enacted by a council, and confirmed by the authority of the sovereign. Canons are, strictly speaking, decisions in religious matters, or regulations of the policy or discipline of a church, drawn up by provincial, national, or general councils. Various collections of the canons of eastern councils have been made. Four of these collections are particularly distinguished in church history. The first was made in the year 380, and consisted of 164 canons; the second, composed in the year 520, received the addition of 50 canons of the apostles and those of the other general councils; to the third were added the canons of the council of Sardica and of the

African councils; and the fourth includes all the canons down to the second council of Nice.

Canon signifies also the authorised catalogue of the sacred writings. See SCRIPTURES.

CANON LAW, a body of law which was promulgated by the see of Rome for the regulation of all matters, whether civil or ecclesiastical, relative to the members of the church subject to its authority. The body of the canon-law, or *Corpus juris canonici*, was revised and published by Pope Gregory XIII. and is composed, first, of a selection called the *Decretum*, of the opinions of the fathers, popes, and church councils, which was made in the 12th century; second, of the *Decretalia*, or rescripts of later popes; thirdly, of another collection of decretals; and fourthly, of a still later collection called *Extravagantes*, because they are in addition to the six books of the decretals.

CANOPUS, an ancient city of Lower Egypt, which stood near the place now occupied by the modern Aboukir. The massy colums of granite, and other splendid fragments which must have belonged to spacious edifices, afford abundant proofs of its ancient magnificence.

CANOSA, the ancient *Canusium*, is a town of Naples in Italy. The ancient city seems to have occupied an extensive plain, in which fragments of columns, aquæducts, amphitheatres, tombs, and baths, and the remains of two triumphal arches, are sufficient proofs of its former grandeur. The modern town is only remarkable for its cathedral, among the internal decorations of which are six fine columns of verde antico.

CANOUGE, or KANOGE, a district in the province of Agra in the East Indies, which extends along the eastern banks of the Ganges, is distinguished by a sandy soil, which is well cultivated, and by the abundance of Mango clumps or groves: to prevent the failure of the crops, when the rains are deficient, the fields are watered from wells by the industry of the inhabitants.

CANOUGE, is a town in the province of Agra, stands about two miles distant from the Ganges, with which it has a communication by means of a canal, and lays claim to great antiquity and celebrity. It was the capital, according to the Hindoo histories, of a powerful empire, which existed at the period of the Mahometan invasion, and, in the exaggerated relations of its extent, is said to have been a hundred miles in circumference. A single street is all that remains of this ancient city; but over a space of six miles, fragments of bricks, and vestiges of buildings, still mark the space which it occupied; and the tombs of two Mahometan saints, which are enclosed in two mausoleums, surrounded with trees, form conspicuous objects on an elevated situation. Canouge is 75 miles from Lucknow, and 719 miles from Calcutta.

CANTAL, a department of France, which has for its boundaries on the north and west the departments of Puy de Dome and Correze and Lot, and on the south and east the departments of Lozere and Upper Loire, is situated in the middle of the mountains of ancient Auvergne, one of which rises about 3000 feet above the level of the sea. The population exceeds 237,000, and a large proportion of the inhabitants is occupied in the dairy husbandry, of which cheese is the most abundant production and the chief commodity of their trade. Marl and slate are dug out in some places, and mines of copper and antimony have been opened. Aurillac is the chief place of this department.

CANTATA, a musical composition, intermixed with recitatives, airs, and different movements, chiefly intended for a single voice, with a thorough bass, though sometimes for other instruments.

CANTERBURY, an ancient city, capital of the county of Kent, and the archi-episcopal see of the primate of all England. See KENT.

CANTHARIDES, Flies which are formed into a plaster for producing blisters on the skin. The species of fly used for this purpose is the *meloe vesicatorius*, a native of Spain, and hence called the Spanish Fly. The specific name, it is obvious, is derived from its effects.

CANTON, a city of China, and capital of the province of Quang-tong, and the sea-port to which the trade with Europe is exclusively confined, stands on the eastern bank of the river Pe-Kiang, from which there is a navigable current for 300 miles into the interior of the kingdom. It is surrounded with walls, which are about five miles in circumference, and are surmounted with a few cannon, but the fortifications are little calculated for a vigorous defence. Canton is in north latitude 23° 7′, which is nearly the same parallel with Calcutta, yet the former enjoys a cooler temperature, and even requires fires during the winter months.

The streets of Canton are very narrow, paved with small round stones, and flagged close to the sides of the houses; but of the space within the walls a large proportion is appropriated to pleasure-grounds and fish-ponds. The suburbs are still more extensive than what is included within the fortifications, the gates of which no European is permitted to enter; and in these suburbs the streets are long and narrow, but regular and paved, kept very clean, and adorned at intervals with a kind of triumphal arches, and sometimes covered with an awning, extending from house to house, to protect the inmates from the rays of the sun. Each side of these streets is entirely occupied by shops, where all kinds of commodities and manufactures are exposed to sale. Some of the streets are solely possessed by particular trades, but in others no restriction is observed. The houses, which are generally built of brick, rarely exceed two stories in height, excepting the mansions of the mandarins and wealthier merchants, which are lofty and elegant. Numerous temples are erected both in the city and suburbs, and the palace of the viceroy is a large building, not destitute of magnificence.

The foreign factories, which extend a considerable way along the banks of the river, form the most beautiful part of Canton. Each is distinguished by the flag of its own nation displayed before it. The British factory is the most conspicuous both for elegance and extent. The whole are arranged on a fine quay, with a broad parade in front, which form a commodious walk for the European merchants, commanders, and officers of ships, who meet after dinner and enjoy the cool of the evening. In the neighbourhood of the factories, warehouses are erected for European goods before they are sold, or for the productions of China.

For the space of four or five miles opposite to Canton the river resembles an extensive floating city, consisting of boats arranged in regular rows, and leaving a passage in the middle for vessels. A whole family is lodged in each boat, which is covered; and, beside this, they have a smaller boat, in which they fish or go on shore to follow their employments. Not fewer than 300,000 individuals, chiefly of the poorer classes of the Chinese, or the descendants of the Tartars, live upon the water, and, indeed, are not permitted to settle on shore. The population of Canton must be very considerable, although no correct estimation of it is known to Europeans.

Provisions and refreshments of all kinds, and of an excellent quality, are abundant at Canton, and are to be had at a moderate price. The numerous canals and rivers, which intersect the country, furnish plenty of fish; large ponds are stocked with gold and silver fish; and in the butcher market are to be seen horse flesh, dogs, cats, foxes, and owls.

The intercourse with China by the way of the Cape of Good Hope commenced in 1517, when a fleet of eight Portuguese ships arrived with an ambassador, who made a visit to Pekin, and succeeded in obtaining permission to establish a trade at Canton. Some English ships visited Canton in 1634; but, through the jealousy of the Portuguese, it is supposed, a misunderstanding took place, which was followed by open hostilities. In 1667, the court of directors requested their agent at Bantam, in Java, to send home 100 lbs. of the best tea. Two years afterwards another quantity was received by the way of Bantam; and in 1678 the importation of 4713 lbs. of tea seemed to have glutted the market, for the imports for the six succeeding years amounted only to 410 lbs. The first ship sent by the East India company direct to China, sailed in 1680; since which period the trade, with some slight interruptions, has progressively increased.

The imports into Canton by the East India company are chiefly woollen stuffs, lead, and tin; the amount of the first, in the year 1809, exceeded L.877,000 sterling, and the total value of all the imports for the same period was more than 1000,000; cotton, opium, piece goods, pearl, saltpetre, sandalwood, shark-fins, and grain, are brought from British India; and the commodities from foreign Europe, and from America, are of a similar nature to those from England, but smaller in quantity. The principal exports from Canton are tea, china-ware, gold in bars, sugar, sugar-candy, rhubarb, snake-root, sarsaparilla, leather, japanned copper, varnished and lacquered ware, drugs, leaf gold, utensils of white and red copper, cast iron, raw and wrought silk, nankeens, mother-of-pearl, gamboge, quicksilver, red lead, vermilion, and toys. In 1809-10, the cost and charges on goods exported from Canton by the East India company, amounted to L.2,378,883 sterling, and sold in England for L.3,723,116. The quantity of tea disposed of at the East India company's sales in 1810, amounted to 24,540,923 lbs. the duty on which was L.3,548,800. The tea shipped on board British ships in 1806-7 amounted to 32,683,066 lbs. and, including what was carried off by American ships and others, the whole quantity exported was nearly 44,000,000 lbs.

CANTON, John, an ingenious experimental philosopher, was a native of Gloucestershire, and was born in 1718, discovered in early life a strong bias to mathematical learning, and having been removed from the school of his native place to be initiated in his father's business, which was that of a broad cloth weaver, he still devoted his leisure hours to physical studies. With no other instrument than a common knife he constructed an upright sun-dial, on which, beside the hour of the day, were shewn the rising of the sun, and his place in the ecliptic. Although this ingenious production was the labour of late hours, which his father had positively prohibited, yet, with his permission, it was put upon the front of his house, where it attracted the notice of some gentlemen of the neighbourhood, and introduced the young philosopher to their acquaintance. Through their kindness he obtained books and a pair of globes, the first he had seen; and with this essential aid he made rapid progress in various departments of natural philosophy.

Among others of scientific attainments, young Canton was fortunate in obtaining the acquaintance and friendship of Dr Miles, a dissenting clergyman at Tooting, through whose recommendation he visited the metropolis, and engaged as assistant to Mr Watkins, the master of an academy in Spital square; when the period of his engagement had expired, he was assumed as a partner in the institution; and, on the death of Mr Watkins, succeeded to the academy, in which he continued during the rest of his life.

About this time electrical investigations, and particularly the nature of the Leyden phial, which was then discovered, greatly occupied the attention of philosophers. Mr Canton made numerous experiments on the subject, particularly with a view of determining the quantity of electricity accumulated in the phial. In 1749 he assisted his friend, Mr Benjamin Robins, in a series of experiments, to ascertain to what height rockets ascended, and at what distance their light may be seen. In 1750 he communicated to the Royal Society a method of making artificial magnets, without the use of natural magnets, and of greater power, a method which had been kept secret by another philosopher. Two years afterwards he repeated Dr Franklin's experiment of drawing electricity from the clouds; and in the succeeding year he communicated to the Royal Society an account of his electrical experiments, in which he remarks, that the clouds were sometimes in a positive, and sometimes in a negative state of electricity. Beside many other experiments on electricity and its kindred phenomena, he made observations on the transit of Venus; discovered a method of making phosphorus, which imbibes and emits light like the Bolognian stone, and which is still known by the name of Canton's phosphorus; and investigated the nature of the luminous appearance of the sea, which he supposes is produced by the putrefaction of its animal substances. He died in 1772, in the 54th year of his age.

CANTYRE, the southern division of Argyllshire in Scotland, stretches about 37 miles from north to south, is about seven miles in breadth, and terminates in the head land or promontory called the Mull of Cantyre.

CAOUTCHOUC, India rubber, or elastic gum, a substance obtained from different trees in South America, and particularly from the *hevea caoutchouc* and *jatropha elastica*. It has been also obtained from some other trees in the East Indies. See CHEMISTRY.

CAP and BUTTON are two small islands which derive their names from their peculiar shape, and which are situated near 6° of south latitude, and 106° of east longitude; are described as presenting, at first sight, the appearance of old castles and ruinous towers, and seem to have been thrown up by the action of volcanoes. These islands were visited by Sir George Staunton; and in the caverns of the rocks were found great numbers of swallows nests, which are in so much request in China. The nests are are placed in horizontal rows at different depths, from 50 to 500 feet. Their value is chiefly determined by the uniform fineness and delicacy of their texture. Such as are white and transparent are most esteemed, and produce their weight in silver in the Chinese market. It is said that the birds are nearly two months in preparing their nests, and when the young birds are fledged, the nests are collected, and this is repeated regularly thrice a year. The inhabitants who are engaged in this business descend into the caverns by means of ladders of bamboo and reeds; but this, like the bird-catching of our own country, is a very hazardous occupation.

CAPE BRETON, an island separated from Nova Scotia by a narrow strait on the east coast of North America. See BRETON.

CAPE OF GOOD HOPE, a colony belonging to Great Britain, on the southern extremity of the continent of Africa, lies between the 17° and 28° of east longitude, and the 29° and 35° of south latitude. The ocean forms its boundary on the south and west, the Great Fish river and Caffre land on the east, and the country of the Bosjesmans on the north. The length, at an average, is stated at 550 miles, the breadth about 230, and it includes a superficial area of more than 130,000 square miles. But a great extent of this surface is covered with naked mountains, or barren plains. Three elevated ridges traverse the country from east to west; the first stretches along the coast, at the distance of from 20 to 50 miles from the sea; the central range, called the Black mountain, runs in a parallel course, and is still higher and more rugged; and the most northerly ridge, rising, it is supposed, to the height of 10,000 feet above the level of the sea, has its loftier peaks covered with snow in the winter season. The elevated ridge which stretches northward from the Cape, terminates in Table mountain, which is more than 3,500 feet above the level of the sea, and two other mountains, which are known by the fantastic names of Devil's-hill and Lion's-head, the first of which exceeds 3300 feet, and the last is about 2160 feet in height. Granite forms the base of all these mountains, and is succeeded by a horizontal stratum of siliceous sandstone, which again is covered by a dark brown sand stone, in which iron ores are disseminated, and the whole is surmounted by a mass of granular quartz, of 1000 feet in height in some places. Parallel ridges of blue compact schistus, but it is not said whether it is micaceous or argillaceous, probably the latter, run from north-west to south-east, and are covered with a body of strong clay, in which are imbedded large blocks of granite. Beautiful agates are found among the decomposed rocks; and *prehnite*, deriving its name from Colonel Prehn, was first discovered at the Cape by that gentleman.

Many of the rivers, which are impetuous torrents in the rainy season, leave their channels dry during the rest of the year. But some of them have a more permanent duration, as Elephants-river, Mountain-river, Broad-river, which is a mile in breadth where it mingles its waters with the ocean, and Great Fish-river, which runs a course of more than 200 miles, and forms the eastern limit of the colony. The coast is indented by numerous bays, of which the chief are, False-bay, Table-bay, and Saldanha-bay, and the last affords good anchorage, and is safe and commodious.

The climate of the Cape is reckoned, on the whole, salubrious; but the sudden changes have a powerful effect on the animal frame. The winds, particularly from the south-east, blow with great violence during certain seasons; thunder storms are frequent; and the rains fall in copious torrents. These winds blast and wither the vegetable kingdom, and are not less baneful in the relaxation of body and mind which they produce on the inhabitants.

A stiff clay, or light sand, is the prevailing soil throughout the colony; and, where it is moistened with water, is invariably covered with luxuriant vegetation. But a great extent of the surface is destitute of springs or rivers; and for great part of the year being rarely visited by a shower of rain, presents nothing but a dreary waste. Such are the plains called *Karroo*, of which the Great Karroo, about 300 miles long and 80 miles broad, has never seen any human being a permanent occupant of its barren sands. But when the rains fall, a vast profusion of vegetation soon appears. These plains are the native seats of many of the succulent plants, and particularly of the curious tribe of *Stapelia*, called, from its remarkable power of resisting the effects of long drought, but with little propriety, the *camel of vegetables*. Between the southern range of mountains and the sea, the soil is deep and fertile, is refreshed by frequent showers, and is covered with luxuriant herbage or lofty woods; in the eastern districts the fertility increases; and the banks of the Great Fish-river presents much variety of rich and beautiful scenery.

Among the wild animals of the Cape, some of the fiercer and larger quadrupeds are conspicuous, as the lion, the leopard, panther, and tiger-cat, the hyena, wolf, and jackal, the zebra, the gnu, many species of antelope, the buffalo, the elephant, the rhinoceros, and the hippopotamus; among the feathered tribes are, the ostrich, flamingo, and spoonbill, with an endless variety of smaller birds, adorned with plumage of the richest and most beautiful colours; and the surrounding seas abound with excellent fish. The botanist need not be informed of the vast profusion of vegetable riches which this territory can boast of, when he recollects how many of the splendid inmates of the stove and conservatory are natives of the Cape. All the rich fruits of tropical climates are abundant. Horses, cattle, sheep, and goats, are the principal domestic animals; and among the sheep is that remarkable variety with broad tails, which are from six to ten pounds weight. It appears somewhat singular, that the number of hogs reared in the colony is very small.

The whole colony is divided into five districts, the total population of which, including Europeans and their descendants, slaves, and Hottentots, or native inhabitants, is estimated at 62,000; but this is exclusive of British settlers. Agriculture is in a very rude state, but wheat, barley, and rye, of which the first is in the largest proportion, are raised in the cultivated districts. The culture of the vine is also an object in many places, and the famous Constantia wine is the produce of two vineyards about eight miles distant from Cape-town. The annual quantity of this wine is from 10,000 to 15,000 gallons. In other districts the rearing of cattle and sheep is the sole occupation of the inhabitants. Many of those who are thus engaged have no settled habitations, but move from place to place as the pasturage for their herds and flocks is exhausted. This class of the population is described as being peculiarly rude in their manners, and severe and cruel towards the Hottentots who are in their service.

While the Cape of Good Hope was under the dominion of the Dutch, its commerce was extremely limited. No trade was permitted with any other but Dutch ships, so that many of the commodities which the inhabitants required were procured by smuggling from such foreigners as touched there for refreshments. Grain, wine, brandy, hides, dried fruits, aloes, and ivory, are the principal exports; but it can scarcely be doubted, as has been suggested, and strongly urged by Mr Barrow, that this colony, from its favourable situation, and the nature of its productions, with proper encouragement and prudent management, holds out the most valuable commercial advantages. Beside the British manufactures, tea, coffee, sugar, spices, rice, and piece goods, are imported from India and China; deal planks, staves, salt fish, pitch, and turpentine from America; iron, timber, French wines, preserves, and pickles, from the northern states of Europe.

For the management of the affairs of the colony, a governor is appointed, as for other foreign settlements, by the king; but its internal police, with regard to civil matters, is regulated chiefly by the laws formerly established by the Dutch; and the constitution of the courts of justice remains nearly the same as in the time of its former possessors. The established form of religion is Calvinistic, and the clergy are paid by government. Different missionary establishments, for the conversion of the natives to Christianity, have been attempted; but after a great expenditure of time and money, none has succeeded excepting the Moravians, who have judiciously commenced their labours by training their followers to habits of industry, and instructing them in useful trades.

The Cape of Good Hope was discovered in 1487, by Bartholomew Diaz, a Portuguese navigator, who, from the tempestuous weather which he experienced, called it the *Stormy Cape*; but, in the prospect of proving a passage to the East Indies, it received its present appellation from the king of Portugal; and ten years afterwards this expectation was fulfilled by another Portuguese navigator, Vasco de Gama, who doubled the Cape, and reached the coast of Malabar. The attempts of the Portuguese to establish a colony failed, and no settlement was made at the Cape till 1650, when a Dutch colony, after treating with the natives, took possession of the peninsula, and founded the present town. The colony received a considerable accession by a number of French refugees, who in 1685 were compelled to quit their own country on account of religious persecution. This colony did not altogether escape the baneful effects of the French revolution. The preposterous sentiments which then prevailed, and the dazzling but false hopes of liberty and equality, had begun to spread among all ranks of the inhabitants, and were about to be put in practice, when the arrival of a British fleet in 1795 turned their attention to other objects. After a slight opposition it surrendered to the British forces, and soon rose to considerable commercial prosperity. It was restored to the Dutch by the peace of Amiens in 1802, but was retaken by the British in 1806, and, by those who have had the best opportunities of appreciating its advantages, is considered a most valuable accession to the colonial territory of Britain, not only as a military, naval, and commercial station, but as the means of securing her Indian possessions against the danger of invasion from the hostile powers of Europe.

Cape-town is the capital of the settlement, stands at the western corner of Table-bay, on a plain with a gentle declivity, and, excepting towards the sea, is surrounded by mountains, is traversed by a considerable stream, and many of the streets, which are spacious and regular, have canals whose banks are adorned with trees; the houses are generally of stone, and two stories in height, and the squares are also spacious and commodious. The castle, to the eastward of the town, is a place of strength, can accommodate 1000 troops with their stores, and includes within its walls the public offices. The barracks, a large edifice, can admit 4000 men; and the courts of justice, the theatre, the guard-house, and the churches belonging to the Calvinists and Lutherans, are the principal public buildings. On the side of Table-mountain stands the government-house and the public garden, of 40 acres extent, part of which is laid out as a botanic garden; and in the same quarter the wealthier merchants have elegant country-houses.

The population is estimated at more than 15,000, of which one-third is composed of whites and persons of colour; the rest are blacks, and a large proportion is in the condition of slaves, either from the east or west coast of Africa, or from the Malay islands. The inhabitants are charged with indolence, and debauchery in smoking and drinking;

it is scarcely to be expected that they should have much ardour in literary pursuits; but it is surprising that they are so phlegmatic as to exclude all relish for public amusements. Exclusive of European and Indian luxuries, living is upon the whole moderate. The necessaries of life, as well as all kinds of vegetables for the table, and excellent fruits, are abundant and cheap. Vaillant's *Travels*, Barrow's *Travels*.

CAPE VERD ISLANDS, a cluster of islands in the Atlantic ocean, about 400 miles west from Cape Verd in Africa, and between the 15° and 18° of north latitude. This groupe, which is composed of ten or twelve islands, some of which are not yet inhabited, was discovered in 1449, by a Genoese in the service of Portugal. Most of the islands are mountainous and rugged, but the vallies are fertile, and the less elevated districts are clothed with rich verdure. Water is not abundant, and rain is not frequent. The fruits of tropical regions are plenty; and rice, Indian corn, grapes, cotton, and indigo, are enumerated among the cultivated productions. Great numbers of goats, hogs, mules, and cattle, are reared, with some of which ships are supplied in their outward bound voyages. The number of inhabitants is estimated at 100,000, the greater proportion of which is composed of negroes and persons of colour. The proportion of whites is said to be very small.

CAPIAS is a law term applied to two kinds of writs, one before and the other after judgment in an action. Before judgment it is called *capias ad respondendum*, where an original is issued out to take the defendant, and make him answer the plaintiff. After judgment it is distinguished into different kinds, as *capias ad satisfaciendum*, which is a writ of execution that issues on a judgment obtained, where any person recovers in a personal action, and is directed to the sheriff to secure the person of the debtor till he make satisfaction. *Capias pro fine* is a writ lying where a person is fined to the king, and is imprisoned till the fine be paid. *Capias utlegatum*, a writ which lies against an outlaw, and directed to the sheriff to apprehend and secure the party till the day of return.

CAPILLARY, derived from the Latin word signifying *hair*, refers to something which is extremely fine, as *capillary* tubes of glass, which are as fine as hair, and *capillary attraction*, which denotes the ascent of fluids in such tubes higher than the surface of the fluid in which they are immersed, a subject which has long occupied the attention of philosophers, and of which no satisfactory solution has been yet proposed.

CAPO D'ISTRIA, a sea port town of Istria, in the gulph of Trieste, and situated on a rock or island, about half a mile distant from the continent, with which it communicates by means of a causeway. It is two miles in circumference, and is the see of a bishop; is adorned with a cathedral, numerous churches and convents; and its chief trade consists of wine and salt. It is eight miles south from Trieste.

CAPPADOCIA, a district or province of ancient Lydia in Asia, seems to have performed a conspicuous part in its struggles with the Persians, the Greeks, and the Romans; became at last dependent on the Roman authority; and in the beginning of the thirteenth century was reduced to the dominion of the Turks, under whose power it still remains, and is distinguished by the modern appellation of Amasia, from a city of the same name which is situated in the province.

CAPPARIS, the CAPER-BUSH, a genus of plants belonging to the Didynamia class, the buds of one species of which, preserved with vinegar, form the well known and agreeable pickle which is annually imported from Italy.

CAPRI, or CAPREÆ an island on the south side of the bay of Naples, about three miles distant from the coast, about eight miles in circumference, and somewhat of a triangular form; exhibits, in the precipitous cliffs, and large masses of rock, a rude and barren aspect; but examined more nearly, spots covered with rich verdure, and studded with houses, are seen. The prevailing strata are limestone. The chief towns or villages are Capri and Anacapri, the former situated on a fertile spot, between two lofty rugged rocks, and the latter, which consists only of a few streets and detached houses, is surrounded with groves of fruit trees, and excellent gardens. Capri is famous for being the luxurious retreat of the Emperor Tiberius, and numerous ruins and fragments of buildings are still visible.

This island is not less remarkable, in modern times, for the prodigious number of quails and stock-doves, particularly the former, which are annually taken, and from which the bishop derives a large proportion of his revenue. In good years, 60,000 quails are sometimes caught; and it is said, that the extraordinary number of 45,000 was taken in a single day.

CAPRICORN, one of the twelve signs of the Zodiac. See ASTRONOMY.

CAPRIFICATION, a method of ripening the fruit of the domestic fig-tree, which is practised in the Levant and Greek islands, by means of the insects which are bred on the wild fig-tree. In the months of May and July, the peasants collect the insects from the wild fig, and place them on the cultivated fig-trees, the fruit of which is wounded by the insects, for the purpose of depositing their eggs, and in this way, the growth of the fruit being interrupted, it comes sooner to maturity; on this the whole process depends. Endless speculations have been indulged by physiologists on this subject; but where the climate is favourable, no advantage can follow such a practice, and hence, as the consequence of more accurate observation, it is said to be discontinued in some of the Greek islands; and in Malta it is followed only for the purpose of bringing the later crops of figs to maturity.

CAPRIMULGUS, the GOAT-SUCKER, a genus of birds. See ORNITHOLOGY.

CAPSICUM, or GUINEA PEPPER, a genus of plants belonging to the Pentandria class.

CAPSULE, in its general meaning, signifies a receptacle or cover, in the form of a bag; and, in botanical language, it is applied to a seed-vessel or pericarpium which divides or splits in a determinate manner. See BOTANY.

CAPTION, in the law of England, is a certificate which relates to commissions to take fines of land, to take answers in Chancery, or depositions of witnesses, and in which the time and place of executing the commission must be declared and subscribed by the commissioners.

Caption, in the law of Scotland, is a writ issued under his Majesty's Signet, and in his name, obtained at the instance of a creditor in a civil debt, commanding messengers at arms and other officers to apprehend and imprison the person of the debtor until the debt be paid. Peers, married women, and pupils, are protected by law against personal execution by caption in civil debts.

CAPUA, a city of the province of Lavora in Naples, stands on the bank of the river Volturno, about twelve miles distant from the sea. The modern town is about two miles distant from the site of ancient Capua. The streets are spacious, and the houses are not destitute of elegance; and, beside the cathedral, it has a number of convents and parish churches. The town is well fortified, and contains about 8000 inhabitants.

CARABUS, the BEETLE, a genus of insects belonging to the order Coleoptera. See ENTOMOLOGY.

CARACALLA, MARCUS AURELIUS ANTONINUS, the Roman emperor, received this appellation from a peculiar garment which he usually wore, flourished about the beginning of the third century of the Christian era, was peculiarly distinguished for his ambition and cruelty in aspiring to supreme power, and of which the first striking example which he exhibited, was the murder of his own brother Geta, in the arms of his mother, and by the hands of assassins, while he himself witnessed the bloody deed, and of his brother's domestics and friends, without distinction of rank, age, or sex; it is said that not fewer than 20,000 were the victims of his barbarous cruelty; but after a short reign of six years, and only in the 29th year of his age, he was assassinated by one of his own officers. See *Gibbon's History*.

CARACCAS, a captain generalship of Spanish America, is situated between the 4° and the 12° of north latitude, and is bounded by the Caribbean sea on the north, by the Atlantic ocean on the east, by Dutch Guiana on the south, and by New Grenada on the west.

General aspect.—Washed on two of its sides by the waves of the Atlantic ocean, traversed throughout its whole extent by highly elevated, and thickly wooded mountains, covered at intervals by expansive lakes studded with islands, intersected in every direction by numberless and noble streams, and dilated in many places into wide savannahs, teeming with vigorous vegetation, this north eastern part of *Terra Firma* presents an appearance not inferior in point either of real magnificence or wild variety to any of the regions of the sublime continent of South America, and is superior to some of them in fertility of soil and salubrity of climate.

Mountains.—A range of lofty mountains, branching off from the main chain of the Andes, in the territory of Quito, extends across the whole of this country to the shores of the Atlantic. This range sends off both to the south and to the north many ramifications, so that the whole district exhibits all the grandeur and picturesque effect of mountain scenery. The mean height of the principal chain is about 8000 feet above the level of the sea, and it extends to the breadth of 50 miles across its summit, in which there are extensive tracts of table land, susceptible of the highest cultivation, and affording abundance of pleasant places for habitations. But some of the points of these mountains ascend to a sublimer height, and, from their rocky steepness and their extreme cold, equally resist the hand of culture, and repel the approach of man.

Rivers.—Multitudes of streams rush with great impetuosity from the mountains, and roll in stately grandeur through the vallies of this highly diversified country; and in their course tend towards either the Caribbean sea on the north, or the great river Oronooko on the south. Of the streams that seek the Caribbean sea are the Guigues, the Tocuyo, navigable 40 leagues from its mouth, the Yaracay, the Tuy, winding through delightful vallies, the Urana, which divides the province of Caraccas from that of Cumana, the Nerveri, and the Mazanari. These and many more of less note which water the northern side of the country, and open a communication with its interior, are confined within high banks, which they seldom overflow. The southern declivity of the principal mountainous range which traverses this country, is also well watered by frequent streams; such as the Apura, the Mamo, the Pariagoan, the Pao, the Zoa, the Chivata, the Cachimao, the Aracy, the Marapira, and the Espino, which, though magnificent rivers, pour their tributary waters into the still more magnificent Oronooko, that in majestic grandeur flows with a rapid career from the Andes through wide savannahs, till, by a multitude of mouths, forming a labyrinth of swampy isles, it falls into the Atlantic.

Lakes.—Of the numerous expanses of stagnate water with which the surface of this country is interspersed, two only, the Maracaybo and the Valencia, have been particularly described. The Maracaybo in form resembles a bottle, with the neck communicating with the sea; it is situated at the western extremity of the country, 150 miles in length, and 90 in breadth. Though open to the sea, its waters, except when agitated by the north wind which blows in the brine, are fresh enough to be drank. The banks are barren, and exhale noxious vapours, destructive of animation when long exposed to its deleterious influence; and at Mena, on the north-eastern border, they blaze nightly with phosphoric fires, which serve to direct the course of those who navigate its waters. Valencia is 40 miles in length and 12 in breadth; and though it receives the waters of twenty rivers, it has no visible outlet. The valley in which this lake is situated, the sloping sides of the hills by which it is surrounded, and, still more, the islands which seem to repose on its bosom, constitute a scene of picturesque beauty, similar, it is said, to that of Loch Lomond in Scotland.

Minerals and metals.—The researches of the scientific and enterprising Humboldt, first unfolded the mineral riches of this region. According to him, the mountains are composed chiefly of calcareous strata, resting on a base of primitive rocks. The salt-pits

Caraccas. of the province of Venezuela, supply great quantities of this mineral, of the most beautiful whiteness. Mineral springs, both hot and cold, are also common. The heat of the springs found in the vallies of Aragua, raises the thermometer nearly to the boiling point. These mineral waters possess medicinal qualities.

The first object of Spain, in colonizing America, was the discovery of gold and silver; and with this view the country of Caraccas was early and anxiously explored by her avaricious adventurers. After much search, the wished-for gold was found; but from the insubordination of the negro slaves, and the hostility of the Indians, the mines never could be worked to any extent. Though, however, the Spaniards have been comparatively unsuccessful in their attempts to obtain the gold and silver deposited in this country, they possess, in the jurisdiction of St Philip, copper mines, from which they obtain copper for the implements required by the planters, and have a surplus for exportation.

Pearls.—The first settlers in this country were consoled, and in a great measure compensated, for the want of the precious metals, by the discovery that its coast contained abundance of valuable pearls. The shoals which extend from Cape Paria to that of Vela, the island of Margaretta, and some other places of the coast, were found to contain them. The pearl fishery in this quarter was long a source of riches and revenue; but for the last century and a half it has been unproductive, few pearls in all that time having been found, and these few of little value. It is now abandoned to the Indians, who sell their pearls to the Dutch or English.

Climate.—The heat to which Caraccas is subject, notwithstanding its exposure to the influence of a tropical sun, is seldom excessive; the high elevation of a great part of its surface, and the fanning effects of the breeze which always blows from the sea, cool the atmosphere to a pleasant temperature. During winter, or rather the rainy season, which extends from May to November, the thermometer sometimes falls to 50°; and in summer, or the dry season, it is seldom seen to rise above 86°, except in some of the most exposed plains, in which the burning heat of the torrid zone is experienced in all its violence. The broad savannahs, through which the Oronooko and its tributary rivers have their course, are inundated during the whole period of the rainy season, and present to the observer one boundless expanse of troubled water. The rest of the year they are pastures clothed with flocks, or vallies covered over with corn.

Vegetation.—The fertile soil of this region, under the constant excitation of heat and moisture, sustains a vigorous and a various vegetation. Like the rest of America, vast tracts of the Caraccas are covered with thick forests, in which are cedar, oak, ebony, and many other sorts of trees of excellent timber, or useful for their medicinal or colorific qualities; coffee, cocoa, cotton, sugar, indigo, tobacco, wheat, maize, and a great variety of fruit-trees, are objects of culture. But the plantations of these valuable crops are under a bad system of management, and more than nine-tenths of the whole surface are left in a state of nature. The backwardness of the agriculture of this fine region is owing, according to Depons, to the number of mortgages with which almost every estate is burdened; the pious legacies with which they are encumbered; the pride of the planters, who disdain to superintend their own affairs; their ambition for public employments; the ignorance and the carelessness of the overseers to whom the charge of the plantations is committed; and the want of labourers, properly and seasonably to prepare the soil, to keep the growing crop clear of vermin and weeds, and to gather in the ripe produce. The use of the plough is unknown, but irrigation is well understood.

Animals.—The quadrupeds and birds of Caraccas are the same in general with those of the Brazils, and other parts of South America. The horses and horned cattle of Europe have become very numerous, and roam uncontrouled over the hills and the vallies of this highly favoured country.

Towns.—This captain-generalship is divided into five subordinate provinces; Maracaybo on the west, Cumana and the island of Margaretta on the east, Guiana on the south, and Venezuela in the centre; over which numerous towns, villages, and hamlets are scattered. Those towns which deserve to be particularly noticed are, St Jago de Leon, or Caraccas, the capital, which stands in 10° 31′ north latitude, eight leagues from the coast, in a beautiful valley 2000 feet above the level of the sea, on account of which it enjoys a perpetual spring. The streets are wide and straight; they intersect each other at right angles, which form the whole into divisions, called *quadras*. The principal square is used as the market place. The cathedral, the college, and the prison, occupy a part of three of its sides. The town contains 40,000 inhabitants.

Guayra,—the port town of Caraccas, is meanly built, at the foot of high mountains, close on the shore.

Maracaybo—is a tolerably built town, on the neck of the lake of the same name, by which it communicates with the interior. It stands 140 miles west from Caraccas, and contains 20,000 inhabitants.

Coro—was once the capital of Venezuela; it stands on a sandy soil, and has long been in a declining state. *St Philip* is well built, and has about 7000 inhabitants. It stands 50 leagues west from Caraccas. *Carora* has 6000 inhabitants. *Tucuyo*, which stands in a narrow valley, has also 6000 inhabitants. *Valencia*, built near the lake of the same name, has 8000 inhabitants. *Barquiscmento* stands in a fertile and beautiful district about 40 leagues south-west of Caraccas, and has 11,000 inhabitants. *La Vittoria* is a straggling town, interspersed with gardens; the officers of the militia of the vallies of Aragoa have their residence in this town. A Plaza is planned, but not completed; it however contains a church of superior architecture. In the vicinity the wheat and sugar cane are seen growing together. The inhabitants are 8000. *Guanara* stands on a river of the same name, 95 leagues from the capital, and contains 10,000 inhabitants. *San Carlos* has 9000. *Porto Cabello* about 8000. El Consejo, Calabosa, St Luis, Caraccas. St John the Baptist, Maracay, Truxillo, and a few other villages, have from four to six thousand inhabitants, of all colours.

Population.—The inhabitants of the whole captaincy are estimated at about 800,000, a fifth of whom are whites, three-tenths slaves, two-thirds free people of colour, and one-tenth Indians. The catholic faith prevails, but priests are on the decline, and no convent has been founded for the last eighty years. The military establishment in the provinces used to amount to 13,000 men. Some of the coast towns are well fortified; but the richest inland towns are left open. Indolence, gambling, and voluptuousness, debase the inhabitants of this region. Their cookery is Spanish; oil and garlic being ingredients in every dish. Poultry is scarce, so that a common fowl costs a dollar; but beef is cheap, and fish is abundant. Pocketing of fruit and sweetmeats is a common custom at the best tables. In a word, the manners are Spanish, by no means purified by being carried across the Atlantic, or mixed with the usages of the Indians.

Commerce.—The commerce of this rich country languished long under impolitic restrictions. The Dutch, after they settled in Curaçoa, first drew the attention of the Spanish colonists to the advantages of industry and trade, by the price which they paid for their commodities. A trifling traffic was soon after carried on with the mother country, and an extensive contraband trade with the more enterprizing Hollanders. In 1728 the merchants of Biscay offered to put an end to this illegal traffic, and to transport the produce of this colony to Spain. Their offer was accepted, and though they accomplished their design with moderation, yet their interference excited deep discontent in the province of Venezuela; for the removal of this dissatisfaction, an assembly, consisting of an equal number of merchants and planters, was established in the year 1750. Under this regulation, imperfect and restrained as it was, the country began to improve. The land was cultivated, towns were built, and riches increased. In 1778 the ports, both of Caraccas and Spain, were declared free, and a scale of duties, payable for the commodities exported, was at the same time established. The European merchandise in demand in Caraccas are linens, laces, and black stuffs both of woollen and silk, broad cloths, French hats, and coarse woollen, linen, and cotton manufactures.

The principal exports are cotton, coffee, cocoa, tobacco, indigo, and hides, all of which are of excellent quality, especially the cocoa, which is superior to that of the other colonies. The most frequented ports are Cumana, well sheltered from the inclemency of the weather; Guayra, little better than an open road, a strong surf breaks on the shore; Porto Cabello, large and safe; Coro, once the centre of the contraband trade; and Maracaybo, a capacious harbour, but rendered almost inaccessible by reason of a bar of sand which obstructs its entrance. Besides these there are many other bays and mouths of rivers which afford good moorings to the vessels employed in the trade of this country

Revenue.—A tax of *five per cent* is collected on all sales of every sort of property; two-ninths of the tithes go to the crown, which, with the duties on imports and exports, form the chief resources for defraying the public expences of the colony.

History.—This part of the continent of South America was discovered by Columbus in the year 1498, who took possession of it for the crown of Spain. Sometime afterward it was subdued by force of arms, and placed by Charles V. under the administration of a company of German merchants, by whom it was long harassed. The complaints which arose in consequence of this abuse of power led to the appointment of a government responsible to the crown for its conduct. The power of the governor of Caraccas, under the appellation of *Captain-general*, was supreme over all its subordinate provinces, both in civil and military affairs; and this system continued according to its original establishment till the year 1811, when the congress of Venezuela, refusing to submit to the usurped authority of Bonaparte, published a formal decree of their independence, and a declaration of their rights. A civil war has been the consequence, in which much blood has been shed; and the contest, it is feared, will cost a great deal more before it is finally decided. Humboldt's *Personal Narrative;* Depon's *Travels;* Semple's *Sketch of Caraccas.*

CARACCI, Ludovico, a celebrated Italian painter, and founder of the school which was distinguished by the name of Caracci's academy, was born at Bologna in the year 1555, and died in 1619. He carefully studied the works of Titian, Paul Veronese, and Corregio; and thus, improving his taste, rose to the first eminence in his profession. Grace, dignity, and sweetness are the characteristic features of his works; and even when he aspired at elegance the efforts of his pencil were successful. He was extremely assiduous, and peculiarly fortunate in directing the studies of the pupils who attended the academy which he established and superintended. His most celebrated painting in oil is the altar-piece of St John the Baptist in the Cortosa of Bologna; a picture which graced the walls of the Louvre among the other plunder of the valuable productions of the Italian school, but is now undoubtedly restored to its rightful possessors.

CARACCI, Augustine, an eminent Italian artist, was cousin-german of Louis Caracci, and was born at Bologna in 1558, and died in 1602. He was chiefly instructed in the principles and practice of painting by his cousin, whom he assisted in the management of the academy. His style of execution is distinguished by correctness and elegance of form, refined taste, and vigorous expression. His most admired painting in oil is the Communion of St Jerome, in Bologna, which shared the fate of the other rich spoils of Italy, being carried off to adorn the French Louvre, but it is hoped has been restored to its own place.

CARACCI, Annibale, a celebrated Italian painter, was the brother of the preceding artist, and was born at Bologna in 1560, and died in 1609. To his cousin Louis he was indebted for his knowledge of the principles of the art. He rose to great eminence in his profession; the efforts of his genius were not confined to one department, for he painted portraits and history, but excelled chiefly in landscapes. His works are distinguished by grandeur of design, liveliness of expression, vigour and firmness of execution. His most splendid undertaking is the Farnese Gallery at Rome, which he was invited to execute by the cardinal of that name, and which required the assiduous labour of ten years; and for which, it ought to be recorded, he received only the scanty remuneration of five hundred crowns.

CARAMANIA, a province of Asiatic Turkey, which extends along that part of the Mediterranean which is opposite to the island of Cyprus, and includes some regions, as Pamphylia, Cilicia, Lycaonia, and others, which were famous in antiquity. The coast is in general lofty; but presents many excellent and capacious harbours. The mountains are covered with thick forests; several lakes are well supplied with fish, and furnish abundance of salt; and a good deal of silk is produced. Satalia, which stands on a gulf of the same name, is the capital of the province.

CARAVAN, derived from a Persian word which signifies a trader or merchant, is a company of merchants or pilgrims who travel through Africa and Arabia, in large bodies, to secure themselves against the attacks of the native tribes, who live chiefly by plunder. By means of these caravans a great trade is carried on in the central parts of Africa. Their departure is fixed at stated periods, and four of them proceed annually to Mecca; the first is from Damascus, and consists of the pilgrims and merchants from Europe and Asia; the second, composed of the Mahometans of Barbary, departs from Cairo; the third assembles near the entrance to the Red sea; and the fourth, which is made up of Persians, sets out from Babylon.

CARAVANSERA, a public building in eastern countries, for the accommodation of the merchants and pilgrims who accompany the caravans. Edifices of this description are of a square form, often of great magnitude, and have one or two stories above the ground-floor. A spacious court occupies the middle of the building, and is surrounded with magazines and piazzas for the reception of merchandise and the camels which carry it; the upper apartments are destined to the accommodation of the merchants and travellers. Some of these caravanseras, which are erected in the towns, are magnificent structures; and some of them are built in desert places, which afford no other kind of accommodation. But in such places the traveller finds nothing but the bare walls; he must carry with him everything else for his own use.

CARBONE, in chemical language, is the element or pure part of charcoal, of which the diamond, which is crystallized carbone, furnishes the best example. See CHEMISTRY.

CARBONATE, a compound of carbonic acid and some base, as with lime, which forms common limestone, or chalk, or marble; or with the oxide of copper, which forms blue or green copper-ore. See CHEMISTRY.

CARBONIC ACID, a compound of carbone and oxygen, which was formerly known by the name of fixed air, or aerial acid; and of which the air, which escapes from brisk small beer, and the air which collects at the bottom of deep pits or wells, and is so noxious to animal life, are examples. See CHEMISTRY.

CARBURET, a compound of carbone with some other substance. Common cast-iron, which is composed of carbone and iron, is a carburet of iron; and the air which is consumed in the well-known gas-lights, is a compound of carbone and hydrogen, and is called carburetted hydrogen. See CHEMISTRY.

CARCASS, a hollow body which contains combustible matters, and is thrown from a mortar for the purpose of annoying the enemy, by setting fire to houses. The carcass is sometimes an iron shell, with a number of openings; and sometimes it is made of ribs of iron covered with pitched cloth. Implements of war of this description, it is said, were first brought into use by the bishop of Munster, and were employed in 1672 at the siege of Croll.

CARCASSONE, the capital of the department of the Aude in France; stands on the banks of the river Aude, which divides the town into the upper and lower town, and partly on the banks of the canal of Languedoc; is surrounded by a wall, and defended by a castle on an elevated spot, which is also occupied by the cathedral. The lower town is of a square form; has regular streets; and a spacious square is adorned with a fountain. The population is about 15,000; and the inhabitants, who are chiefly employed in the manufacture of woollen stuffs, are distinguished for their industry.

CARD-MAKING.

CARDS are well known instruments employed in the preliminary operations which wool and cotton require for being manufactured into cloth. In the extensive manufactures of Great Britain, card-making has become an object of great importance; and in no department of useful art has ingenuity been more successfully exercised, in facilitating and abridging the numerous minute operations which it requires.

The manufacture of cards in Britain probably commenced about the middle of the 15th century. Before that time they were imported from the Netherlands, along with the Flemish weavers, who emigrated to Britain, and greatly improved the woollen manufactures. But in 1463, for the purpose of encouraging the manufacture at home, the importation of cards, and other instruments and utensils of iron, steel, and copper was prohibited.

The first kind of cards, which continued long in use, were called *hand-cards*, because the operation was performed by the hand with a pair of cards. In the progressive improvement of manufactures, and

Cardmaking the introduction of machinery, stock-cards were employed in place of hand-cards, which were farther superseded by the extensive use of cylindrical cards.

The principal card-manufactories in Britain are at Halifax and neighbourhood, in Yorkshire, and at Leith. The oldest establishments of the kind in this country are in Yorkshire; but the first and oldest card-manufactory in Scotland is still continued, at Leith, by Messrs Stead and Paterson; and although it is the most extensive and best conducted manufacture in the northern part of the kingdom, yet it has been passed unnoticed in topographical accounts, and in treatises which are professedly descriptive of card-making. The great-grandfather of Mr Stead, one of the present proprietors, was invited from Yorkshire to Scotland in 1696, and settled at Haddington, for the purpose of manufacturing cards for a woollen manufactory which was established at that place. The establishment, which has now existed in eight generations of the same family, was afterwards removed to its present situation in the vicinity of Leith; and through the liberality of the proprietors we were gratified with a minute inspection of the whole operations connected with the manufacture, and had an opportunity of comparing the instruments which were in use for the different operations 120 years ago, with the elegant and more perfect apparatus which is now employed for the same purposes. This comparison affords a fine example of the resources of art, and of their application to facilitate and accelerate labour. In this manufactory, every part of the work, from the preparation of the wire from the iron bar, to the completion of the card, is performed, and the greater part of the operations is conducted by machinery set in motion by an excellent steam-engine.

In the preparation of the wire for cards, three different operations are required; cutting to proper length; doubling, to give it the form of a staple, as it is called; and, lastly, giving it the knee-bend. To these operations may be added the preparation and pricking of the leather, the insertion of the wires, and the setting and polishing to make them uniform and smooth.

Cutting.—The wires are cut off from a coil consisting of 30 or 40 turns, the separated ends of which are placed in a steel-gauge, which marks the proper length of the teeth. The cutting instrument is a pair of strong shears fixed to the edge of the table at which the work is done, and moved by the pressure of the foot on a lever under the table. When the pressure is removed, the shears open by a spring or counterbalancing weight operating over a pulley. In this way, the number of wires cut at each stroke corresponds with the number of turns in the coil, and this number is greater or smaller according to the size of the wire. When the wires are small, from 30 to 235 are cut off at each stroke of the shears.

Doubling.—The operation of bending the wire into the form of a staple, is called doubling, and this is performed by means of an instrument called the *doubler*, which consists of a steel gauge fixed in the end of a wooden handle. The ends of the wires are placed in a groove, the depth of which is exactly equal to the intended length of one of the legs of the staple. The wires are then bent by the pressure of Cardmaking an instrument called the *bender*, which is somewhat in the form of a small reaping-hook without an edge, over a small flat bar of steel fixed in the doubler, and called the *bridge*; and, by a second pressure, bends the wire over the opposite angle of the bridge, and in this way the second leg of the staple is formed, and of the same length as the first. From 30 to 150 of these staples are made at a single operation when the wire is small; but for thicker wire a more powerful apparatus is required. The doubler is then fixed in a frame, and the bender operates by means of a strong lever. With a small steel knife, the wires are removed from the bridge of the doubler, and are conveyed to a machine by which the operation of bending is performed.

Bending.—The knee-bend which is given to the staples, is executed by a very ingenious machine, said to have been the invention of a quaker about the year 1775. This machine operates by means of wheels like clock-work, and the moving power is a weight which acts over a set of pullies, like the common roasting-jack. The machine is about eight inches long, and an axis, extending its whole length, revolves equally by the action of the apparatus now mentioned. Eight or ten small levers or claws are screwed on the axis at certain distances; the height of these claws or levers, which may be increased or diminished by the screw, is proportioned to the bend of the staple required. Opposite to each lever, and placed at some height above the axis, is a double brass ruler, on which is suspended a number of staples as they are removed from the bridge of the doubler with the knife. This ruler is slightly inclined, and during each revolution of the axis, a single staple is lifted over a knob or projection by means of a small tooth or lever called the *kicker*, which is concealed in the groove of the ruler. The staple runs down another inclined ruler, at the bottom of which is a recess which admits the legs of the staple. In this position, the claw or lever, by the revolution of the axis gives the knee bend to the legs of the staple. After the claw has passed, the staple instantly springs out of the recess by the reaction of the wire, while another staple is brought down to undergo the same operation at next revolution. The number of staples bent at each revolution of the axis in this machine, is equal to the number of levers with which it is furnished; and the advantages of such an apparatus must be obvious, for, from the accuracy of its construction and operation, the whole of the staples are bent at precisely the same angle.

In the early period of the card manufacture, this operation was performed with a very simple machine. It is a small axis, on the circumference of which is inserted a plate of steel, in which two small holes are drilled to receive the legs of the staple. A single staple is inserted by the hand at each revolution of the axis, which is turned by a wench or handle with the other hand. In the revolution of the axis, the staple is brought into contact with a strong spring, in passing which it receives the bend. But as the strength of the spring cannot be uniformly the same, the uniformity of the knee bend cannot always be depended on. A machine which operates on a similar principle is still in use, to give the knee bend to strong wire; a single staple is bent at a time; the machine is set in motion by the pressure of the foot on a lever; and while the staple is inserted with one hand, it is removed from its place after being bent by means of a lever, which is acted on by the other. This work is generally performed by women.

But ingenuity has been exerted in the invention of machines which perform all the different operations of cutting, doubling, and bending successively. A machine of this description is employed at a card manufactory in Yorkshire; and the model of another on a construction somewhat similar, and the invention of Mr Beard in the county of Essex, was presented in 1805 to the Society for the Encouragement of Arts and Manufactures; and a premium of forty guineas, with a silver medal, was awarded to the inventor for his valuable improvements.

Pricking the leather.—The holes in the leather, in which the staples are inserted, were formerly made by a manual operation with a double awl; lines were first drawn parallel to each other, by means of teeth at equal distances, and drawn at right angles to one side of the piece of leather to be pierced. The lines thus drawn regulated the perforations in one direction, and the distance between them in another direction was regulated by the eye, and the movement of the hand of the workman; but this operation is now performed with more accuracy and rapidity, by means of machinery. The leather to be pierced is stretched tight in the machine, and as it passes over a brass bar it is perforated by a double row of prickers, placed transversely in another brass bar, which is strongly secured by screws in a frame which moves vertically by a lever; the lower brass bar has also two rows of perforations, which correspond exactly with the steel points or prickers fixed in the upper bar. By the pressure of the lever, which is wrought by the right hand of the workman, a double row of perforations is made. That part of the machine, or the carriage in which the leather is stretched, moves horizontally by the action of a weight which operates by means of a cord passing over a pulley. The teeth of a rack attached to one side of the carriage, work in an endless screw, which is fixed on the end of a long axis placed parallel to the direction of the carriage. On the other end of this axis a cylindrical brass wheel is fixed, and on the circumference of this wheel circles are traced, each of which is equally divided, but with a different number of divisions. A spring is so fitted that it applies to the divisions, and a projection or tooth at the end of the spring enters the small holes in the circles, and thus prevents the revolution of the axis which would take place by the effect of the weight and the action of the rack-work of the carriage on the endless screw. While the tooth of the spring is in one of the holes of the circle, the machine is at rest, and the workman presses down the lever, and forms a number of perforations in the leather corresponding to the steel-points in the upper brass bar. The lever is then lifted up, and the workman, with his left hand, raises the spring, which allows the axis to move till the tooth enters the next hole in the circle by the elasticity of the spring; and the carriage being again at rest, another double row of perforations is made in the leather. In different kinds of cards the teeth are set at different distances; and for this purpose the distance between the different rows of perforations must be accommodated. This is easily accomplished by the simple contrivance of perforating the circles on the cylindrical wheel with a greater or less number; thus, if 12 holes are made in the circumference of one circle, and only six in that of another, while the spring acts on the first, 12 double-rows of perforations will be made in the leather, and while it acts on the second, six rows only will be made on the same space.

The leather being pierced, and the staples doubled and bent in the manner already described, they are inserted by the hand, and, after they are inserted, they are carefully examined by an experienced workman, to see that all the teeth are regularly set. The finer kinds of cards, which are used in the preliminary process of cotton-spinning, undergo another operation. To remove any roughness or inequality of the teeth they are fixed on an iron cylinder, and while it is turned round by one person, another applies a bar of wood, on which is spread a quantity of emery to give them a smooth polish.

Cards are distinguished by different names, according to their form or the mode in which they are wrought; thus *hand-cards* are nearly of a square form, and are nailed on pieces of wood to which handles are attached, and have their name from being wrought by the hand; *sheet-cards* are of a large size, to cover cylinders which are moved by machinery; and *fillet-cards* are made on narrow pieces of leather, which are fixed spirally on cylinders moved in the same way.

Pointed teethed cards.—A very essential improvement has been made in the construction of cards, by Mr Stead, of the card manufactory, Leith. Like every other valuable improvement, it is remarkable for its simplicity; and to the kindness and liberality of that gentleman we are indebted for permission to extract his own account of the invention, from a copy with which he favoured us of the specification of his patent, which extends over Great Britain and Ireland. According to his description, instead of the ordinary form of cards now in use, the teeth of this card are tapered gradually from what is called the knee, or from the leather or material in which they are set, and terminate in a sharp point in the form of a heckle. By this means the cards can be filled with wire of a much stronger and coarser size than they could be without this method of pointing, and they can also be filled closer in the wire, so as to combine the advantage of a fine card with the strength of a coarser one, without injury to the materials carded. The teeth of this card are made with either a kneed or circular hook; the latter is preferable, especially in the carding of flax, tow, and silk, as the card is more easily relieved and cleared of the stuff. Another improvement from this method of making cards is, that the teeth, owing to their form, may be grinded or sharpened repeatedly, until worn down, without loosing essentially the benefit of the original point.

The operations of pointing and polishing the points are executed by women, and the grinding and polish-

Cardmaking ing apparatus is fixed on a long axis, which is driven by machinery. The point is formed by grinding on a small grind-stone. The wires are then passed to another person to smooth and polish them; and, to save time and abridge labour, a considerable number is done at one operation by gently twirling them between the finger and thumb while they are pressed on the polishing apparatus, and thus every part of the circumference of the tooth is brought in contact with the polishing machine. Although the teeth were originally cut precisely of the same length, their extremities are apt to be worn down unequally during these operations; and thus it becomes necessary to arrange and sort the whole, that teeth of the same length may be employed in the same cards. This is done by means of a gauge similar to what is used in the original cutting of the wires. The other operations of doubling and bending are performed in the usual way. The manufacture of this excellent description of cards is now successfully conducted by Messrs Stead and Paterson, under the privilege of the patent already alluded to.

Improved machinery.—The machinery for abridging the labour of card-making has been still farther improved. Mr Fryer of Rastrick, near Huddersfield in Yorkshire, has invented an apparatus, by which the leather is pierced, and the wires previously doubled are inserted, and, after insertion, receive the knee-bend. But the most complete machine for card-making is the invention of Mr Amos Whittamore, an American. From the date of his invention in 1797, he obtained a patent for the exclusive privilege of using these machines for 14 years; and, from an account drawn up in 1809, by William Whittamore of West Cambridge, in the state of Massachusets, and one of the proprietors of the works, it appears that he had, in conjunction with the patentee, erected 55 of those machines, of which 37 were at that time in use. The amount of capital required for the concern is stated at 40,000 or 50,000 dollars; 40 persons are employed in the manufactory, and the weekly produce of their labours amounts to 180 dozen pairs of hand-cards, and 200 square-feet of cards for the woollen and cotton manufactures. It appears from the report, that the wire manufactured in America is greatly inferior to English wire for card-making, and this inferiority in the quality of the wire is ascribed to the want of capital, and of encouragement to the manufacture.

This ingenious machinery has been introduced into England under the privilege of a British patent, granted to the American patentee, in conjunction with Mr Joseph Dyer of Manchester. Mr Dyer, it is understood, has brought the apparatus by his own improvements to a high degree of perfection; and if a favourable opinion can be formed from the beauty of the manufacture, which, in the regularity and uniformity of the teeth of the cards, is far superior to what are made in any other way, these machines, when the period of the exclusive privilege has expired, must undoubtedly take the place of all others that have been hitherto invented.

In the apparatus now alluded to, the whole operations of cutting the wires, doubling them, piercing the leather, inserting the staples, and forming the knee-bend, which is done after insertion, are performed by machinery. A single wire only is completed at a time; but the rapidity of the action is so great, that four wires can be prepared and inserted in a second; and from this account it appears, that the whole operations are completed sooner by the improved machinery, than any individual operation in the usual way.

Cards. CARDS are oblong pieces of fine pasteboard, which are employed in various well known games for amusement. Cards are supposed to have been invented about the year 1390, for the amusement of Charles VI. of France, who had fallen into a state of melancholy. The four suits or colours are meant to represent the four classes of men in the kingdom. The hearts allude to the choirmen or ecclesiastics. The nobility or military part of the nation is represented by the points of lances or pikes, which are called in English *spades*, perhaps from the Spanish word *espadas*, signifying swords. Citizens, merchants, or tradesmen, are designed by diamonds or square stones, tyles, or the like; and the trefoil leaf which has been corrupted into clubs, alludes to husbandmen and peasants. The English names, it may be observed seem to have been borrowed from the Spaniards.

The four kings are David, Alexander, Cæsar, and Charles, in allusion to the celebrated monarchies of the Jews, Greeks, Romans, and Franks under Charlemagne. Argine, the anagram of *Regina* queen, Esther, Judith, and Pallas, expressive of birth, piety, fortitude, and wisdom, are alluded to by the queens. These names were on the French cards. The knaves, according to the original meaning of the word, were intended to represent the servants or attendants of knights. See GAMES.

CARDAMINE, CUCKOO-FLOWER, a genus of plants belonging to the Tetradynamia class, and of which several species are natives of Britain.

Cardan. CARDAN, a celebrated mathematician and medical writer, was born at Pavia in Italy in 1501, was the illegitimate offspring of an advocate at Milan, and was instructed by his father in mathematics, astronomy, and judicial astrology, in which latter he seems to have been a firm believer and an expert practitioner. In his 22d year, he gave lessons on mathematics at Pavia; ten years afterwards, he was appointed to the professorship of the same science at Milan; and at the same time he commenced medical practice, from which, or from his writings, he acquired a high reputation; for in 1552, he was called to visit the archbishop of St Andrews in Scotland, and had the good fortune to cure the primate of an asthmatic disorder; and in some part of his works, he notices some of the objects, connected with natural history, which he observed in the king's park at Edinburgh, during his visit to Scotland at that time.

On his return to Milan, after nearly a year's absence, he resumed his former occupations, both of a public and private nature, and continued till the year 1559, when he accepted the professorship of medicine at Pavia. In the succeeding year he was appointed to the same chair at Bologna, in which situation he continued for 10 years. But for some public offence, the nature of which is not stated, he was thrown into prison, and at the end of some months, having regained his liberty, he retired to Rome, and received a pension from the pope, which was continued till his death in 1575.

The life of this singular man seems to have been strongly marked with restlessness and caprice, while it displayed powerful talents and great industry. It is said that he was greatly addicted to gambling, and in this pursuit squandered his property. In mathematical investigations, and particularly in the manner which he treated the subject of cubic equations, he holds a respectable rank, although it is alleged that he was indebted to others for some hints on the subject. But considering the period in which he lived, and the prevailing studies of the times, he cannot be fairly charged with being altogether devoid of reason or intelligence when he wrote on judicial astrology, a subject which had occupied the attention of the most learned men of his age. He was peculiarly unfortunate in his family; his sons were of the most abandoned characters; and one of them forfeited his life to the laws of his country for destroying his wife by poison. The works of Cardan, which are extremely various and numerous on the subjects already alluded to, were published at Lyons in 1663, in 10 vols. *folio*.

CARDIAC, derived from the Greek word which signifies the *heart*, denotes, in a medical sense, something which is beneficial to that organ; and *cardiacs*, in a more enlarged acceptation, are synonymous with cordials which promote and invigorate the powers of digestion.

CARDIALGIA, a sensation of heat and acrimony at the upper orifice or entrance into the stomach, and denominated in English *cardiac passion* or *heart-burn*. See MEDICINE.

CARDIFF, the county town of Glamorganshire in South Wales. See GLAMORGANSHIRE.

CARDIGANSHIRE, a county of South Wales, which is bounded on the north by Merionethshire, on the west by Cardigan bay, on the south by Caermarthen and Pembroke, and on the east by Radnor and Brecknock; and is about 40 miles in length, 20 in breadth, and 100 in circumference. The western side has suffered by the encroachments of the sea, and where flourishing towns are supposed to have formerly existed, a few villages now remain. The county may be divided into two districts, the lower and the upper. Of the elevated grounds of the lower district, the soil is generally a light sandy loam, from four inches to a foot in depth, but the soil of the vallies is deep. Good crops of wheat, barley, peas, oats, turnips, and potatoes, are raised. Cows are extensively reared by the farmers, but the number of sheep is declining. Cheese is manufactured, partly for exportation and partly for domestic use. The upper district is mountainous, and the soil of the vallies is of a stiff clay, with a mixture of light loam. The rearing of cattle and horses is the main dependence here, together with sheep and pigs. The waste lands in Cardiganshire are very extensive, probably from a want of industry in their cultivation; but improvements have been proposed, and are going on promisingly. The climate is mild and favourable, and snow seldom lies long.

The principal rivers are the Tivy, the Rydol, and the Ystwith. The Tivy rises from one of the small lakes to the eastward, and, pursuing an irregular course, falls into the Irish sea about two miles below Cardigan. The Rydol rises on the south-west side of Plynlimmon, and discharges itself into the Irish sea near Aberystwith; and the Ystwith rises among the hills in the eastern district; and springs are very general on the hills and vallies, some of which, after heavy rain, become impetuous torrents.

Lead and some other minerals which are found in the mountains in the north of the county, were formerly wrought to advantage, but they are now neglected. Rich veins of copper have likewise been discovered, which cannot be wrought owing to the great want of fuel.

The population of Cardiganshire was stated, in 1801, at 42,956, and had increased in 1811 to 50,260. The principal manufactures are the iron and tin works. A good deal of wool is spun, and the fishing in the bay of Cardigan occupies a number of the inhabitants. The chief exports are iron, tin, black cattle, pigs, salt butter, barley, and oats. Several fairs are held, where much business is transacted in the commodities of the place. This county contains several market towns, of which Aberystwith and Cardigan are the chief.

Cardigan, the county town, stands on a steep bank, about two miles from the mouth of the river Tivy, which is navigable for vessels of more than 100 tons burthen. Cardigan had at one time a considerable commercial intercourse with Ireland, but its chief trade is in iron, the produce of the works in the neighbourhood. The population exceeds 2000. See ABERYSTWITH.

CARDINAL, derived from the Latin word which signifies *a hinge*, is an appellation expressive of superiority or pre-eminence, as the cardinal virtues, justice, prudence, temperance, and fortitude, which are supposed to be the foundation of all the rest; the cardinal points, or chief regions of the heavens, which are north and south, east and west; and the cardinal winds, which blow from these points.

CARDINAL, a dignitary of the church of Rome, next in rank to the pope himself. Of the origin of cardinals no distinct account is recorded, but they now compose the council or senate of the pope, and form the conclave for the election of the head of the church; and for the regulation of their rights and titles, a constitution drawn up by Pope John is preserved in the Vatican.

In the first institution of cardinals they were only the principal priests, or incumbents of the parishes of the city of Rome; in the primitive church, the chief priest of a parish, next in rank to the bishop, was called *presbyter cardinalis*, to distinguish him from the inferior priests who possessed no benefice. The duty of baptising and administering the eucharist, was committed to these cardinal priests alone, and when they were created bishops they were considered as being raised to a higher dignity, and having vacated their benefice. Three kinds of churches were originally established. To the first, parishes were attached; the second were called deaconries, which were chapels belonging to hospitals, and served by deacons; and the third were oratories, in which private masses were said, and the other duties of which were discharged by local or resident chaplains. The principal, or parish church, was denominated cardinal, to distinguish it from the others, and the officiating minister was called *cardinal priest*. Some chapels also conferred the title of *cardinal deacon*. It was not till about the 11th century that cardinals obtained a higher rank than bishops, and, according to the constitution already alluded to, the pope is supposed to represent Moses, and the cardinals the 70 elders of Israel. But it appears that this institution, deriving its origin from small beginnings, has varied greatly in the number of its members. The cardinal deacons were at first only seven, and were afterwards increased to fourteen. The number of cardinal priests was 50, and, with the six cardinal bishops, made up the whole number of 70. The number was reduced by the council of Constance to 24, but Pope Sextus IV. raised it to 65.

When cardinals are created, they receivered caps, as a badge of the rank to which they are promoted, from the hands of the pope himself, but if they are at a distance, the cap is transmitted by some person of rank: they wear a prescribed dress, which consists of a rochet, over which is a short purple mantle, and their garments are either red or violet. Cardinals were formerly addressed *most illustrious*; but by a decree of Urban VIII. in 1630, this title was changed into *eminence*. All matters, whether of a political or ecclesiastical nature, connected with the see of Rome, are submitted to the cognizance of the cardinals, and they not only claim the power of electing the pope, but assert the privilege of choosing one of their own body.

CARDIUM, or Cockle, a genus of shell-fish, belonging to the order of Bivalves, of which one species *cardium edule*, or common cockle, is found in immense numbers on many of the sandy shores of Britain, and is much employed as food by the inhabitants.

CARDONA, a town of Catalonia in Spain. See Catalonia.

CARDUUS, the Thistle, a genus of plants belonging to the Syngenesia class.

CAREENING, in maritime affairs, denotes the operation of making a ship incline to one side, for the purpose of caulking or repairing those parts of the bottom which are usually under water. This is done by the weight of the ballast, which is placed on one side, or in ships of war, by means of the guns.

CARELIA, the eastern province of Finland, is divided into Swedish Carelia and Muscovite Carelia.

CARELSCRONA, or Carlscrona, a sea-port town of the province of Blekingham in Sweden; was founded in 1680 by Charles XI. from whom it derives its name, as a naval station. The chief part of the town stands on a rocky island, between which and the main land a communication is formed by means of two wooden bridges. The houses are mostly of wood; and the public buildings, as the town-house, the arsenal, and some of the churches, are elegant structures. The harbour is spacious and commodious, and with depth of water for the largest ships. It is capable of receiving more than 100 vessels, while it is strongly protected both by nature and art. Large docks, fit for receiving first rate ships of war, have been dug out of the solid rock, and constructed at an immense expense. The population is about 13,000 or 14,000; and the inhabitants are chiefly employed in ship-building, or in those arts which are immediately connected with it, beside some trade in deals, pitch, tar, and other productions of the surrounding territory. The governor of the province has his residence in this place; and it is one of the four towns in Sweden in which the Jews are permitted to erect synagogues.

CAREX, Sedge Grass, a genus of plants belonging to the Monœcia class.

CAREY, Harry, an English poet, who flourished in the early part of the 18th century, was the author of various songs which were sung in modern comedies, as those in the *Provoked Husband*, and of several dramatic pieces, intended as satires on some of the modern tragedies and the Italian opera. Such are his *Chrononhotonthologos*, and the *Dragon of Wantley*, the first of which still appears occasionally on the stage, A collection of all his songs, entitled the *Musical Century*, was published in 1740. He was also distinguished by his musical genius; and some of the airs to which his songs were sung were of his own composition. But, like many poets, prudence and economy were not always his steady guides; his income and expenditure, it would appear, were altogether disproportionate; and he often laboured under great pecuniary embarrassments, which led him, in 1744, in a fit of despair, to the commission of suicide.

CARIA, an ancient kingdom of Asia Minor, which is supposed to have had the Mediterranean sea for its boundary on the south, the Ægean sea on the west, Ionia on the north, and Phrygia on the east, and seems to have held a conspicuous station in the early history of the world. Caria became afterwards subject to the Persians; and the Carian fleet, which had joined Xerxes against the Greeks, was the last which retired from the decisive victory of Salamis. The Carians afterward maintained many severe struggles with the Greeks; and in a later period of the history of this country, it has shared the fate of Asia Minor.

CARIBBEE ISLANDS, a cluster of islands in the Atlantic ocean, which are included between the 11° and 19° of N. Lat. and are arranged in a semicircular form. See America.

CARICA, the Papaw, a genus of plants belonging to the Diœcia class. See Botany.

CARILLONS are musical instruments, composed of a series of bells accurately tuned to the tones and half tones of the scale, and furnished with keys, like those of the harpsichord or organ, which the player, or *carilloneur*, strikes with his hands; and those connected with the large bells have pedals, on which he acts with his feet. A series of bells of this description is common in the steeples of the churches in Holland and the Netherlands, and is not unknown in the northern parts of Britain, as in Edinburgh, Glasgow, and Stirling.

CARINI, a town of Sicily, with a population of 5 or 6,000, stands in a fertile valley, which is well cultivated, and produces all kinds of grain and fruits.

CARINTHIA, a duchy of the circle of Austria in Germany, bounded on the east and north by Styria, on the west by Tyrol, and on the south by the Venetian territories and Carniola. It is about 118 miles in length, and 50 in breadth, and is surrounded by walls and a ditch. The country is mountainous and woody, and the vallies are fruitful, producing grain of different kinds, though not in sufficient abundance for the consumpt; and some flax is also raised. Cyder, and two kinds of ale are common; and turpentine is successfully procured here. Great numbers of cattle and horses are maintained on the pastures. Swine are abundant; and in the forests are found wild goats and bears. The climate is not unfavourable, though coldish. Lakes are not unfrequent; the largest is the Wordtsee, eight miles long; and the chief river is the Drave, which traverses the country from west to east, and which, with the Gail, the Moll, the Lyser, the Glan, the Gurk, and the Lavant, abounds in fish.

Carinthia is very productive of minerals, as iron, copper, lead, of which there are several mines, calamine, bismuth, granite, marble, alabaster, nitre and bolar earth.

The population in 1810 was 300,000; and the industry of the inhabitants is chiefly occupied in manufacturing the produce of the mines, which is the main source of wealth, together with the preparing of goats and chamois skins. The exports are iron, steel, lead, copper, calamine, flax, linen, hides, and vast numbers of cattle, which are sent to Venice. Among the imports are wines, spirituous liquors, sugar, cotton, coffee, drugs, corn, cloth, and salt.

Carinthia is divided into the lower and the upper. The principal towns of the former are Klagenfurth, which is considered the capital, St Veit, Friesach, Volken, St Andrée, Wolfsberg, and Gurk; and those of the upper are Villach and Gmund.

CARLINA, the Carline Thistle, a genus of plants belonging to the Syngenesia class.

CARLINGFORD, a sea-port town of the county of Lowth in Ireland, and about 22 miles north from Drogheda.

CARLISLE, a city of Cumberland in England. See Cumberland.

CARLOW, an inland county in the province of Leinster, in Ireland, is bounded on the north and west by Kildare, Queen's-county, and Kilkenny, and on the south and east by Wicklow and Wexford, is chiefly included between the two principal rivers the Barrow and the Slaney, and is about 33 miles in length from north to south, and nearly 30 miles at its greatest breadth. That part of the county to the westward of the river Barrow is mountainous and rugged; and another lofty ridge, equally bleak and barren, stretches along the south-eastern quarter; but in the flat part of the county, and the less elevated districts, the soil is fertile and well cultivated. Granite is the prevailing rock in some of the high mountains; limestone is abundant in some places; some marble is met with; and the ores of iron were at one time wrought, and furnished materials to a considerable foundery which existed in the time of Charles I. The river Slaney traverses part of the county on the east, and the Barrow is navigable to the town of Carlow, from which it communicates with the Dublin canal.

Carlow is divided into five baronies and 50 parishes. The population is stated at 44,000; and the proportion of the Catholic and Protestant inhabitants is said to be 10 of the former to one of the latter. Tillage husbandry is not prosecuted on a large scale in this county; but a great deal of barley, of a superior quality is raised, and sent to different parts of Ireland. The dairy husbandry is an object of great attention, and the produce in butter bears a high character both in the London and Dublin markets. The principal towns of Carlow are, Carlow, the county town, Tullow, Leighlinbridge, Rutland, Palatine-town, Hacketstown, and Gousbridge.

Carlow, the county town, stands on the east side of the river Barrow, is pretty regularly built, was formerly surrounded with walls, and defended by a castle; contains about 7000 inhabitants, including the village of Grange, which is in Queen's-county, and connected by a bridge, and has some manufactures of coarse woollen cloths, and hardware, as shears, scythes, and reaping-hooks. Among the public buildings is a seminary for the education of Roman Catholic priests; and the ruins of a fine abbey are still visible.

Leighlinbridge is also situated on the Barrow, is seven miles south from Carlow, and is chiefly remarkable for a very large corn-mill.

CARLSBAD, a town of Bohemia, stands on the river Eger, is famous for its hot springs, and celebrated for its manufactures of tin and steel, and particularly for the fabrication of arms. The population is stated at 3000, which sometimes, during the bathing season in June and July, receives an accession of strangers equal to that number. The temperature of the different springs varies from 120° to 165° of Fahrenheit; and the saline ingredients which enter into their composition are, Glauber salt, common salt, carbonate of soda, and a portion of lime.

CARLSCRONA, a sea-port town of Sweden. See Carelscrona.

CARLSRUHE, a town in the circle of Swabia, and marquisate of Baden, in Germany, was founded about the commencement of the 18th century, and is built on a regular plan. The streets are uniformly arranged, and the houses are of the same size and height. The palace, some of the churches, and houses for public institutions, are elegant structures. The population is about 10,000. Some manufactures have been introduced, particularly watch-making and works in steel.

CARLSTADT, a town of West Gothland in Sweden. See Gothland.

CARMAGNOLA, a town in the marquisate of Saluzzo in Italy, is situated near the river Po, is strongly fortified, and, including the suburbs, contains 12,000 inhabitants. The surrounding territory is fertile, and produces abundance of grain, flax, and silk.

CARMEL, a lofty mountain of Palestine, which forms a remarkable promontory on the shore of the Mediterranean, by which it is bounded on the west, has the bay of Acre on the north, and the plain of Sharon on the south; is said to be about 2000 feet in height; is celebrated in Scripture on account of its fertility; and, even in the present day, the wild vine and the olive are seen rising among the brambles and native plants; but its sides are steep and rugged, and in many places the naked rock presents itself. Other places which were remarkable for their fertility, were distinguished by a similar appellation. This mountain is known in Scripture as the abode of Elijah and Elisha; and from this circumstance it has been since held in great veneration by Jews, Christians, and even Mahometans.

A monastic institution, deriving its name from the mountain, and called the order of Carmelites, was very early established; and a convent of the same order still remains. The ancient monastery is in ruins, and a Mahometan mosque has been erected.

CARNATIC, a country of Hindostan, which lies on the east side of the Indian peninsula. See HINDOSTAN.

CARNEADES, a celebrated Greek philosopher, and founder of the third academy, was a native of Cyrene in Africa; and one of the grand principles of his philosophy was, that there are only probabilities or resemblances of truth in the mind of man, so that, of two things directly opposite, either may be chosen indifferently. He died in the fourth year of the 162d Olympiad, and when he had reached nearly the 90th year of his age.

CARNELIAN, a species of mineral belonging to the siliceous genus, which derives its name from its reddish flesh colour, but is sometimes yellowish and whitish. See GEOLOGY.

CARNICOBAR, one of the cluster of islands in the bay of Bengal, called Nicobar. See NICOBAR.

CARNIOLA, a duchy of the circle of Austria in Germany, is bounded on the east and south by Dalmatia and Croatia, and the Adriatic sea, and part of Istria, and on the west and north by the same sea, and Friuli, and Carinthia, and Styria, is about 120 miles in length, 100 miles at its greatest breadth, and exhibits in general a mountainous aspect. Some of the mountains are always covered with snow, and one of them rises more than 10,000 feet above the level of the sea. But numerous fertile vallies and rich fields present a fine contrast to the elevated and less productive districts.

Several lakes, some of which are of considerable extent, are found in the province; and the chief rivers are the Sare, the Laybach, and the Gurk, to the first of which the others are tributary streams, and discharge their mingled waters into the Danube at Belgrade. The ores of iron are abundant in some places, and one mine furnishes excellent materials for the manufacture of steel. Mines of lead and copper have been also wrought; but the rich mines of quicksilver in Idria are by far the most famous and most productive. They were discovered in 1497.

Wheat, barley, and rye, with millet and buckwheat, which latter is raised on the lighter soils, are among the cultivated crops. Flax and hemp are also objects of culture; and some of the rich fruits of warmer climates are produced in abundance. The pastures afford support to numerous herds of cattle and large flocks of sheep. The breed of horses is of middle size, but strong and hardy. The production of silk also gives occupation to the industry of the inhabitants.

The population of the whole duchy is stated at 433,000. The working of the mines, iron forges, glass-making, delft-ware, tobacco-pipes, woollen stuffs, and hosiery, spinning-works, and lace and linen manufactories, afford employment to a large proportion of the inhabitants. Iron, steel, quicksilver, wines, olive oil, olives, and other fruits, honey, cheese, horses, cattle, linen and woollen stuffs, with various ingenious works in wood, constitute the principal exports from the province; but grain, of which the quantity raised is not sufficient to the demand, is imported. The chief towns are Laybach, Trieste, and Ydria, or Idria.

Laybach is the capital, is accounted a fine town, with some elegant houses and public edifices, is traversed by a navigable river of the same name, and contains about 20,000 inhabitants.

Trieste is the chief port of rendezvous for the Austrian marine, is the point of communication between the empire and the different ports of the Mediterranean. The town is well built; the streets are spacious; and the number of vessels, amounting to more than 5000 annually, which frequent its port, which is safe and commodious, is a sure indication of the extent of the trade. *Idria*, with nearly 4000 inhabitants, is chiefly connected with the mines of quicksilver in its vicinity.

CARNIVAL, a grand festival, or season of rejoicing, which is observed in different parts of Italy, and particularly at Venice, and usually commencing from the twelfth day, and continuing till Lent. Feasts, balls, operas, concerts of music, and all kinds of amusement, are exhibited in carnival time. With such attractions, which are peculiarly imposing at Venice, strangers resort to it from all quarters; and, on some occasions, not fewer than 30,000 visitors have been within the city at the same time.

CAROLINA, NORTH, one of the United States of America, has for its boundary on the east the Atlantic Ocean, Virginia on the north, and on the south and west, South Carolina, Georgia, and Tennessee, is about 450 miles long, and 180 miles at its greatest breadth, and includes a superficial area of 34,000 square miles. A dead level, covered with thick forests, extends 60 miles from the sea coast, and is succeeded by a varied surface of mountainous scenery, which brings into view a rich country towards the westward, clothed with stately and extensive forests, and watered by the copious stream of the Tennessee. The soil in the flat districts is rich and fertile; in the western tracts of the state the finest kinds of timber are inexhaustible; and in the mountainous regions, the grain of the northern climates is successfully cultivated.

The diversity of climate is considerable in North Carolina. In the flat and swampy districts, fevers and inflammatory diseases are prevalent; but in the hilly country the air is pure and salubrious; and the inhabitants enjoy all the vigour of life to advanced age

The Chowan river has its origin in Virginia, and having received in its course various tributary streams, is three miles broad where it falls into Albemarle sound. The course of the Roanoke is long and rapid, full of water-falls, and is only navigable for small vessels about 60 miles from its mouth. It terminates in the same sound. The Pamlico or Tar river, which flows into Pamlico sound, admits vessels which draw not more than nine feet of water forty miles of its course. The Neus river also falls into Pamlico sound, and is navigable for ships of considerable burden for twelve miles beyond the town of Newbern, for small craft fifty miles, and for boats 200 miles. The fine stream of the Tennessee traverses the western districts of North Carolina, and at last joins the Ohio.

The population of North Carolina exceeds 563,000. The inhabitants are commended for their hospitality, but they are charged with indolence and excessive dissipation; they are chiefly employed in husbandry. Wheat, rye, barley, oats, and Indian corn, are the principal kinds of grain which are cultivated. In some places flax and cotton are raised. Pitch, tar, and turpentine are extracted from the lofty pitch pines which abound in the plains. The chief commercial intercourse is with the northern states, the West Indies, and Europe. The chief towns are, Wilmington, Newbern, Edenton, Halifax, Hillsborough, and Fayetteville. Wilmington has the best harbour in North Carolina, to which ships of 300 tons burden are admitted, and it enjoys the greatest trade. Newbern stands on the river Neus, where it joins the Trent, and about 100 miles from the sea. Edenton is built on the banks of the river Roanoke, near the point of Albemarle sound. The river admits ships of 150 tons burden to this place.

CAROLINA, South, one of the United States of America, has North Carolina for its boundary on the north and north-east, Georgia on the south and south-west, and the Atlantic ocean on the east, includes an area of nearly 2,500 miles, and forms two natural divisions, distinguished by the names of upper and lower. A plain, stretching 100 miles westward from the Atlantic ocean, and covered with thick forests, level fields, and swampy soil, is succeeded by an undulating range of sand hills. A fertile, well watered, and well cultivated tract called the *ridge*, so named from its elevation, presents a lofty front to the eastward, and extends towards the west, beyond which an agreeable variety of hill and dale land is seen. Some of the mountains in the western district rise to a considerable height. Table mountain is 3000 feet from its base, and 4000 feet above the level of the sea.

The rivers of South Carolina are numerous, and where they traverse the flat country, their banks are generally swampy, but some of them, as Broad river, Coosaw, and Port-royal, are rather to be considered as arms of the sea, and have a sufficient depth of water for large ships. The Pedee, Black river, Santee, Wandow, Cooper, Ashley, and Savanna, are all navigable in some part of their course.

The soil of this state, which is swampy or alluvial, is extremely fertile. Little wheat, barley, or other grain is raised. Tobacco thrives well, but has not been extensively cultivated. Rice, indigo, and cotton may be considered as the staple produce. Fruits of all kinds are abundant. Beside domestic animals, squirrels, bears, wolves, and some other quadrupeds, with a great variety of beautiful birds, are common. The rivers and sea coasts afford inexhaustible stores of excellent fish.

The inhabitants of South Carolina, the number of which is stated at 250,000, are distinguished into four classes;—the planters, who have the largest incomes, and who can afford to live in the most expensive and luxurious style;—the farmers, with more limited resources, are more engaged in the labours of industry, and possess more moderate habits;—the cottagers, who were formerly in a depressed state, but now enjoy a larger share of the comforts of life;—and the squatters, who have been always troublesome neighbours, form temporary settlements, and live chiefly by hunting or plunder; but their condition, also, with regard to their moral and religious habits, has been greatly ameliorated by the exertions of the methodists.

The principal commodities of exportation are rice, cotton, indigo, and tobacco, with some Indian corn, staves, shingles, rosin, turpentine, and salt provisions. The principal towns of the state are Charlestown, Beaufort, Georgetown, Columbia, and Camden.

Charlestown stands near the confluence of the Cooper and Ashley rivers, and was founded by a colony of emigrants from England in 1680. The chief streets run in a straight line between the two rivers, and are intersected by other streets nearly at right angles. The exchange, state-house, armoury, and some hospitals, are the principal public buildings, and some of the private houses are not destitute of elegance. The population exceeds 16,000, of which the slaves compose nearly one-half. The trade of Charlestown is considerable; and for more than 100 years it continued to be the seat of government, but it has been changed to Columbia.

Beaufort stands on the island of Port-Royal, has a good harbour, and has the advantage of a college, established in 1795. *Columbia* became the seat of government in 1801. A college has also been founded at this place, and in 1809 was attended by nearly 90 students.

CARPATHIAN, or Krapack Mountains, an extensive and elevated chain, which forms the boundary of Hungary on the north and east.

CARPENTRY is the art of framing and joining pieces of wood, for the purposes of architecture. See Architecture.

CARPET, a kind of woollen stuff which is usually fabricated of different colours, and is commonly employed for covering the floors of rooms. See Cloth Manufacture.

CARPINUS, the Horn-Beam, a genus of plants belonging to the Monœcia class.

CARPOCRATIANS, a sect of the ancient Gnostics, which derives its name from Carpocrates, who revived some of their opinions in the second century.

CARRIAGE, a general denomination of every kind of vehicle which is furnished with wheels.

CARRICK, the southern district of Ayrshire in Scotland, presents great variety and inequality of surface, from which a great proportion is only adapted for pasturage. The chief rivers are the Girvan and Stinchar. The banks of the first are well wooded, and adorned with many beautiful seats of the chief proprietors.

CARRICKFERGUS, an ancient town and capital of the county of Antrim in Ireland, stands on the north side of the bay of the same name, and, according to tradition, was founded by Fergus the first king of Scotland. It seems to have been a place of considerable strength, defended by walls and a castle, which is erected on a projecting rock, and commands the entrance of Belfast loch. A small garrison is still kept at this place. The population is stated at 4000; but since the trade of Belfast has increased, Carrickfergus has declined. The court-house, at which the assizes for the county are held twice in the year, is an handsome structure. Carrickfergus is 9 miles N. E. from Belfast, and 89 miles from Dublin.

CARRON, a river of Stirlingshire in Scotland, which is remarkable for being the scene of several important events, and derives no small degree of celebrity from the extensive iron-works which are established on its banks, and distinguished by its name. See STIRLINGSHIRE.

CARTHAGE, one of the most celebrated cities of antiquity, the great rival of Rome, and capital of the empire of the Carthaginians, was situated on a peninsula near the middle of the northern coast of Africa, not far from modern Tunis, where ruins of the ancient city are still visible. It lies in East Long. 10° 40′, and North Lat. 36° 40′. It appears to have been founded about 970 years before the Christian era, by Elisa, or Dido, sister of Pygmalion king of Tyre, who being compelled to quit Asia by the tyranny of her brother, sailed with several ships and a considerable number of followers to the neighbourhood of Utica, where a Phœnician colony had for some time been established. In the time of its greatest splendour, about 220 years before Christ, the city is said to have been 23 miles in circumference, and to have contained a population of 700,000 souls. It consisted of three parts, *Byrsa*, or the citadel; *Megara*, the town; and *Cothon*, the harbour. It was admirably situated for commerce, had several noble quays, an extensive arsenal, and docks capable of containing above 200 ships. At present little is left but the remains of piers below water, part of a theatre, the ruins of immense water cisterns, and of an aqueduct of prodigious length and massy architecture, by which these reservoirs were supplied.

If we except their enterprising and warlike spirit, by which they maintained the most extensive commercial intercourse with Europe and Asia, and disputed the sovereignty of what was then called the world with the Roman republic, there is nothing in the character and manners of the Carthaginians which merits peculiar notice. They were barbarous, superstitious, and proverbially faithless; offered human victims to Saturn or Moloch, and appear to have had no pretensions to literature, though some eminent literary characters, especially Terence, are said to have been born at Carthage. But they were ingenious mechanics, and expert navigators; and by their voyages, (particularly that of Hanno, noticed under AFRICA,) contributed to extend the geographical knowledge of the globe.

The *government* of Carthage was of a mixed form, having the semblance of a republic, with the spirit of a monarchy. It resembled that of republican Rome in having a senate for legislation, and two chief magistrates called *Suffetes*, who differed from the Roman consuls in being withheld from military command. Both *Suffetes* and senators were elected by the people. A part of the senate, composed of 104 persons, formed the chief court of judicature, and five of this last court constituted a general *court of appeal*. Their military affairs, though superintended by a native general, were conducted by means of mercenary soldiers, and the general was made accountable for the good or ill success of his expeditions. Their *marine* force was always respectable, and their fleets the most numerous and formidable that had appeared before the Romans acquired the skill in naval affairs to which they were led by their contests with the Carthaginians.

History.—The early history of the Carthaginian empire is involved in obscurity and fable. It is understood that its founder, Dido, perished by her own hands, but whether to avoid a hateful marriage with one of the neighbouring princes, or out of despair at being abandoned by the Trojan chief Æneas, is uncertain. It is supposed that the monarchy established by Dido continued for nearly 300 years, a period which forms an inscrutable chasm in Punic history. We know only, that about 500 years B. C. a commercial treaty was entered into between the Carthaginians and the Romans, much to the advantage of the former, and that a few years before this period the Carthaginians had made descents on the opposite islands of Sicily and Sardinia, though without any considerable or permanent success. Soon after the conclusion of the treaty with Rome, the Carthaginians entered into an alliance with Darius Hystaspes and his successor Xerxes, kings of Persia, in consequence of which they fitted out a formidable expedition against Sicily, where the tyrant Gelo had acquired the sovereignty of the petty territory of Syracuse, and Theron that of Agrigentum. These princes united their forces to oppose the Carthaginians; and though the army of the latter consisted of 300,000 men, headed by Hamilcar, an able and experienced general, the expedition proved in the highest degree unsuccessful and disastrous. The general, with the greater part of his army, perished in the field, and nearly the whole of the fleet was either taken by the enemy or destroyed by tempests. This expedition was followed by a treaty between Gelo and the Carthaginians, much more favourable to the latter than could have been expected, but which they embraced the earliest opportunity to infringe. The war was renewed, and the Carthaginian generals carried several of the Sicilian towns by storm and treated the inhabitants with the utmost cruelty. At length, in the 4th century before the Christian era, when Dionysius had assumed the sovereignty of Syracuse, this subtle prince, in combination with the Agrigentines, formed a plan for exterminating the Carthaginian settlers in Sicily and liberating the island from their galling yoke. This plan was completely successful, owing in a great measure to a pestilential fever which broke out in the camp of Hamilcar the Carthaginian general, who had invested Syracuse in considerable force. Weakened by disease, and harassed by the besieged, the Carthaginian army was compelled to abandon the Sicilian territories. Another expedition under Mago ended in a similar manner; and a treaty was concluded, which continued with little interruption during the remainder of the reign of Dionysius the Elder, and the greater part of that of his successor of the same name. But as the Carthaginians still harboured the ambitious design of becoming masters of Sicily, the Syracusans, about 341 years B. C. applied for assistance to the Corinthians, and obtained the aid of that consummate general Timoleon. Under his direction the Carthaginians were repeatedly worsted, and compelled to sign a dishonourable peace. After this, little of moment occurs in the history of Carthage, till the time of Agathocles, tyrant of Sicily, between whom and the Carthaginians a dispute took place about 310 years B. C. Agathocles, though at first defeated, crossed the Mediterranean and invaded the territories of Carthage, where he committed dreadful ravages, and defeated the Carthaginian general in a pitched battle. But at length the tide of success turned against the Sicilian prince, and he was compelled to relinquish his ambitious designs.

Carthage had now acquired extensive territory and high reputation. Her dominion extended along the northern coast of Africa from Cyrene on the east to the straits of Gibraltar, and it is supposed she had now obtained footing in Spain. Her alliance was courted by the Romans, and in the war which this people carried on against Pyrrhus, they were materially assisted by the Carthaginians. But a jealousy soon arose between the two nations, and in consequence of the Carthaginians intermeddling with the affairs of Sicily, and opposing the Romans in an invasion of that island, a contest ensued, which has been distinguished by the name of the first *Punic war*. This war formed the commencement of a long and almost uninterrupted series of hostilities, which finally terminated in the destruction of the city and empire of Carthage. Only an outline of these wars can be given here, as the details fall more properly under the history of ROME. The first Punic war began about 264 years B. C.; and now for the first time the Carthaginians found themselves successfully opposed by sea. In 260 their fleet was defeated by that of the Romans, and they were attacked on land by a powerful army under Regulus. The defeat of this general, however, in 256, raised the spirits of the Carthaginians; but a second naval defeat which their general Hamilcar sustained in 242, B. C. compelled them to sue for peace, the terms of which were extremely humiliating. Thus ended the first Punic war; but Carthage now found herself embroiled with the mercenary troops which had been employed against the Romans. This contest, called by historians the *Lybian war*, terminated in 238 B. C. and the following year an expedition under Hamilcar and his son Hannibal was fitted out for the conquest of Spain. Here they were so successful as to rouse again the jealousy of the Romans; and in consequence of Hannibal laying siege to the town of Saguntum, a Spanish port, then occupied by the Romans, the *second Punic war* began in 219, B. C. In this war the military genius of Hannibal was eminently conspicuous. Passing the Alps he transferred the seat of war to the Roman territories, and successively defeated their generals at *Thrasymene* and at *Cannæ*; but these successes were only transient. He was soon opposed by Scipio; and, after maintaining an unequal contest for 17 years, the Carthaginians found themselves under the necessity of concluding another humiliating treaty. Peace continued between these rival states till the middle of the 2d century before Christ, when the *third Punic war* began, and, after a short struggle of three years, the Romans obtained the sovereignty of Africa.

The history of Carthage, after its destruction by the Romans, possesses little remarkable or interesting. A new city, near the site of the ancient ruins, and under the same name, was built by the Romans, and is represented by Strabo and Pliny as a place of considerable importance. It continued to flourish till the invasion of the Roman empire by the Vandals in the early part of the 5th century, when it was finally destroyed by these barbarians.

CARTHAGENA, a sea-port town of the province of Murcia in Spain. See MURCIA.

CARTHAGENA, a province of the viceroyalty of New Grenada in South America, and also the capital of the same province. See GRENADA.

CARTHAMUS, or SAFFRON-FLOWER, a genus of plants belonging to the Syngenesia class, and of which one species, *tinctorius*, is employed as a dye-stuff.

CASAL, a town on the banks of the Po in Italy, is a place of considerable antiquity, became a free city towards the close of the 12th century, and about the end of the 14th century a royal residence. The population is about 14,000; and some of the ancient and distinguished families are said to be descended from the early Romans. The same name is applied to another town, which is also situated on the banks of the Po, and contains a population exceeding four thousand.

CASAUBON, ISAAC, a learned critic and editor of ancient classical works, was a native of Geneva, and was born in 1559; at an early age gave strong proofs of great facility in the acquisition of languages; and under the tuition of his father, a clergyman in Dauphiny, he made great progress in the Latin tongue. In 1578 he removed to Geneva, in the view of prosecuting his studies, and acquired such interest or reputation as to be promoted, in his 23d year, to the professorship of Greek, which he held for 14 years; and during this period he married the daughter of Henry Stephens, the celebrated printer, and by her had a numerous family of 20 children. Having accepted a chair in the university of Montpellier for the purpose of teaching the same language, he found, in a short time, that he did not enjoy that comfort and happiness which he expected, and embraced the opportunity which offered of visiting Paris, where he had the good fortune of being introduced to Henry IV., was nominated keeper of the royal library, and received a pension from the king, which enabled him to pursue his literary avocations.

The assassination of Henry in 1610 blasted all his hopes; and the rancorous feelings which existed between him and the Roman catholics determined him to accept an invitation from James I. of England, where he was well received by the learned monarch, and greatly esteemed by many persons of rank and literary distinction, was preferred to a prebend at Westminster and to another at Canterbury, and seems to have entered deeply into some literary correspondence concerning events connected with the history of Mary of Scotland. Casaubon died in 1614, and was buried in Westminster-abbey. The Greek and Latin classics which he edited, and of which a catalogue may be seen in *Biographia Britannica*, afford ample proofs of his profound erudition.

CASBIN, or CASVIN, a city of the province of Irak-Ajami in Persia, stands in a wide plain, encompassed by mountains, was once of great extent, and included 100,000 inhabitants; but its splendid buildings and magnificent palaces were destroyed by an earthquake, and now present a heap of ruins. The present population is variously stated at 20,000, 25,000, and even as high as 60,000. Excellent wines and rich fruits are produced in the neighbourhood. Silk and cotton stuffs, a fine kind of tapestry, works of iron and steel, and particularly fire-arms and watches, are manufactured.

CASE, a term in grammar which denotes the different inflections or terminations of nouns, and is expressive of the relation to the objects which they represent.

CASERTA, a city in the district of Lavora in Naples, and is chiefly remarkable for a splendid palace of Charles III. of Spain, which was begun more than half a century ago, and is not yet finished; and the aquæduct, 27 Italian miles in length, which conveys water from the Apennines for the supply of the place.

CASHAN, or KASHAN, a town of the province of Irak-Ajami in Persia, stands in the plain of Cashan, which is bounded by a distant ridge of mountains, some of which are of great height. The palaces, mosques, caravanseras, and market-places, and some sepulchral monuments, are peculiarly distinguished for their magnificence. The population, once nearly double, is now estimated at 30,000. Military weapons, as sabres, poniards, with copper utensils, silk and cotton stuffs, and brocade, are manufactured; and Cashan was once celebrated for its potteries.

CASHEL, a city of Tipperary in Ireland, is the see of an archbishop, and contains about 3000 inhabitants.

CASHEW-NUT, the seed or nut of the cashew-apple. See *Anacardium*, under BOTANY.

CASHMERE, or CACHIMERE, a province of Hindostan, between the 33° and 34° of north latitude, and is nearly 80 miles in length, and from 40 to 50 miles at its greatest breadth, and having the provinces of Lahore and Cabul on the south, has been always celebrated for its fine climate, rich soil, and picturesque beauties, in consequence of which it has received the distinctive appellation of the Paradise of India. The valley is somewhat of an oval form, and is encompassed by hills. Wheat, barley, and other kinds of grain, are cultivated in the more elevated districts; hemp and saffron are abundant; and the grape, from which a white wine is made, thrives well in warm situations. Some of the finer kinds of fruits are produced.

Among the domestic animals, the sheep of this province have been long celebrated for the excellence of their wool. The famous shawls of Cashmere are composed partly of the wool of the sheep and partly of that of the camel. As shawls of this fabric composed a considerable branch of trade, it is said that 40,000 looms were at one time employed in their manufacture.

This district was celebrated in an early period of its history for the learning of its brahmins; afterwards came under the Mahometan dominion; was long subject to a race of Tartar princes; was subdued by Acbar, and afterwards became a province of the Afghan empire.

Cashmere, the capital of the province, stands on the banks of the river Chelum, over which are numerous wooden bridges. The houses are built of brick, connected with wooden frames, and some of them are of considerable height; but the streets are narrow and confined, and covered with filth of all kinds. The vicinity of the place is adorned with fine gardens; and the mosques and pagodas, erected on small hills, form a picturesque scene.

CASPIAN SEA, an extensive inland sea of salt water in Asia, which is bounded by the province of Astracan and Caucasus on the north, and on the other sides by the provinces of Persia, is about 680 miles in length, and varies from 100 to 260 miles in breadth, and included between the 37° and 47° of north latitude. The extent of this expanse of water is supposed to be greatly diminished from its ancient limits. Towards the north and west, the shores of the Caspian are low, flat, and swampy, the water is shallow, and navigation is consequently difficult and dangerous; but other parts of its shores are bold and precipitous, with deep water.

The different ports of the Caspian sea belong to the Russians, the Persians, and the Tartars. The vessels which navigate its waters draw only about 9 or 10 feet of water, and are rudely constructed and unskilfully managed. The Caspian is peculiarly subject to violent storms. Several large rivers discharge their waters into this inland sea, as the Ural and the Volga from the north, and the Kuma, Terek, and some others from the west.

The fisheries of the Caspian present a valuable source of revenue to the different nations which inhabit its shores. The salmon and herrings are excellent. Different species of seals are taken, and the sturgeon, from the roe of which the caviare is made, well known as a commercial commodity from these regions, is abundant. Isinglass is obtained from the same fish. The commerce of the Caspian is very considerable, and extends, by means of canal and river navigation, throughout the Russian empire and the Baltic. The Russians keep several ships of war on this sea.

CASSADA or CASSADA BREAD, a peculiar kind of bread of a very nutritious quality, which is prepared from the root of the *Jatropha manihot*. See BOTANY.

CASSEL, a town in the circle of the upper Rhine, and capital of the landgravate of Hesse Cassel in Germany, stands on the banks of the river Fulda, by which it is traversed, and divided into the old and new town, of which the former covers the largest space; but the streets are narrow and irregular, and the houses are chiefly constructed of wood. In some parts of the new town the streets are spacious and the houses elegant. The principal public buildings are magnificent structures. Fine gardens and beautiful walks adorn the neighbourhood. The population exceeds 20,000; and woollen stuffs, silk and woollen stockings, gold and silver lace, hats, ribbons, delft ware, and porcelain, are enumerated among the manufactures.

CASSINI, JOHN DOMINIQUE, a celebrated astronomer, who was born in Piedmont in 1625. He studied in the Jesuit's college at Genoa; and having read some books on judicial astrology, his attention was directed to make observations on the heavenly bodies, and, from their aspects, had actually begun to predict future events; but in a short time he fortunately withdrew from these idle dreams, and proceeded in the more solid path of useful science. In his 25th year, he was nominated professor of astronomy at Bologna, and he continued to discharge the duties of that situation for several years, while his leisure hours were devoted to promote and improve the science which he taught. During his residence in Bologna, he constructed the famous meridian line in the church of St Petronius, which he examined 40 years afterwards, and found that it had not varied.

The reputation which he had acquired by his observations and works on astronomy, procured for him an invitation from Louis XIV. of France, to become a member of the French academy. Cassini declined the offer, till he obtained the approbation and consent of the Pope and the senate of Bologna, with permission to be absent six years. On his arrival in France in 1669, he was appointed astronomer royal. He continued in France during the remainder of his life, which was laboriously employed during the long period of 41 years in astronomical observations, the results of which appeared in the Transactions of the Academy. During the last years of his life he had the misfortune to be deprived of his eyesight; and he died in 1712, when he had reached the 87th year of his age.

CASSINI, JAMES, was also an eminent astronomer, and youngest son of the preceding, was born at Paris in 1677, acquired great reputation as a mathematician at the early age of 15, and while in his 17th year he was admitted a member of the academy of sciences. In 1696, during a visit to England, he became acquainted with Newton, Halley, and other distinguished geometers. In 1712, he succeeded his father in the royal observatory of Paris, and few years of his life afterwards elapsed without the production of some work on astronomy, or other subjects connected with physics. His researches were particularly directed to the method of determining the longitude of places by the eclipses of the fixed stars and planets, by the moon, the magnitude and distance from the earth of the fixed stars, and the magnitude and figure of the earth. In 1740, he published *Elements of Astronomy*, accompanied with tables. In consequence of a fall from a carriage, he died in 1756.

CASSINI, DE THURE CÆSAR FRANCOIS, the third in succession of the same family who were distinguished as astronomers, was the second son of James Cassini, and was born at Paris in 1719. To the celebrated mathematicians, Maraldi and Camus, he was indebted for his elementary knowledge of geometry and astronomy; and, like his illustrious relatives and predecessors, he gave early indications of great talents for physical researches; for in his tenth year he calculated the phases of the eclipse of the sun that took place in 1727. In the construction of a general chart of France, he was charged with making the requisite preliminary survey, of which an account was published in the Memoirs of the Academy for 1744. During the war in Flanders, he collected materials for the construction of a similar chart of that country; and twenty years afterwards, in consequence of an invitation from the emperor of Germany, he continued the survey to Vienna. Extending his plan, Cassini proposed to connect the British isles with the general chart of France, a project which has been many years in progress. He made additions to the astronomical tables of his father, published three almanacks in the year 1770, and was the author of 70 papers in the Memoirs of the Academy, all of which are connected with astronomy. He was seized with the small pox, and died in September 1784, when he had reached the 71st year of his age.

CASTALIO, SEBASTIAN, a learned French writer, was born at Chatillon, on the banks of the Rhone, in 1515. He enjoyed the intimacy and friendship of Calvin about the year 1540, during his residence at Strasburgh; and through the recommendation of that divine, he was promoted to a professorship at Geneva. Some diversity of opinion in theological matters, made it necessary for him to resign his situation at the end of three years, and returning to Basle he was appointed professor of Greek. He died in 1564. Castalio is best known as the author of an elegant translation of the Bible in classical Latin, which was printed at Basle in 1551, and was dedicated to Edward VI. of England. He also translated the Scriptures into the French language, and was the author of four books of dialogues, in which the principal histories of the Bible are detailed.

CASTILE, two extensive provinces, or former kingdoms of Spain, distinguished by the appellations of *Old* and *New*.

OLD CASTILE is of a very irregular triangular form, of which the longest side is on the west, where it is separated from Leon by the mountains of Guadarama, with the provinces of Asturias and Biscay on the north, Arragon and part of Navarre on the east, and New Castile on the south. The extent of this province is estimated at 18,272 square miles.

In its *general aspect* it is rather flat, though surrounded, and in some places intersected, by mountains of considerable elevation. These mountains are ramifications from the Pyrenean chain, though they are

Castile.

distinguished by particular names, as the Guadarama, the Sierra d'Occa, the Sierra de Gogollos, and the Sierra Piquera. Its principal lakes are those of San Vicente and Santa Casilda. It abounds with rivers, having, besides the large streams of the Douro and Ebro, which pass through it, above twenty tributaries, distinguished by particular names. Hence there is less occasion for canals in this province, and indeed there is only one, which was begun in 1753, and has never been completed.

The soil of Old Castile is in general rocky, but in some parts of the province so rich and humid, as, notwithstanding the heat and dryness of the climate, to be capable of producing luxuriant crops.

Natural history.—The mineral productions are of considerable value. Besides mines of copper and iron, there are traces of gold about two leagues from the mountains of Guadarama. A fine black veined marble composes great part of a mountain between Aspietia and Vidana, and jet is found near old Colemar. A beautiful transparent quartz forms a narrow bed of near half a league in extent, in the neighbourhood of Mata; and there are several salt springs, especially one forming a small lake at the summit of mount Arandillo, where also are found fine specimens of the petrifactions called Ammonites, or *cornua ammonis*, in a bed of limestone. There are numerous mineral waters and some tepid springs. The province is not remarkable for its vegetable productions. Wood is scarce, and is confined chiefly to the banks of the rivers; though in some places there are fine plantations of poplar, elm, and chesnut, and a few districts furnish luxuriant vintages. Among the animals, the most remarkable are the cattle, sheep, and mules. The flocks are numerous, and produce wool of the finest quality; and such is the goodness of the cows and the quality of the pastures, that vast quantities of butter might be produced in this province. Bears and wolves are found in the mountainous parts.

Population.—This province was formerly extremely populous; but at present the number of its inhabitants appears not to exceed 1,200,000, of whom about 146,000 rank among the nobility of Spain.

Divisions.—Old Castile is subdivided into the districts of Burgos on the north, Segovia on the south-east, and Avila on the south-west. The number of parishes in the whole province is 4,555. The principal towns are Burgos the capital, Osmar, Avila, Valladolid, Segovia, Calahorra, and Soria, which have the rank of cities, and Sogiono, Santo Domingo, De la Calzada, Granou, and Acofra. These we shall now briefly describe.

Burgos is situated on the right bank of the river Arlançon, having suburbs on the opposite bank, connected with the city by three stone bridges. It is the seat of an archbishop, and was formerly very populous, though the present number of its inhabitants scarcely amounts to 9000. It is surrounded with a high wall, whose foundations on one side are washed by the river. Its streets are narrow and crooked, and there is only one square deserving particular notice, where the houses are of genteel appearance, and have piazzas before them. The public buildings consist chiefly of the cathedral, an excellent specimen of Gothic architecture, enriched by valuable paintings, the convent of Las Huelgas, the monastery of Augustines, famous for an ancient crucifix, the palace of Velasco, the hotel de Ville, the hospital del Rai, and a triumphal arch raised to the memory of Fernando Gonzales, first count of Castile. Considerable remains of the old castle, a place of great strength, still exist. It contains about 9000 persons. Almost the only manufacture is that of fine woollen stockings, and the chief trade of the city consists in the exportation of fine woollen cloths. There are here a college for the education of young men, and an academy; and an unsuccessful attempt has been made to establish a surgical school. This city is 112 miles N. of Madrid, and lies in W. Long. 3° 38′, and N. Lat. 42° 10′.

Osmar, though formerly an episcopal city, is now in such a depressed condition as scarcely to deserve the name of a town. It is situated on the Douro, about 80 miles N. E. of Madrid, in W. Long. 2° 12′, and N. Lat. 41° 30′.

Avila, is also an episcopal city, situated in an extensive and fertile plain, on the banks of the river Adaja, is surrounded with a strong wall 9075 feet in circumference. It is well built, is adorned with a handsome cathedral and a college, and has a manufacture of excellent broad cloth. It is 40 miles N. W. of Madrid, and in W. Long. 4° 35′, and N. Lat. 40° 45′

Valladolid is one of the chief cities of Spain, a bishop's see, and the seat of a university. It is seated between two small rivers, near their confluence with the Douro, is encompassed with walls, and is well and regularly built, containing several handsome streets, and elegant squares. Among the public buildings are the cathedral, the college, the royal palace, the Dominican church, and not fewer than 70 monasteries or convents, with numerous churches and chapels. One of the seven Spanish courts of judicature is held at Valladolid. Population about 20,000. It has manufactures of woollen cloths, and an academy for drawing and mathematics. It is surrounded with vineyards, orchards, and corn fields. It is 95 miles N. W. of Madrid, and 52 S. W. of Burgos, in 4° 25′ W. Long. and 41° 51′ N. Lat.

Segovia is built on two hills and an intermediate valley, near the river Alrayadda, and is surrounded by a strong wall flanked with towers and ramparts. It is a bishop's see, and was once the seat of government of the Gothic kings. It is one of the most populous cities of Spain, and is adorned by numerous fine buildings, especially the Alcazar, or royal castle, the cathedral, having a great altar decorated with the finest Granada marble, and containing a massy silver statue of the Virgin, the royal chapel, the mint, and one of the finest and most perfect specimens of Roman architecture; an aquæduct, 3000 paces in length, and supported by 177 lofty arches, by which the city is supplied with water. Population about 10,000. Segovia has a manufacture of the finest Spanish cloths, and another of fine paper. There is here a military school for the instruction of artillery officers. It is 45 miles N. W. of Madrid, W. Long. 3° 44′, N. Lat. 40° 57′.

Calahorra, is a bishop's see, and is placed on the

Castile. side of a hill, extending to the Ebro, 70 miles E. of Burgos. W. Long. 2° 7′, N. Lat. 42° 12′.

Soria is also an episcopal town, built near the source of the Douro, 74 miles S. E. of Burgos. W. Long. 2° 2′, N. Lat. 41° 48′.

In Old Castile agriculture is at a very low ebb. The peasants are naturally indolent, and, from the badness of the roads, there is considerable difficulty in disposing of the superabundant produce. There is much wine produced, but it is very inferior to that of other provinces. A considerable quantity of madder is cultivated and prepared for the use of the dyer. The principal manufactures of this province are woollen and linen cloths, paper, leather, and glass; but much of its wool is exported to France. Its principal imports consist of almonds, figs, rice, needles, brass nails, oil, flax, hemp, worsted stockings, and saffron.

The inhabitants of Old Castile are characterised as grave, silent, and unsociable, but honest, obliging, and disinterested.

The monarchy of Spain commenced in this province. The Castilians, in the beginning of the 10th century, revolted from the tyranny of Orduno, king of Leon, to whom they were first subject, and formed themselves into an independent state under the count Gonzalez. His great grand-daughter having married Sancho, king of Navarre, united this province to his kingdom, and in consequence Sancho assumed the title of king of Castile, in 1028. Old Castile long continued the chief province of Spain, till Charles V by transferring the seat of government to Madrid, obliged it to give place to its sister province.

New Castile, the largest province in Spain, is bounded on the north by Old Castile, on the east by Arragon and Valencia, on the south by Murcia and Andalusia, from which it is separated by the mountains of Sierra Morena, and on the west by Estremadura, and part of Leon. Its superficial extent is estimated at about 22,000 square miles.

The general appearance of this province is beautifully diversified by hills and plains, the latter being well watered by rivers, and intersected or surrounded by mountainous ridges, of which the chief are those of Guadaloupe and La Sarena, on the side of Leon, the Sierra de Cuença towards the east, supposed to be the highest land in Spain, the Sierra de Molina, D'Albarazin, and de Guadarama, which last forms its northern boundary. Its lakes are of more importance than those of Old Castile, but still not numerous. The principal are Tobar and Beteta, upon mount Barbaxeda. The chief rivers are the Tagus, the Iaco, and Guadiana, which are navigable, and the Guadarama, the Molina, the Manzanares, and the Moscas, with numerous other smaller streams.

New Castile is remarkably bare of wood. The soil is thin but extremely fertile, and capable of producing most abundant crops, especially as the climate is warm and serene.

Natural History.—Few parts of Spain abound more in mineral riches, though metallic ores are rare. The chief minerals are, marble of various colours, rock salt, and some coal, especially on mount Barbaxeda, where also there is a copper mine. A large emerald has been found at the foot of the Guadarama, and fossil shells are common near Maranchon. There are several mineral waters, both hot and cold; and in the Sierra de Cuença are some extraordinary caves. Among its vegetable productions may be enumerated the olive, the pine, several species of oak, especially one on which the insect used in dyeing is found, the poplar, the elm, and the crocus from which saffron is made. The animals are similar to those of Old Castile, but the lynx and the ibex are occasionally seen in the mountains of Cuença. The lakes abound with tench and other fresh water fish, and are frequented by numerous flocks of water-fowl, especially teal and wild ducks.

2

Population.—This province is not even so populous as Old Castile. Laborde estimates the number of inhabitants at 1,146,809, of whom 12,687 belong to the nobility.

Divisions.—This province, like the former, has three subdivisions. Toledo on the west, Cuença on the east, and La Mancha on the south. There are in this province 1,301 parishes, 375 religious houses, 116 hospitals, three universities, 50 schools, six cities, and 754 towns. The chief places are Madrid, Toledo, Cuença, Ocana, Talavera de la Reyna, Alcala de Henarez, Laguardia, Tarragona, Aranjuez, Guadalaxara, Seguenza, and Ciudad Real.

Madrid—though now the capital of Spain, was formerly a small and insignificant town. It is built in an extensive plain on the banks of the small river Manzanares; but as it has low walls and no proper suburbs, the approach to it is known only by its numerous towers and steeples. Over the river are two large and handsome bridges, but the stream is so shallow as in general to be easily forded by horses and carriages. The interior of the city has a handsome appearance, as the streets are straight and spacious, and the houses pretty regular, and frequently ornamented with balconies and piazzas, though built only of brick. There are 42 squares, but they are not regular. In one of the largest and most uniform is held the public market, and in the same place are exhibited those barbarous spectacles called bull-fights. Most of the streets and squares are adorned with fountains. The city has fifteen gates, and two of these form the extremities of a spacious and fashionable walk, called the *prado*, constituting the general promenade for all ranks of the inhabitants. The principal public buildings in Madrid are, the palace, standing on an eminence of a superb appearance, and possessing a considerable collection of paintings of the Spanish school; the royal residence of Bueno Retiro; and the armeria, or arsenal, containing a great variety of ancient and foreign warlike weapons. There are 35 monasteries, 31 nunneries, and 39 colleges, besides hospitals, or other charitable institutions. There are also four literary academics, and a royal library. This city contains 18 parishes, between 7 and 8000 houses, and about 146,000 inhabitants. The streets are remarkably clean and well lighted. The manners and dress of the citizens have something peculiar. The men wear cocked hats, and smoke segars in the streets, and, for their accommodation, boys are continually running about with burning torches. The ladies wear half veils, and are affable and unaffected without being immodest. This city lies in W. Long. 3° 12′, and N. Lat. 40° 25′.

Toledo is situated in a narrow valley, surrounded by lofty mountains, on the banks of the Tagus. It is built on the sides and top of a rock of granite, and is entered by a bridge of considerable height. Its general appearance is unpleasant, the streets being narrow, crooked, and uneven. It is an archbishop's see, and has an elegant cathedral, a superb alcazar, or palace, with numerous churches, a neat town house, an archiepiscopal palace, and several hospitals. There are four gates, two bridges, and two public walks. It contains about 20,000 inhabitants, and is remarkable for its manufacture of sword-blades of exquisite temper. There are also made here a few woollen stockings, but its other manufactures have fallen into decay. Toledo is a city of great antiquity, and has successively been the seat of empire to the Gothic, Moorish, and Castilian kings. It is 37 miles south of Madrid, in W. Long. 3° 20′ and N. Lat. 39° 53′.

Cuença, the seat of a bishoprick, and the capital of the sierra of that name, is situated on an eminence between two more elevated ridges, and is surrounded by walls of an extraordinary height, with six gates. The streets are uneven, and so steep as not to be ascended without difficulty, and sometimes danger. It has a noble Gothic cathedral, an episcopal palace, 12 monasteries, several churches, with gates of remarkable workmanship, and a magnificent bridge over the Huecar. It is supposed to contain 6000 inhabitants, has a seminary, and three colleges, three hospitals, and is divided into 13 parishes. It has a small woollen manufactory, and large quantities of wax and honey are produced in its neighbourhood. It is 74 miles E. by S. of Madrid, in W. Long. 1° 55′, N. Lat. 40° 7′.

Ocana, in La Mancha, is a large town, occupying the entrance of an extensive plain, and contains four parishes, six monasteries, and five convents, and has two public fountains. It was once a large manufacturing town, but there is now only one manufactory of coarse leather and four of hard soap. It is 18 miles east of Toledo, in W. Long. 2° 50′, N. Lat. 39° 52′.

Talavera de la Reyna, an ancient city on the right bank of the Tagus, surrounded with walls, and fortified with turrets and ramparts; is of considerable extent, and stands in a beautiful, well cultivated plain; has a bridge over the Tagus, nine gates, and one large square; but the streets are narrow, and the houses extremely low. It has few edifices deserving notice, and these consist principally of churches. The condition of this place has been much improved by the introduction of numerous manufactures of silk stuffs, soap, hats, porcelain, and gilded articles. Talavera is now remarkable as having been the seat of a great battle fought between the French and combined forces of Britain and Spain, on the 27th July 1809. It is 58 miles S. W. of Madrid. W. Long. 4° 1′, N. Lat. 39° 41′.

Aranjuez, a small but beautiful town on the left bank of the Tagus, remarkable chiefly as being the summer residence of the royal family. It is regularly built, has good streets, some of which are planted with trees, an elegant square, several public edifices, among which are the royal palace, distinguished by neatness rather than elegance, many beautiful walks and fountains, and the environs are laid out in gardens. It is 20 miles nearly south of Madrid.

Guadalaxara is an ancient city, large, but ill built, situated in a plain near the eastern bank of the Henarez, and containing a population of about 12,000 people. It has ten parishes, six monasteries, seven convents, and two hospitals; and among the public buildings, the most deserving of notice is the palace of the noble family of Infantado, built in the form of a pantheon. Here is an extensive manufactory of woollen cloths and serges. It is 30 miles N. E. of Madrid. W. Long. 2° 47′, N. Lat. 40° 36′.

Seguenza, unaccountably placed by Laborde in Old Castile, is an archiepiscopal town, and the seat of a university, situated on a small river that runs into the Henares. It is well built, and fortified with a strong wall. It has a castle and a cathedral. It has a manufactory of calicoes. It is 60 miles N. E. of Madrid. W. Long. 2° 41′, N. Lat. 41° 6′.

Ciudad Real, considered as the capital of La Mancha, is situated in a plain not far from the Guadiana. It is regularly built, has a handsome square, and a manufactory of flannels and coarse woollen cloths. Population between 8 and 9,000. It is the residence of the intendant of La Mancha, and of the grand vicar of the archbishop of Toledo. It is 90 miles south of Madrid; in W. Long. 3° 25′, and N. Lat. 38° 58′.

In the neighbourhood of Madrid is the royal palace of the Escurial, and some miles farther to the north the royal residence of St Ildefonso.

Agriculture.—New Castile is scarcely more advanced in respect of agriculture than the neighbouring province. Some wheat and barley are cultivated, and a considerable quantity of wine is produced, though of inferior quality; but, in general, the land is much neglected, and the practice of irrigation, of which the soil has much need, is scarcely known. Great quantities of wax and honey are collected, and excellent oil might be prepared if sufficient care were taken in its expression.

Manufactures, commerce, &c.—The chief manufactures of New Castile have been noticed in the above description of its towns. Its exports are few, and its imports consist chiefly of articles of luxury. The roads are greatly improved, and much superior to those of Old Castile. If we except the capital, the inhabitants of New Castile are indolent and inactive, haughty and reserved, and remarkable for their ignorance both of literature and the arts.

This province was occupied by the Romans previous to the 5th century, when it was wrested from them by the Gothic chief Altholphus, who fixed his residence at Toledo. It continued under the dominion of the Goths till the fall of Roderigo in the begining of the 8th century, when it became subject to the Moors. It was finally united to the Spanish monarchy in the 11th century.

CASTLETOWN, a town of Derbyshire in England.

CASTLETOWN, the capital of the isle of Man. See MAN, ISLE OF.

CASTS, OR CASTES, is the appellation of the four great tribes into which the native inhabitants of

India have been divided from the remotest periods of antiquity. The first cast is that of the Brahmins, and is accounted the most sacred, and those belonging to this cast are the priests and philosophers of the country. The government and defence of the state are entrusted to those of the second cast or tribe, called *Ketri* in the native language. From this cast are selected the magistrates and rulers of the nation, the generals and soldiers of the army. The third tribe or cast, called *Byse*, includes the husbandmen and merchants; and under the fourth, denominated *Sudra*, are comprehended the artizans, labourers, and servants. Flagrant misconduct, as the violation or neglect of religious duties, subjects the guilty person to a kind of excommunication from all intercourse with his tribe. The *Pariars*, the appellation of such excommunicated persons, are reduced to a wretched condition. In some parts of India, if a pariar approach a warrior of high cast, the latter may put him to death with impunity. Even the shadow of those vile beings passing over what is to be used for meat or drink, is supposed to defile it. Of these casts, the Sudra, or artizans and servants, are the most numerous; and the three higher casts are supposed to amount to no more than a fifth part of the whole population. According to the institution of Hindoo society, the same family and all its descendants are bound to follow the same professional employment; and hence arises the great perfection which mechanical operations in different arts have reached in India. But this limitation to particular trades and professions is now less scrupulously observed, particularly in those parts of the East which are under the jurisdiction of a foreign government, and persons belonging to a higher cast are found exercising the menial offices of the lowest.

CATS-EYE, a gem or precious stone belonging to the siliceous genus of minerals. See GEOLOGY.

CATACOMB, a subterraneous gallery or chamber for the reception of the dead. From the natural anxiety which exists in the human mind for the disposal of the bodies of departed friends, places of this kind have been constructed by different nations. In ruder periods of society, the bodies of the dead were deposited in natural caves; but when such were wanting, artificial excavations were made. The most ancient and the most celebrated catacombs are those of the Theban kings, which are known to have existed for more than 3000 years. The chain of mountains in the vicinity of Thebes is excavated to nearly three-fourths of their height, and includes a prodigious number of entrances, which lead to an almost endless number of catacombs. The walls, throughout their whole extent are covered with paintings and hieroglyphics, which still exhibit all the freshness of the original colours. Some of these catacombs are particularly described by the French travellers who attended the army of Bonaparte during his invasion of Egypt; but it appears that these depositaries of the dead have been long ago violated, and all the bodies have been carried off.

The catacombs of Rome are also long subterraneous galleries intersecting each other at right angles, or going off in an oblique direction. By openings from above, a feeble glimmering of light is admitted, and on each side are seen cavities which are supposed to have been destined for lamps. The bodies were disposed in niches formed in the walls, and they were arranged in regular rows above each other. Each niche was closed at the foot with a single brick, and the cement with which it is secured is yet seen in good condition; and when some of these bricks which closed the tomb were removed, the skeletons were found nearly entire.

Catacombs have been found in other parts of the world, as at Syracuse, where the excavation forms regular parallel recesses and chambers, with a flat circular roof, and an opening at the top for the admission of light; at Malta, where they are cut in the rock with small narrow galleries; and in Syria and Palestine, to which a large flat stone, moved on pivots for hinges, forms the door.

From the belief which prevailed among the Egyptians, that the soul would be reunited to the body, if the latter were preserved entire, it is supposed the practice of embalming and the use of other means to secure it from decay have originated. But the catacombs have not been solely confined to the reception of the bodies of men. Mummies have been made, by the ancient Egyptians, of the bodies of various animals, as jackals, crocodiles, birds, and fishes, and have been consigned to these repositories of the dead. In particular, the ibis, or sacred bird of the Egyptians, is found in great preservation, and exhibiting the rich colours of its plumage.

CATALONIA, a province of Spain, occupying the north-east angle of that peninsula. It is bounded on the north by the Pyrenean mountains, which separate it from France; on the east and south-east by the Mediterranean; on the west by the province of Arragon; and on the south-west by that of Valencia. Its extent in square miles is estimated at 10,400.

General aspect.—The general appearance of this province is irregular and mountainous, having, however, several rich and fertile plains and vallies, watered by numerous rivers. Wood is here more plentiful than in many other provinces in Spain. The mountains of Catalonia are ramifications of the Pyrenees. The principal are those of Montserrat, rising about 3300 feet above the level of the sea, and remarkable for its lofty, rugged, and naked cliffs, Mon-Negre, Valgorguina, Sangran, Alsinellas, Requesens, and Monseny. Among the numerous rivers which flow through this province may be particularised the Ebro, the Lobregat, the Ter, the Noya, and the Cervera. Of these the Ebro is the largest and most navigable, disemboguing itself into the Mediterranean, near the south-western extremity of the province. Catalonia has numerous canals, but these serve rather for watering the fields than for the purposes of navigation.

The soil is generally thin and rocky, and in some parts so scanty as to require a considerable addition brought from other places. The climate is keen and healthy.

Natural history.—A great quantity of mineral productions occur in Catalonia. There are mines of iron, lead, copper, tin, antimony, and silver, and even one of gold. Coal and salt are very common, and in particular there is a considerable mountain in the neighbourhood of Cardona, composed entirely of salt. Marble of various kinds is very common, and near Vray are found amethysts and topazes. Nor is this province less rich in vegetables. Trees of most kinds, especially evergreens, are found in tolerable abundance, and not fewer than 437 species of plants are enumerated as found on the mountain of Montserrat; the vine and the olive grow well, and nuts and other fruits are produced in great quantity. The mules of Catalonia are remarkable for their strength and the security with which they traverse the mountainous districts. Bears and wolves are not uncommon in the higher regions.

Population.—The total number of inhabitants of this province is computed at 814,412, and of this number 1266 are nobles.

Divisions.—There are two subdivisions of Catalonia, denominated the counties of Roussillon and Cerdagne. The province comprehends an archbishoprick, 7 bishopricks, 22 abbeys, enjoying nearly episcopal privileges, one grand priory, 2,738 parishes, a university, 14 cities, and 283 towns, of which five are seaports. Barcelona, the capital, has been already described under its proper name. The following towns are most deserving of notice, viz.

Tarragona—the seat of an archbishop, is a place of considerable importance, chiefly on account of its antiquity. It is built near the small river Francoli, near the place where it falls into the sea, upon a very elevated rocky ground. It is surrounded with walls, and has a harbour flanked with bastions. Its streets are narrow, crooked, and irregular, without squares, but it has several handsome edifices. The cathedral is an elegant Gothic structure, with numerous internal ornaments. There are several neat chapels, and two castles of little importance. This city is extremely deficient in the necessary article of water, there being neither wells nor fountains, so that the inhabitants are supplied partly from rain water kept in cisterns, and partly from distant springs by means of an aquæduct. There are several remains of Roman architecture, especially the walls built by Scipio, the aquæduct, nearly seven leagues long, a palace, a temple, and an amphitheatre. It contains about 9000 inhabitants. There are here considerable manufactures of silk and cotton goods, and the wine produced in its neighbourhood is of excellent quality. Tarragona was the seat of government of the Roman Tarragonese province. It is 220 miles N. E. from Madrid, and lies in E. Long. 1° 13′, and N. Lat. 41° 51′.

Urgel—a bishop's see, and formerly capital of a province of the same name, is situated in a fertile plain near the river Segra, 75 miles N. W. of Barcelona, in E. Long. 1° 44′, and N. Lat. 42° 32′.

Lerida—a bishop's see, and the seat of a university, one of the most ancient cities in Spain, is built on a rising ground on the banks of the Segra. It contains about 18,000 inhabitants. Here several important battles have been fought, both in ancient and modern times, particularly between Scipio and Hanno during the Punic wars, and between Julius Cæsar and the armies of Pompey. It has a fine bridge over the Segra, and its environs are highly interesting. It is 200 miles N. E. of Madrid, in E. Long. 45′, and N. Lat. 41° 44′.

Gerona—an episcopal city built on the side of a mountain on both banks of the river Ter. Its chief public buildings are the cathedral and collegiate church. It contains about 14,000 inhabitants, and is also a place of great antiquity. It is a fortified place, and has sustained several sieges. Its chief manufactures are those of cotton stuffs and worsted stockings. It has a college, generally frequented by about 900 students, and several institutions for the education of females. It is about 16 Spanish leagues from Barcelona.

Tortosa—a bishoprick and university, is built on a fertile plain on the banks of the Ebro; it has strong walls, and a large but ruinous castle. The cathedral is an elegant building, with the usual ornaments of Catholic churches, and there are several religious houses and public hospitals. Its manufactures are of some importance, and consist chiefly of hard and soft soap and common porcelain. This city was also a Roman station, and was called Dordosa. It is 180 miles E. of Madrid, in E. Long. 35′, and N. Lat. 40° 53′.

Figueras—a small but strongly fortified town, situa- in an extensive plain near the confines of France. It contains about 4000 inhabitants. It is remarkable for a very strong castle, deemed nearly impregnable. E. Long. 2° 46′, N. Lat. 42° 18′.

Igualda—a town of considerable size, surrounded by vineyards, corn-fields, and plantations of olives. It contains about 12,000 inhabitants, and is remarkable chiefly for its manufactures of printed calicoes and excellent fire-arms.

Agriculture.—Notwithstanding the natural disadvantages of the soil of Catalonia, there is no part of Spain where agriculture is better understood or more assiduously practised. Corn of every description, even rice, is cultivated with success, though the quantity of wheat is insufficient for the consumption of the inhabitants. The system of irrigation is carried to a greater extent than in most other countries, and the wine and oil of this province are in considerable esteem. Flax and hemp are cultivated successfully, but the production of wool is scanty. Planting is carried on to a great extent, especially that of cork trees, so that the greater part of Europe is hence supplied with that useful article.

Manufactures, commerce, &c.—Most of the manufactures of Catalonia have been noticed above, or with Barcelona. Besides those there enumerated may be mentioned, gunpowder, aquafortis, sugar-of-lead, brandy in large quantities, various articles of cutlery, and anchors. Its commerce is considerable, the exports consisting chiefly of the productions and manufactures already enumerated, and the imports of corn, wool, and silk. The roads of Catalonia are very bad, but good inns are more common than in most other parts of Spain.

The Catalans are blunt, uncourteous, and resentful, but active, brave, industrious, and enterprising, much given to travel, so that they are found in most parts of Spain, and in several foreign countries. They are remarkable for their independent and warlike spirit.

Catalonia was very early colonized by the Carthaginians, from whom it was wrested by the power of Rome. In the subjugation of the Roman empire by the barbarians, this province, with much of the adjacent country, fell a prey to the Goths, who were compelled for a short time to yield it to the Moors. In the latter end of the 8th century it became a province of France, was afterwards erected into an independent state under the counts of Barcelona. In 1137 it was annexed to the crown of Arragon, and has since, with occasional insurrections and revolts, continued to form a part of the Spanish monarchy.

CATANIA, a city of Sicily, near the foot of mount Ætna, which, under the name of *Catina*, made a conspicuous figure in ancient history, and has not been less known in modern times on account of the dreadful calamities to which it has been subjected by the ravages of earthquakes and the eruptions of Ætna. See SICILY.

CATAPULTA, an ancient military engine which was constructed for throwing stones, darts, and other missile weapons upon an enemy; some of which were of such strength that they were capable of projecting stones of a hundred weight.

CATARACT, a disease of the eye, in which the vitreous humour has become opaque, and produced blindness.

CATECHU, an astringent substance, which is extracted from different plants, and was long distinguished by the name of *terra Japonica*, or Japan earth, because it was supposed to be an earth brought from that island. But it is found to contain a large proportion of tannin, with some extractive matter, and mucilage. It is employed in India as a dye-stuff, in the composition of Betel, and as an ointment; and it is applied in Europe chiefly to medical purposes.

CATEGORY, a well known term in scholastic philosophy, and denoting a series or order of all the predicates or attributes included under any class of thoughts or ideas. Aristotle divided all the objects of human thought into ten categories, namely, quantity, quality, relation, action, passion, time, place, situation, and habit; and this arrangement was long followed in the schools.

CATENARIA, or CATENARIAN CURVE, is formed by a rope or chain hanging freely from two points of suspension.

CATERPILLAR, is the appellation of the reptile or worm state of insects. See ENTOMOLOGY.

CATESBEA, the LILY-THORN, a genus of plants belonging to the Tetrandria class.

CATOPTRICS, is that branch of optics which explains the laws and properties of light reflected from plane or curved surfaces. See OPTICS.

CATULLUS, CAIUS VALERIUS, a celebrated Roman poet, was a native of Verona, and flourished in the time of Julius Cæsar, Cicero, and Lucretius the poet. His residence was chiefly at Rome, where he enjoyed the society and pleasures of the capital. The poems of Catullus, which are chiefly elegiac compositions, were in great estimation among his cotemporaries, and they are distinguished by great tenderness and simplicity. But the indelicacy of his language and allusions is justly objected to. Many elaborate editions of his works have issued from the press on the continent; and in Britain an English translation in verse was published in 1795, along with the Latin text, and with illustrative notes.

CAVALLO, TIBERIUS, a natural philosopher, was a native of Naples, and was born in that city, in the year 1749. His father, a physician, died when the son was only in his 11th year, but the care of his friends enabled him to prosecute and finish an academical education. Originally destined to engage in commerce as the future business of his life, he was sent to England in 1771, for the purpose of improving and extending his knowledge of mercantile affairs. That country became his final residence, and the routine of commercial transactions was soon exchanged for the pursuits of literature and the cultivation of science.

The researches of Cavallo were extended to various departments of natural philosophy; but electricity, which at that time excited great attention, was the first object of his enquiries; and the results of his labours were published in three memoirs in the Philosophical Transactions for 1776 and 1777, and in the latter year, *A Complete Treatise on Electricity*, octavo, appeared, in which is detailed a familiar exposition of the principal facts then known, illustrated by experiments. Mr Cavallo published other works connected with the same subject, as well as on the kindred science of magnetism; *A Treatise on the Air and Permanently Elastic Fluids, and the History and Practice of Aerostation.* He wrote also on the *Temperament of Musical Intervals, and on Factitious Airs, and the Nature of the Blood*; and among the last of his labours are his *Elements of Natural or Experimental Philosophy*, in four volumes *octavo*, and published in 1803. This excellent work embraces whatever is valuable in physical science, and illustrates the various subjects, which are discussed in a popular manner. Mr Cavallo died in 1809, when he had reached the 60th year of his age.

CAVAN, an inland county of the province of Ulster, n Ireland, is bounded on the north and east by the counties of Fermanagh and Monaghan, and on the south and west by Meath, Longford, and Leitrim, is about 51 miles long, and 28 miles at its greatest breadth, and includes an area of 758 square miles. The whole surface of the county presents a mountainous aspect. Numerous lakes appear in the central parts of the county, and some are formed by the expansion of the streams which carry off the waters from the lakes of Westmeath.

The soil is described as poor, and agricultural improvements have not made rapid advances. Oats, potatoes, and flax are the most frequent crops; and the farms, chiefly occupied by manufacturers, rarely exceed 20 acres in extent. Linen was formerly the great object which employed the industry of the manufacturers, but it has given place, in some degree, to cotton fabrics. The population is estimated at more than 90,000; and the population of catholics to protestants is five to one. The county consists of 30 parishes; and being forfeited about the commencement of the reign of James I. it was occupied by a colony of English settlers, many of whose descendants still retain possession of the property assigned to their predecessors.

Cavan—the capital of the county, is not of sufficient importance to require minute description. It is a market and post-town, and has the advantage of

Caucasus. a free-school, for the support of which 570 acres of land were appropriated by charter in the time of Charles I.; but it appears from a late survey that some mismanagement has crept in, for few or scarcely any scholars attend it. *Kilmore* is also a small town in the same county.

CAUCASUS, a government of Russia in the southern part of that empire, and is divided into two provinces, namely, Astracan and Caucasus. The province of Caucasus includes the Cuban and all those districts subject to the Russian dominion between the Black sea and the Caspian, and the Don and Cuban rivers.

The mountains of Caucasus constitute the most striking feature of this region; they extend between three and four hundred miles, from the Euxine to the Caspian sea; the highest part of this elevated ridge is covered with perpetual snow; and hence the allusion which has been made to the *frosty Caucasus*, both in ancient and modern times. The higher mountains are composed of primitive rocks; the summits are of granite; slate-rocks, and limestone, or chalk, appear in the lower regions; rock-salt, and other saline matters, sulphur and alum, are disseminated in the plains; some indications of coal are met with, and some ores of iron, copper, and lead, with a little silver and gold, are distributed in the rocks. Various mineral springs have been discovered in these regions, some of which are cold, and composed of saline ingredients, and some of them are hot, and of a sulphureous quality.

On that side of the mountains which is connected with the Russian territory, the Terek, the Kuma, and the Cuban, are the principal rivers. The Terek, deriving its source from the snowy mountains of Caucasus, and from the most elevated parts of the frontiers of Georgia, proceeds with a rapid course; and in the months of July and August is greatly enlarged by the melting of the snows, and inundates the flat country. In the lower part of its course its banks are destitute of wood; but in the higher regions they are adorned with fine forests of oak and other trees; it becomes less rapid below the town of Kislar, and joins the Caspian by several branches, three of which are navigable for boats. In the lower districts through which the Terek flows, the vine, the mulberry, and other fruit-trees, are successfully cultivated.

The Kuma rises in the same mountains, and, directing its course towards the east, traverses a rich valley; but its waters are lost in the sands before it reaches the Caspian. The banks are clothed with shrubs and reeds, which afford a retreat to an immense number of pheasants.

The Cuban is the largest river of this district, and was called *Hypanis* by the Greeks. Its source is in the highest mountain of Caucasus, and it forms the frontier boundary of the Russian empire. It terminates its course by two branches, one of which falls into the sea of Asoph, and the other discharges its waters into the Black sea. In the island of Taman, from the two branches a canal is cut, which joins the sea of Asoph with the Black sea. This river is enlarged by many tributary streams; in the higher parts of its course the banks are steep and rocky, and in the plains it is navigable for flat-bottomed vessels. It abounds with fish of an excellent quality; and the fisheries afford the chief employment to the inhabitants in the neighbourhood.

This government was separated from Astracan in 1801. The number of inhabitants is stated at 31,579 males, which are chiefly Russians; but among them are also Tartars, Armenians, Georgians, and Cossacks, beside Calmucs and other migratory tribes, who frequent the steppes, or extensive flats, for the purpose of pasturage to their numerous herds and flocks. Honey, wax, furs, hides, fruits of different kinds, and wines, which have lately begun to be objects of manufacture, are the principal productions.

Cave. CAVE, Edward, a printer, and projector of the *Gentleman's Magazine*, the first periodical work of the kind in this country, was a native of Warwickshire, and was born in 1691. His father, disappointed in family expectations, was compelled to follow the trade of a shoemaker at Rugby, at the celebrated free-school of which, at that time in high reputation, young Cave was placed, and, by the quickness of his talents, acquired a decided superiority over his fellows, many of whom were connected with families of the highest rank. But this advantage gave him an invidious distinction, and was followed by such harsh and ungenerous treatment, that he determined to leave the school, and resign the hope of a literary education.

After various attempts to acquire some profession, he went to London and bound himself apprentice to a respectable printer. With little comfort in the society of his master and mistress, who lived in unceasing discord, he persevered in acquiring a knowledge of his business, and was so much master of it at the end of two years, that he was intrusted with the superintendence of a printing-house at Norwich, and the publication of a weekly newspaper. Opposition arose as usual to the new undertaking, and produced a public controversy, in which young Cave acquired the reputation of a writer. At the conclusion of his apprenticeship, he continued to work as a journeyman, and having espoused the principles of the Tories, he was for some years a writer in Mist's *Journal*. He afterwards obtained a place in the post-office, but still exercised his trade during the intervals of attendance. The situation which he held in the post-office enabled him to procure country newspapers, the intelligence of which he sold to a London journalist for a guinea a week. He was afterwards promoted to the office of clerk of the franks, in the management of which his spirit and firmness were greatly applauded, for he often stopped franks when the privilege thus enjoyed seemed to be abused. In this exercise of his office complaints arose, and charges of opening letters to detect them were brought against him; and being cited before the house of Commons for a breach of privilege he was at last dismissed from his place. By his diligence and economy, he collected a sum sufficient to set up a printing-office, and began the Gentleman's Magazine, which long continued to be the most popular, as it was the first periodical publication of the kind in this country; and to the success of this undertaking he was indebted for the ample fortune which he left behind him.

"Cave," says Dr Johnson, his biographer, "began to aspire to popularity; and being a greater lover of poetry than any other art, he sometimes offered subjects for poems, and proposed prizes for the best performance. The first prize was L.50, for which, being but newly acquainted with wealth, and thinking the influence of L.50 extremely great, he expected the first authors of the kingdom to appear as competitors, and offered the allotment of the prize to the universities. But when the time came, no name was seen among the writers that had ever been seen before; the universities and several private men rejected the province of assigning the prize. At all this Mr Cave wondered a while, but his natural judgment, and a wider acquaintance with the world, soon cured him of his astonishment, as of many other prejudices and errors. Nor have many men been raised by accident or industry to sudden riches that retained less of the meanness of their former state.

"The death of his wife produced a strong effect on his health; he lost his sleep and his appetite, and having lingered about two years he died in 1754, after he had concluded the 23d annual collection. His resolution and perseverance were very uncommon; in whatever he undertook, neither expence nor fatigue was able to repress him; his constancy was calm, and, to those who did not know him, appeared faint and languid; but he always went forward though he moved slowly." See *Cave's life* by Dr Johnson.

CAVEAT is a term applied to a process in the ecclesiastical courts of England to stop the proving of a will, and the granting of titles of administration to the prejudice of another; and denotes also the preliminary process which is sometimes followed in applying for a patent to secure the privilege of any invention.

CAVIARE, a preparation of the hard roe of the sturgeon, by forming it into cakes three or four inches in breadth, and about an inch in thickness. It is prepared by separating the membranous covering of the roe, washing it in vinegar, and salting and pressing it. It is then put up in small casks, and becomes a valuable commercial commodity throughout Europe. The best caviare is from the Caspian sea.

CAUK or Cawk, a mineral substance, partly composed of heavy spar and partly of carbonate of lime, and distinguished by this provincial name in Derbyshire.

CAYENNE, or French Guiana, a province of South America. See Guiana.

CAYLUS, Count de, Marquis de Sternay, a celebrated French antiquary, was born at Paris in 1692. His early education was the peculiar concern of parental affection. His mother, who was the niece of the famous Madame de Maintenon, and was equally distinguished for vigour of intellect and sprightliness of wit, undertook the charge of improving his heart in the softer virtues, while his father instructed him in corporeal exercises and in the profession of arms. Having entered the army, he was soon distinguished by his valour, and was at last promoted to the command of a regiment of dragoons. When the peace was concluded he was left without employment; and that he might not remain in a state of listless inactivity, he had a strong desire to visit Italy, where he acquired that taste for antiquities, which became his ruling passion through the remaining part of his life.

In another journey, he directed his course to the Levant, visited Smyrna, and examined the ruins of Ephesus. Among his various researches into the arts of the ancients, his most important discovery is the method of executing encaustic painting. He derived the first hint, it is supposed, from the description of Pliny, and, after many experiments, he found out the secret of incorporating wax with various tints and colours, and of making it obedient to the pencil. Such was the progress by which he discovered the composition, and the colouring of the pictures of ancient Rome. A collection of coloured drawings, taken from antique pictures, had fallen into his possession; and before he placed it in the French king's cabinet, he had the whole engraved, and so finely coloured as to rival the vivid tints of the originals. Thirty copies of this work only were published. Another favourite object of pursuit was to engrave the Roman antiquities, which still remain in the southern provinces of France. In this work he was engaged during his last illness. He died in 1765; and his tomb, which is an ancient sepulchral antique of beautiful porphyry, marks the character of its inhabitant.

CEANOTHUS, New Jersey Tea, a genus of plants belonging to the Pentandria class.

CEBES, an ancient Greek philosopher, and a native of Thebes, flourished about 400 years before the Christian era. It is said that he was an intimate friend of Socrates; but he is best known as the author of a work which is distinguished by his name. The table of Cebes, which exhibits a picture of human life, is familiar even to those who have not made great progress in the knowledge of the Greek language.

CECILIA, St. the patroness of music, of whom many legendary stories are related, lived about the beginning of the third century, had been converted to Christianity, and having suffered martyrdom by being thrown into a cauldron of boiling water, her name was enrolled among the list of saints about the fifth century. According to the tradition, she greatly excelled in music, and hence her story has become a favourite subject for the poet and painter.

CECROPS, was the founder and first king of Athens, and is supposed to have flourished about the time of Moses. He introduced many improvements into the domestic policy of the Greeks, over whom he reigned during the long period of 50 years.

CEDAR, the English name of several species of trees which belong to different genera; but the true cedar, or cedar of Lebanon, alluded to in Scripture history, is a species of pine, *pinus cedrus*, which becomes a lofty tree.

CELEBES, an island in the Indian ocean, of a very irregular form, and separated from Borneo by the straits of Macassar, extending from the 2° of north latitude to nearly the 6° of south latitude, and stated to be about 500 miles in length, and 150 miles in breadth. The coast is deeply indented by three bays, or gulfs, the first of which, called Buggess bay, runs into the island from the southward; another deep gulf penetrates the north-east quarter of the island; and the third, called Tolla bay, is in the eastern district. Three rivers, some of which are of considerable magnitude, traverse the different quarters of the island. The Chinrana, which is the largest, discharges its waters by several mouths into Buggess bay, and is navigable for European ships.

The principal productions of the island are rice and cotton. The latter is manufactured into cloth called Cambays, some of which are of a very fine fabric. Some kinds of silk stuffs are also manufactured, with fire-arms, small brass guns, and works in gold and silver. Prows, or boats of a light construction, are built in the island. In these prows they have commercial intercourse with most places in the eastern ocean. They are often seen on the northern coast of New Holland, where they fish sea-swallo for the Chinese market. Gold collected from the beds of rivers and torrents, at one time in considerable quantity, was exchanged for opium and different fabrics of cloth from Bengal; iron and steel, cotton and rice, are also exported.

The Buggesses, as they are called by the English, and who are the most powerful nation in the island, and the Macassars, are the best known to Europeans of the various tribes which inhabit Celebes. The Portuguese early obtained a settlement near Macassar. They were expelled by the Dutch in 1660. The authority of the latter had been long on the decline, and it finally terminated in 1812, by the reduction of Macassar and Fort Rotterdam by the British forces.

Macassar, the principal settlement of the Dutch, stands on the south-west coast of the island, and is defended by Fort Rotterdam, the walls of which are strong, and constructed of stone. The town lies in an extentive plain, which stretches to the foot of a mountainous range to the eastward. This plain is covered with rice fields and pasture grounds, and is watered by small canals proceeding from the larger springs that descend from the mountains. According to some accounts, the population of Macassar is is stated at 10,000. Rice, sapan-wood, and cadjany are the chief exports from this place; and by a Chinese junk, which arrives annually, nankeens, silk goods, sugar, tea, China-ware, and some other commodities, are imported.

CELLINI, Benvenuto, an eminent Italian statuary and sculptor, was born at Florence in the year 1500. His taste led him to imitate the celebrated productions of antiquity, and in that style, at a very early age, he executed some works in gold and silver, which were greatly admired. He was first employed in seal engraving, cutting dies, modelling, and enamelling. In a war between the French and the head of the church, when the former invaded and captured Rome, Cellini took up arms and signalised himself by his skill and prowess in the defence of the city. He afterwards held the place of stamp-master to the mint, and some other lucrative offices under the pope. But from the violence and ferocity of his temper he was frequently concerned in fatal broils, and in these affrays he killed several persons, from the consequences of which he escaped by temporary retirement, and the exercise of the dispensing power of the pope. Dissatisfied with the patronage which he received from his holiness, he relinquished his service for some time, and travelled in the retinue of Francis I. Here, too, he seems to have been disappointed in his expectations; for he returned to Rome, and was immediately seized and thrown into confinement, on a charge of having purloined some of the jewels of the papal regalia. In attempting to escape from a lofty tower of the castle of St Angelo, he fell from a rampart and broke his leg; after his recovery he was subjected to a still more rigorous imprisonment in a loathsome dungeon; and it was only through the mediation of Francis I. that he obtained his liberation.

Repairing to France, he engaged assiduously in the exercise of his art, and he produced silver statues of some of the heathen gods and goddesses, which procured for the artist the greatest admiration, as well as a liberal pension, and other honours, from the king. But his good fortune again left him, and he returned to Italy, where he was taken into the service of Cosmo di Medici, grand duke of Tuscany; and at the desire of his patron he undertook to cast a statue of Perseus in bronze. In the execution of this great work he laboured with all his ingenuity; but when it was examined part of the right foot was found defective. When this superb production was exhibited to public view, it was beheld by all ranks with the highest admiration, and sonnets and epigrams, celebrating his praises, were addressed to the artist.

Cellini died in the year 1570; and as a mark of respect for his distinguished talents, his funeral obsequies were attended by all the members of the Florentine academy. As an artist he was almost unrivalled by his cotemporaries; and even at the present day his sculptures, casts, vases, and medals, are still admired and eagerly sought after. But his violent temper threw him into constant difficulties, and marred the success and good fortune to which his superior genius was entitled. As an author, Cellini holds a distinguished place. His treatise on the arts of jewellery, enamelling, and of making gold and silver vases, and silver statues larger than life, and on the method of casting statues in bronze, on the fabrication of colossal figures, and a discourse on design, is accounted a meritorious production. But the narrative of his own eventful life is one of the most curious and amusing works in any language. The latter was not published till the year 1730, and the English reader has an opportunity of perusing it in the translation of Dr Nugent, which appeared in 1771.

CELLULAR, in its general acceptation, denotes something which is composed of cells, as cellular substance, or membrane, which is employed in anatomical descriptions. See Anatomy.

CELOSIA, Cock's-comb, a genus of plants belonging to the Pentandria class.

CELSUS, a celebrated ancient physician, who flourished in the time of Augustus, and the author of eight books on medicine, which are not only distinguished by the purity and elegance of the Latinity, but are valuable documents relative to the medical practice of the times; and, as Boerhaave has remarked, may be regarded as an illustration of some of the obscure opinions of Hippocrates, the father of medicine. Celsus was also the author of various treatises on other subjects. His work on medicine was translated into English by Dr Grieve in 1756; and numerous editions, with learned commentaries, have appeared at different times.

CELSUS, an Epicurean philosopher, who lived in the second century, is chiefly known as the author of a work entitled the *True Word or Discourse*, which was written against the Christians. To this work an answer was drawn up by Origen, in whose writings, the original being lost, fragments only are preserved; and a summary of the arguments may be seen in the works of Doddridge, Leland, and Sherlock. It appears that Celsus was a man in some estimation among his cotemporaries, for Lucian has dedicated to him one of his works.

CELTS, an ancient people who are supposed to have inhabited the western parts of Europe. According to some authors of great learning, the Celts are to be considered as identically the same with the Scythians or Goths. But later enquirers have taken a different view of the subject, and have attempted to prove that they were quite a distinct people. In the discussion of this question, a good deal of the violence of controversy, and no small degree of irritation, arising perhaps from a kind of national feeling, have been introduced.

Those who maintain the distinction between the Goths and Celts, think, that they have established the following points by their arguments and illustrations. First, That the Syrians, about 1400 years before the Christian era, had proceeded from their original settlements, to the westward and northward, over a large portion of Europe; and that they were afterwards known in history under the name of Getæ, Goths, or Germans, or by the more general appellation of Syrians. Secondly, It appears from the earliest historical records, that the Celts occupied the regions in the vicinity of the Pyrenees about 500 years before the Christian era, and were expelled from their possessions by the Goths, or Germans, and driven into that part of Gaul which they held in the time of Cæsar's invasion. Thirdly, That the Welsh, some of the Irish tribes, and the inhabitants of the Highlands of Scotland, are the descendants of the ancient Celts: And, 4thly, A distinction is obviously made by the Greek and Roman writers between the Belgic and Celtic Gauls.

The distinguishing characteristics between the Celts and Goths, or Germans, are derived from their external appearance, from their religious belief, and sacred institutions,—from their political establishments, and from their language. See Pinkerton's *Enquiry into the History of Scotland*, and *Edinburgh Review*, *Vol. II.*

CEMENT is a substance which is employed for connecting together other bodies; and according to this definition, mortar, which unites the stones of a building, and retains them in their position, is included. The finer kinds of cement, which are employed for uniting broken glasses, earthen or china ware, are usually made of fine quicklime, well mixed with the white of an egg, and immediately applied. The different kinds of lutes for preventing the escape of vapours at the joinings of vessels, and of coatings for iron, earthen ware, and glass vessels, exposed to strong heat, in chemical processes, are sometimes brought under the same denomination. See *Mortar* under ARCHITECTURE, and *Lutes* under CHEMISTRY.

The word cement is also applied to those matters, which, being brought into contact with metallic substances, and subjected to a strong heat, produce very remarkable changes; as when iron, by means of charcoal is converted into steel, and copper by means of zinc becomes brass; and the process itself is called *cementation*.

CEMETERY, from the Greek word which signifies a place of repose, is a piece of ground set apart for the burial of the dead. It is curious to observe the different methods of disposing of the bodies of the dead in different nations, and in different periods of society; and although some nations commit the bodies of the dead to the waters, consign them to sequestered places, or reduce them to ashes by burning, yet it has been by far the most common custom to deposit them in the earth. The burial places of the Jews were caves, or grounds without their cities; and the Greeks and Romans who burnt their dead, deposited the urns in which their ashes were collected in retired places without the walls. The Turks and Chinese, of modern times, select similar places for their burying grounds. The barrows or cairns which are well known in different parts of Britain, are supposed to have been the burial places of persons of distinction who had fallen in battle.

The practice of burying in churches seems to have been first introduced in the fourth century of the Christian era; but it was strongly opposed, and expressly prohibited by various edicts. The porch of the church was at first employed as a cemetery; the bodies of the clergy were next permitted to repose within its walls; and, last of all, the same privilege was extended to persons of distinction among the laity.

CENSUS was a declaration made before the censors, by the subjects of the Roman empire, of the names, places of abode, possessions, families, slaves, and tenants; and the whole being accurately registered, served to shew the strength and resources of the nation. Some suppose that the census was held at Rome every five years, while, according to others, it was only observed at uncertain intervals. The same term is also employed in modern times to the method followed for ascertaining the population of a kingdom.

CENTAUR, in ancient mythology, is a kind of fabulous monster, half man and half horse. According to some, the centaurs were a body of shepherds who inhabited the Arcadian regions. According to others, some young men who had discovered the art of taming horses, undertook to free the mountains of Thessaly from a herd of wild bulls which ravaged the country; and having pursued them on horseback, received the appellation of centaurs. By another interpretation of the fable, the centaurs were a tribe of Lapithæ, who dwelt in a city contiguous to mount Pelion, and who first practiced the art of breaking horses.

CENTAUREA, GREATER CENTAURY, a genus of plants belonging to the Syngenesia class.

CENTER, in the construction of arches, is applied to the framing which supports the stones till the arch is completed. See ARCHITECTURE.

CEPHALANTHUS, BUTTON-WOOD, a genus of plants belonging to the Tetrandria class.

CEPHALIC denotes something belonging to the head, as cephalic medicines, which are remedies for disorders of the head; and cephalic vein, a vein of the arm, from which blood was taken, according to the theory of the ancients, for the purpose of removing complaints of the head.

CEPHALONIA, an island of the Ionian sea, which, with Zante, Corfu, Cerigo, Teaki, Leucadia, and Curzola, forms the republic of the seven islands. See SEVEN ISLANDS.

CEPHEUS, according to ancient mythology, was a king of Arcadia, and was rendered invincible in consequence of Minerva attaching one of the hairs of Medusa to his head.

CEPHEUS, is one of the constellations of the Northern Hemisphere.

CERAM, an island lying between Amboyna and Banda on the south, and the Molucca islands on the north, in the Indian ocean, and about 150 miles in length, and 60 miles in breadth.

CERAMBYX, a genus of insects belonging to the Coleoptera order. See ENTOMOLOGY.

CERASTIUM, MOUSE-EAR, a genus of plants belonging to the Decandria class.

CERATONIA, the CAROB TREE, or ST JOHN'S BREAD, a genus of plants belonging to the Polygamia class. The name, St John's Bread, is applied to the pods of this plant, from an opinion held by some that they were the locusts which St John used with honey in the wilderness, according to Scripture history.

CERAUNIA, a kind of stone frequently alluded to by ancient writers and naturalists, and supposed by some to be the work of art, and employed as a military weapon, or a cutting instrument. The word is derived from the Greek, signifying a thunderbolt; a vague notion seems to have prevailed, that they fell from the clouds during a thunder storm; and hence, modern naturalists have supposed that they are the same with meteoric stones, of whose descent from the clouds the most satisfactory evidence has been adduced.

CERBERUS, according to ancient mythology, was a three-headed dog, born of Typhon and Echidna, and appointed to guard the gates of hell. He is said to have fawned upon those who entered, but devoured all who attempted to return from the infernal abodes; he was conquered by Hercules, who dragged him to the earth, and during the struggle, it is said, the foam which dropped from the mouth of the monster produced the poisonous plant Aconite or Wolfsbane. Some suppose that Cerberus is the symbol of the earth, or of all devouring time, and that the three mouths denote the present, past, and future; but, according to Dr Bryant, Cerberus was the name of a place, and that it signified the temple of the sun. See Bryant's MYTHOLOGY.

CERCIS, JUDAS TREE, a genus of plants belonging to the Decandria class.

CEREALIA were feasts instituted in honour of Ceres, the goddess of corn, and were celebrated with great pomp and ceremony both by the Greeks and Romans. The same term is applied to those gramineous plants, the seeds of which are employed as food.

CERES, the goddess of corn in ancient mythology, was the daughter of Saturn and Ops, and the mother of Proserpine, who being stolen by Pluto, Ceres travelled over the world in search of her daughter, and having come to Celeus king of Eleusis, she undertook the charge of bringing up his infant son Triptolemus. To render him immortal, she fed him in the day time with divine milk, and in the night covered him with fire. Celeus, anxious to discover the manner in which his son was managed, concealed himself in the apartment, and seeing her place the infant under the embers, betrayed himself by a strong expression of his alarmed feelings. The curiosity of the father was punished with death; the son, as he grew up, was instructed in the art of cultivating corn and fruits; and being mounted on a chariot, drawn by winged dragons, he traversed the earth, to teach mankind the use of corn and fruits.

CERIGO, an island of the Mediterranean, celebrated under its ancient name *Cytherea*, as the birth-place of Venus, and is one of the Seven Islands of which the republic of that name is composed. See SEVEN ISLANDS.

CERINTHE, HONEYWORT, a genus of plants belonging to the Pentandria class.

CEROXYLON, WAX-PALM, a genus of plants belonging to the order of palms, and of which the species called *Andicola*, discovered by Humboldt, in the Andes, is the tallest vegetable production yet known. See BOTANY.

CERTIORARI, a term in the law of England, which denotes a writ issued from the court of Chancery or King's Bench, for removing the records of a cause from an inferior to a superior court, for the purpose of considering and determining the validity of appeals or indictments;—of bringing an indictment into the court of King's Bench, when any suspicion exists of partiality in the inferior court;—of pleading the king's pardon;—and of issuing processes of outlawry. Blackstone's *Commentaries*.

CERVANTES, MIGUEL DE SAAVEDRA, the celebrated author of *Don Quixote*, was a native of Spain, and was born at Alcala in New Castile, in the year 1547. He received his education at Madrid, but was more occupied in poetical compositions than in those studies which are requisite for the clerical or medical profession, for one of which he seems to have been destined by the wishes of his friends. Among his earliest productions were an elegy on queen Isabella, another poem, and some sonnets; but the little attention which they excited disgusted the author, and induced him to leave Spain and retire to Rome. The urgency of want compelled him to engage into the service of the cardinal Aquaviva in a menial capacity; but soon wearied of his situation, he entered the army as a common soldier, and served many years in this humble rank. In the battle of Lepanto, which was fought in 1571, he lost his left hand; and in 1574 he was doomed to slavery at Algiers, and experienced the most rigorous bondage from a barbarous master. He and his countrymen having made several attempts to escape from the harshness and cruelty of their condition, were at last betrayed, and called before the Dey, to receive, as they dreaded, the unmitigated sentence which might doom them to torture and death. To their surprise and astonishment a pardon was offered, on condition of discovering the author of the plan of escape. They all hesitated, when Cervantes came boldly forward, and declared himself to be the man. His daring intrepidity struck his savage masters, and rescued him from punishment; in succeeding attempts, in which he failed to regain his liberty, he was also pardoned; and even when he was detected in plots of a deeper nature, in stirring up insurrection and open rebellion, he was still fortunate in escaping the punishment which usually follows such violent schemes. He became, at last, the property of the Dey himself, and was shut up in close confinement.

The demand of 500 crowns of gold for his ransom, seems to indicate that he was regarded as a person of some rank. The sum was at last made up by the exertions of his parents and the benevolent contributions of others, and being transmitted to Algiers, Cervantes was restored, in 1580, to his native country. The commencement of his literary career is dated from this period, and his first work, after his return to Spain, was a pastoral entitled Galatea, which was well received by the public, and contributed to raise the reputation of the author. The famous *history of Don Quixote* was his next production, and is said to have had its origin in an incident which befel Cervantes himself while he was travelling in la Mancha. In a village of that province he was thrown into prison, either in consequence of having contracted debts or of a quarrel with the inhabitants, and while he remained in durance he composed the first part of the adventures of his renowned hero.

Cervantes was also the author of some comedies and novels; but they are comparatively little known, and quite thrown into the shade by the brilliancy of genius which adorns his Don Quixote. This work is intended as a satire on books of knight-errantry, which had so infatuated the greater part of mankind, and especially the Spanish nation. It was universally read, and painters, workers in tapestry, engravers, and sculptors, have exercised their ingenuity and talents in representing the history of Don Quixote. While Philip III. stood on a balcony of his palace at Madrid, he observed a student on the banks of the river Manzanares reading a book, and from time to time breaking off and striking his forehead with great enthusiasm. The king remarked to those near him, that the scholar was either mad or reading Don Quixote.

Few English readers are unacquainted with this work in their own language, and it has been translated into all the languages of Europe. Cervantes died in the year 1616; and with all the reputation which he acquired, it is melancholy to record, that he experienced, through the greater part of his life, all the hardships and miseries which accompany poverty.

CERUSS, or WHITE-LEAD, is a compound of oxid and carbonate of lead, which is usually prepared by exposing plates of the metal to the vapour of vinegar. It is used as an external application in medicine, and extensively employed in painting.

CERVUS, a genus of quadrupeds belonging to the order of Pecora, and including the deer, the antelope, and the goat. See MAMMALIA.

CERYX, a public crier or herald among the Greeks, corresponding to the *præco* of the Romans. Of these heralds two classes were established, the one of a civil nature, whose duty it was to call assemblies of the people, and to preserve the necessary silence and decorum in their public meetings. The other class was of a sacred character, and was regarded as a kind of priests, who proclaimed festivals, led the victims to the altar, and ordered all matters connected with public sacrifices and public games. This order of priesthood, called *ceryces*, was confined to a particular family, the descendants of Ceryx, the son of Eumolpus.

CESSIO BONORUM, a process in the law of Scotland, by which an insolvent person, who has been committed to prison by his creditors, may obtain his liberation by surrendering his whole real and personal estate. In most nations, in the early periods of society, bankrupts, or persons who were unable to discharge their debts, were treated with great harshness and severity, were regarded as degraded characters, and compelled to submit to the most humiliating ceremonies. In such cases the failure seems to have been ascribed to misconduct, and no discrimination was made between imprudence and misfortune. Among the Romans, by a law of the twelve tables, debtors were delivered over to their creditors, and might be kept in chains. By a subsequent enactment, their effects only were required to be given up; and, finally, the *cessio bonorum* introduced by Julius Cæsar, the operation of which was at first limited to Italy, was extended to all the Roman provinces before the time of the emperor Dioclesian. This law, which protected the person of the debtor from imprisonment, was adopted by those European nations who formed their systems of jurisprudence according to the Roman code.

By the law of Scotland, the debtor who claims the privilege of *cessio bonorum*, must have been at least one month in prison; and he is only entitled to it where no fraud exists. This process is always conducted before the court of Session, and the effect of it is to provide security against imprisonment; for the debt is not discharged, since any property acquired afterwards by the debtor, is liable to be attached by the creditor. This law requires also that persons liberated on a *cessio bonorum* shall submit to certain ignominious acts, as the wearing of a particular dress called the *dyvour's habit*. But the observance of this degrading distinction, if not formally abolished, has gone into desuetude. It is now always dispensed with. *Bell's Commentary on the Bankrupt Law.*

CESTRUM, BASTARD JESSAMINE, a genus of plants belonging to the Pentandria class.

CETE, in the Linnæan arrangement of animals, is the seventh order of the class Mammalia, and includes the whale tribe, which, in their mode of respiration and other functions, are connected with that class of animals under which they are described by Linnæus; but in their external form, locomotive powers, in their mode of life, and the element in which they reside, are allied to fishes. It will therefore be no great violation of arrangement, to detail the natural history of this tribe of animals in a separate division, under the tribe of fishes. See ICHTHYOLOGY.

CETOLOGY, denotes a treatise on the Cete or whales, which is the seventh order of the class Mammalia in the Linnæan arrangement. See ICHTHYOLOGY.

CEUTA, a sea-port town in the kingdom of Fez in Africa, which is situated on the southern coast of the Mediterranean, and nearly opposite to Gibraltar, from which it is not more than 15 miles distant. It has a commodious harbour for small vessels, is the see of a bishop who is suffragan of Lisbon, was taken from the Moors in the year 1409 by the Portuguese, continued annexed to Portugal till the revolution in 1640, when it fell under the dominion of Spain, and was finally ceded in 1688 to that country by the treaty of Lisbon. Succeeding attempts of the Moors to recover it failed, and finally left it in the hands of the Spaniards.

CEYLON, an island in the Indian ocean, at the southern extremity of Hindostan, from which it is separated by the gulf of Manaar, a narrow strait anciently called *Sinus Colchicus*, full of shoals and small islands, to which the natives have given the whimsical name of Adam's bridge, from the popular belief that our first parent, after his transgression and consequent loss of paradise in this island, passed over by it to the adjoining coast. Ceylon lies between 5° 40′, and 10° 30′ North Lat. and between 79° and 82° East Long. about 150 miles distant from Cape Comorin. It is reckoned 900 miles in circumference; its greatest length being nearly 300 miles, and its breadth varying from 40 to 150 miles. In shape it somewhat resembles a pear, the smaller or narrower extremity of which is towards the north, at the peninsula of Jafnapatam, hence vulgarly denominated by the Dutch *Hams-heel*, as Point Pedro, in its vicinity, is, with no less suitableness, styled *Hams-heel point*. In approaching from the sea, this island presents a green and fertile appearance, considerably more pleasing than most parts of the Malabar and Coromandel coasts; the one lying on the west, and the other on the east side of the vast peninsular continent, to which Ceylon seems to form an appendage. Its shores are flat and covered with verdant foliage, or display groves of cocoa-nut trees, alternating with rice fields, except on some parts of the eastern coast, which are bald and rocky. Steep and elevated mountains, clothed with thick forests, and full of almost impassable jungles, occupy the interior, and nearly divide the island into two parts, which differ materially from each other in climate and seasons. The general direction of these mountains is from north to south; some of them are of great height, and are the topic of several superstitious opinions in the mythology of the people. From the precipitous nature of the mountains, most of the rivers, with which Ceylon is so plentifully watered, are rapid and broken in the early part of their course. But they become uniform and tranquil towards the flat lands which skirt the central regions, and are unusually smooth, though rarely navigable at their outlet. Those of chief note are the Malivagonga and the Mulivaddy. Besides its rivers, Ceylon possesses a great number of lakes and canals communicating with them, some of which are of considerable extent, and render important benefits to the natives, as a ready mode of transporting goods, and a plentiful source of fresh water fish. The principal harbours are Trincomalee, and Point de Galle; but at certain seasons ships may moor safely in the roads of Columbo, and several smaller ports afford occasional shelter to coasting vessels.

The climate of this island, in general, is more temperate than that of India. The sea coast is more particularly well favoured in this respect, in consequence of the almost constant sea breezes, which moderate the heat, but which are scarcely known in the interior, from the impervious nature of the surrounding hills and forests. To the same obstructing cause is to be ascribed the little effect of the monsoons on the central regions, which consequently preserve an almost invariable state of temperature throughout the year. This is necessarily high and sultry in those parts. The monsoons nearly correspond with those of the adjoining continent, but are somewhat earlier on the western than on the eastern side. The seasons are more influenced by these monsoons than by the course of the sun; and hence, though it is situated to the north of the line, this island has its coolest season during the summer solstice, when the western monsoon prevails. Spring begins in October, and the hottest weather is experienced in the period from January to the beginning of April. In the wet season, which happens in March and April, the rain pours in torrents, and thunder and lightning are displayed in a manner quite unknown in European countries. From its situation with respect to the equator, the days and nights are nearly of the same length throughout the year, the greatest variation in their proportions not exceeding 15 minutes.

The soil of this island is sandy, with a small addition of clay. Marshy grounds are met with on the south-west parts, which are peculiarly fertile. Properly speaking, the sowing season is in July and August, and the harvest about February. But the inhabitants are little attentive to natural indications, and seem to expect equal success at all times. Rice is among the chief products cultivated, but, according to Mr Percival, is not raised in sufficient quantity for the demands of the people, who annually obtain large supplies from Bengal and other places on the continent. The defect, in that author's opinion, is entirely owing to mismanagement; and he is convinced, that, with proper attention, the necessity of importation might be readily obviated. Fruits of various kinds, peculiar to tropical countries, are abundant in Ceylon. Besides pine apples, pomegranates, citrons, oranges, &c. it boasts of the *mango*, one of the most delicious productions of India, two species of the bread-fruit tree, the tamarind, the sugar-pea a species of palm, the tea-plant, variety of spiceries, and the cinnamon tree in great quantities. Its flowers are not so numerous, nor so much attended to, according to the author named, but have an exceedingly rich odour, and sometimes are highly beautiful.

The mineralogy of Ceylon is varied, interesting, Ceylon. and valuable. Its sapphire, amethyst, and tourmaline are in great esteem, but its ruby, topaz, and diamond are inferior to those of Golconda and the Brasils. Carnelians and rock-crystal are in great plenty. The cat's-eye, a species of opal, is rarer, and bears a high price. Ores of lead, tin, and iron are met with in the interior, but are seldom wrought. Some mines of quicksilver have been found. The precious metals appear to be extremely scarce. The pearls, which form so great an article of commerce in this island are whiter than those of the gulf of Ormuz and the Arabian coasts.

In the zoology of Ceylon, the elephant holds the first rank, being produced in great numbers, and excelling in shape and appearance that of any other part of the world. The domestic animals are not numerous. The oxen are small, and not well-shaped. Horses and sheep do not thrive in the island. Buffaloes are found in great numbers, and are often employed to draw burthens. Hares, like those of Europe, are very plentiful. The wild hog frequents the forests. A small species of tyger, the tyger-cat, the leopard, hyena, and bear, are natives. Monkeys swarm, so do squirrels; and there is great variety of porcupines, racoons, and armadilloes. The birds are numerous. All our domestic poultry are found native. Snipes, parrots, pigeons, crows, wood-peckers, and a species of crane, are abundant. Kites and vultures are not frequent. Two species of peacock are indigenous. Among the reptile insect tribes may be enumerated the cobra de capello or hooded snake, whose bite is generally mortal, the cobra mamilla, a still more terrible creature, the rock snake, an immense species, sometimes extending to 30 feet in length, but free from poison, alligators of vast size, lizards, and chamæleons. A particular kind of leech is mentioned by Mr Percival as a formidable assailant on the traveller. It is quick in its motion, and readily contrives to fasten on a person's clothes, through which it is sure to find access to the skin. "On our way to Candy," says he, "in marching through the narrow paths among the woods, we were horribly annoyed by these vermin; for whenever any of us sat down, or even halted for a moment, we were sure to be immediately attacked by multitudes of them; and before we could get rid of them, our gloves and boots were filled with blood. This was attended with no small danger; for if a soldier were, from drunkenness or fatigue, to fall asleep on the ground, he must have perished by bleeding to death." Spiders, beetles, butterflies, and almost all the insects found in Europe, are met with in great numbers, besides other species peculiar to tropical countries. The white ant is a most destructive creature, and commits ravages both in the fields and dwelling-houses surpassing any idea of their operations that could be formed from our own species.

The population of Ceylon, which, according to Mr Cordiner, amounts to 1,500,000, consists of different races of mankind. The original inhabitants, or Ceylonese, till lately, were divided into two classes; those under the British government denominated Cingalese, and those of the interior, under their native princes, known by the name of Candians. These, though on the whole one stock, exhibited peculiarities to be attributed to the different circumstances in which they were placed. The recent acquisition of those parts of the island, which so long resisted the ambition and power of our countrymen, will probably soon obliterate their distinctions. Besides these people, and the Europeans settled in the country, are the Malays, and a numerous race known under the name of Portuguese, being the mixed progeny of those foreigners and the native females. Mr Percival has specified the distinguishing characteristics of all those inhabitants in a manner sufficiently interesting to warrant commendatory reference to his work.

This island, till lately, was considered as divided into two parts; the central regions, constituting the dominions of the king of Candy, and the maritime district surrounding that kingdom subject to Great Britain. The chief places worthy of notice in the former were, Candy, the capital, an ancient, but meanly-built town, near the centre of the island, almost entirely destitute of artificial defence, and containing no edifices deserving description; Badoula, a large town, with a decayed palace, to the south-east of Candy; Allout-neur, where the royal magazines of corn, &c. were preserved, 10 or 12 leagues north-east of the capital; and Digligy-neur, formerly a royal residence, a few leagues to the east of Candy. The principal places on the coast are, Columbo, the capital of the European settlements, a large, well-built, and populous town, situate in a fertile district, defended by a fort, and possessing a harbour, or rather road, in which vessels may safely anchor from December to April; Point de Galle, a populous trading town, 70 miles south of Columbo; Jafnapatam, a considerable town, chiefly inhabited by manufacturers, near the northern extremity of the island; and Trincomalee, a walled town of large extent, but thinly inhabited, lying on the east of the island, at the entrance of an excellent bay.

The principal commodities exported from Ceylon are, pepper, cinnamon, betel-leaf, cocoa-nuts, and oil; honey, and wax; cardamoms, and other aromatic spiceries; coral, ivory, and fruit. Coya-rope, or cordage, is manufactured in large quantities near Columbo, and sent to the British vessels frequenting the Indian sea.

The revenues are supposed to be much improved since the island came into the hands of the English, but are perhaps scarcely as yet commensurate to the expence of government and protection. No long time, surely, can elapse before the benefits of its entire subjection can be realized.

Little is known of the history of this singular island before the arrival of the Portuguese under Almeyda in 1505. The natives, long harassed by the attacks of the Arabs, readily consented to pay tribute to these Europeans, in consideration of being assisted against their invaders. At this period, some savages, called Bedas, occupied the woody regions; the rest of the island was possessed by the Cingalese, who do not seem to have differed much from their descendants. Not content with a friendly alliance, the Portuguese endeavoured to form a settlement in the island, in which they succeeded, after a long and severe struggle, under Albuquerque, the successor of Almeyda. The sea-coast fell into their hands, and the interior alone remained to the original possessors. Avarice was the ruling principle with these new masters; and hence the rights and interests of the natives were entirely overlooked, or unjustly violated. Bigotry was the next agent in the policy of the Portuguese, and gave, if possible, greater offence. Thus, dissatisfaction and war continued between the two people for nearly a century, when the Dutch, having thrown off the yoke of Spain, urged their way to the east, and reached this island. They were favourably received by the oppressed natives, and being assisted by them, at last overpowered the Portuguese, who yielded the dominion in 1656. But the conduct of these successful allies soon offended the natives almost as much as that of their predecessors; and hostilities of a long duration took place between them, in which, on the whole, the Dutch were the greatest sufferers, though the Ceylonese were eventually driven to the fastnesses of the interior, where alone they could preserve their independence. A treaty was at last concluded between the two parties in 1766, which inflicted several hardships on the king of Candy, but left him at least the name and somewhat of the appearance of royalty.

The American war brought the English to this island. But their arms, though victorious, were not rewarded with permanent success, till the contest with revolutionary France and her allies induced a new and powerful expedition against it, under general Stewart, in 1796. Since that period various transactions have occurred between our countrymen and the Candians. A treaty of alliance and commerce was projected in 1800, but failed. Our troops took possession of their country and capital in 1803; but being unable to maintain their conquests were forced to capitulate, on condition of liberty to return to Columbo. In place of this being fulfilled, however, they were treacherously put to death with circumstances of the most savage cruelty. An expedition of 3000 men, fitted out in 1815, under the command of General Brownrigg, in concert with the inhabitants, who had become weary of their tyrannical and blood-thirsty monarch, entered his capital in triumph, and in a few days afterwards captured the monster himself, and deprived him of all power. The people delighted at their deliverance, readily transferred their allegiance to their rescuers, and appear already to experience the blessings of a British government.

CHÆRONEA, a village of Bœotia in Greece, which is celebrated as the birth place of Plutarch, and is still more famous on account of the signal disaster which the confederated Greeks experienced when they were defeated by Philip king of Macedon.

CHÆROPHYLLUM, CHERVIL, a genus of plants belonging to the Pentandria class, and the natural order of umbellated plants.

CHÆTODON, a genus of fishes. See ICHTHYOLOGY.

CHAINWORK, a species of cloth manufacture, in which the threads are linked or united together somewhat in the manner of a chain, as in the case of hosiery and various kinds of fancy weaving, both of silk and cotton fabrics. See CLOTH MANUFACTURE and HOSIERY.

CHALCEDONY, or CALCEDONY, a mineral substance, which, on account of the fine polish of which it is susceptible, is employed in jewellery. See *Chalcedony* under GEOLOGY.

CHALK, a well known mineral substance, which abounds in England and some other countries, but is never met with as a natural production in Scotland. See GEOLOGY.

CHALLENGE, an invitation or summons sent by one person to provoke another to fight a duel. A challenge of this description either verbal or written, or even the bearer of such a challenge, is punishable by fine and imprisonment, on indictment, or information.

CHALLENGE, according to the law of England, is an exception made to jurors either in civil or criminal cases.

In civil cases, challenges are of two kinds, either to the array or to the poll. In the first case, the challenge extends to the whole jury on account of partiality, as in the case of nominating the jury under the direction or influence of either party. Challenges to the poll, are exceptions to particular individuals who are nominated to sit on the jury. Similar exceptions, and on similar grounds, are permitted in criminal cases. Blackstone's *Commentaries*.

CHALONS SUR MARNE, the capital of the department of Marne in France, includes a population of more than 11,000, and has considerable manufactories of woollen stuffs.

CHALONS SUR SAONE, a town of the department of Saone and Loire, contains 12,000 inhabitants, has a considerable trade in grain, wines, and iron, and retains some celebrity on account of the ruins of Roman edifices which are yet visible.

CHAMÆLEON, a species of Lacerta, which is remarkable for its powers of changing colours. See *Lacerta* under ERPETOLOGY.

CHAMÆROPS, the FAN PALM, a genus of plants which belongs to the order of palms. See BOTANY.

CHAMBERLAIN, one of the great officers of state in Britain, who is reckoned the sixth in rank, holds his office by hereditary right, and is charged with the direction of the ceremonies observed at coronations and other solemn occasions. The lord-chamberlain of the royal household has the superintendence of all officers belonging to the king's chamber, as artificers, serjeants at arms, chaplains, and physicians, as well as of the wardrobe, and of all matters connected with theatrical exhibitions, and particularly the licensing of plays for representation.

CHAMBERS, EPHRAIM, the author of the Cyclopædia, or Dictionary of Arts and Sciences, which is distinguished by his name, was a native of Westmoreland in England, and was apprentice to Mr Senex, the globe-maker, in London, a business which requires or leads to some practical knowledge of geography and astronomy. During this time, it is said, he formed the design of the Cyclopædia, and for the purpose of executing that laborious undertaking, he resigned his mechanical employments, and retired to apartments in Gray's inn, which was chiefly his place of residence during the rest of his life. The first edition of the Cyclopædia, which was published by subscription, appeared in 1728 in two vols. *folio.* A second edition was called for in 1738, and a third followed in the succeeding year.

The literary labours of Mr Chambers were not solely confined to the Dictionary. He was a contributor to the *Literary Magazine*, which commenced in 1735; and in conjunction with Dr Martyn, professor of botany at Cambridge, he presented to the world an abridged translation of the Memoirs of the Academy of Sciences at Paris, on the subject of natural philosophy. This work, amounting to 5 vols. *octavo*, appeared in 1742.

The severe studies in which Mr Chambers had been engaged affected his health, and obliged him to retire occasionally to the vicinity of the metropolis, to enjoy the benefit of a purer air. A visit to the milder climate of the south of France did not contribute to his recovery; and soon after his return to England he died, and was buried at Westminster abbey, where an inscription in elegant Latin, said to have been written by himself, alludes to the business of his life, and marks the period of his death in 1740.

Two other editions of the Cyclopædia were published after the author's death; a supplement consisting of two volumes was afterwards compiled; in the year 1778 a new edition, in which the whole was incorporated into one alphabet, was completed in four vols. *folio*, under the superintendence of Dr Rees; and the same learned author has now (1818) nearly finished the most extensive edition of that work, probably not less than 40 vols. 4to, which has yet appeared.

CHAMBERY, a town of Savoy in Italy, is finely situated in a valley encompassed with mountains, includes some elegant houses and magnificent public buildings, and reckons about 12,000 inhabitants, who are engaged in the manufactures of stockings, silk thread, and leather, in the working of marble, and in the distillation of liqueurs, which are greatly esteemed.

CHAMOIS, or CHAMOIS GOAT. See *Cervus* under MAMMALIA.

CHAMOUNI, an elevated valley of the Alps, which lies north from mount Blanc, and south-east from the lake of Geneva, is about 18 miles in length from north-east to south-west, and is not more than a mile and a half at its greatest breadth. The vale of Chamouni is more than 3,000 feet above the level of the sea. For six months of the year, from November to May, it is covered with snow, and in some places of great thickness; but the short summer is warm and agreeable. The river Arve flows through its centre, and in its course is joined by some mountainous torrents.

The population exceeds 3000. The cultivated crops are oats, barley, beans, and flax; but the dairy husbandry is an object of greater attention, and a good deal of butter and cheese is produced. The rearing of bees is also much attended to, and the honey thus obtained, which is in high estimation for its delicious taste and rich flavour, is a source of considerable profit.

Many of the inhabitants of Chamouni are engaged in the hazardous occupation of hunting the Chamois goat, an animal which frequents the steepest and most inaccessible rocks, and in the search for rock-crystal, which is found in the cavities of the precipitate cliffs of the Alpine region. The numerous travellers who frequent this valley for the purpose of visiting mount Blanc, avail themselves of the proffered services of the inhabitants, who are found to be expert and faithful guides in that arduous undertaking. The celebrated naturalist Sanssure has drawn an animated picture of the inhabitants of this valley, and of their occupations, manners, and mode of life.

CHAMPAGNE, a province of France; according to its former topographical divisions, is about 160 miles long and 112 miles broad; has for its boundaries on the north and west, Hainault, Luxembourg, and the isle of France; and on the east and south, Lorraine, Franche Compte, and Burgundy, and is watered by the Meuse, the Seine, the Marne, the Aube, and the Aine. It is now divided into several departments.

CHAMPION, a person who engages to fight in single combat in the cause of another, and sometimes in his own cause. According to the barbarous practice of rude nations, the method of settling disputes by single combat between the parties concerned was common; and the form of judicial combat was arranged and established by legislative enactments, in times in which it might have been expected that such absurd and unjust proceedings would not have appeared. It is not a little singular, that the laws of England with regard to this kind of trial, or *wager of battel*, stands at this day unrepealed.

The female sex, infirm persons, and those who were advanced in life, or were of the clerical profession, were permitted to employ a substitute, or a champion, to fight in their cause; but afterwards the champion appeared in all cases, and at last became a necessary part of a great man's establishment.

In this capacity the champion of the king appears at the coronation, and when the king is at dinner, he rides into Westminster hall, fully armed, and by the proclamation of a herald, declares, that if any man shall deny the king's title to the crown, he is there ready to defend it in single combat. This office is hereditary; and in a competition in the time of Richard II. it was adjudged to Sir John Dymocke, in whose family, holding a manor in Lincolnshire, it has ever since remained. Sir Edward Dymocke discharged this duty at the coronation of Charles II. and the same ceremony was performed by a person of that name at the coronation of George III.

CHANCE, a term which is applied to those events of which the immediate cause is not known. Those things are ascribed to chance which are not necessarily produced as the natural effects of any proper cause; but it must be observed, that effects are attributed to chance which really have a necessary and determinate cause. In strict language, therefore, when a thing is said to happen by chance, nothing more is meant than that the cause is unknown.

The doctrine of chances constitutes a curious subject of mathematical investigation, which is directed to ascertain the probability of the occurrence of such events as cannot be predicted with certainty from want of knowledge of their true causes. The chances of play, or the probable result of those circumstances which are not subject to the skill or management of the players, belong to this investigation. Such, for example, are all games which depend on the shuffling of cards or the throwing of dice, and such too is the nature of lotteries. But the most important application of the results of this investigation is in the determination of questions relative to the probable duration of human life. Annuities depending on lives, and life-insurances are regulated by the doctrines established by such enquiries. See De Moivre's *Doctrine of Chances*, and Simpson *on the Nature and Laws of Chance*.

CHANCE-MEDLEY, is a term in the English criminal law, which denotes the lowest kind of homicide to which any punishment is adjudged; and consists in causing the death of a man, upon occasion of a sudden quarrel, and in self-defence. But the self-defence must have been had recourse to after other means of self-preservation have failed, otherwise the offence will be considered man-slaughter. In the case of homicide by misadventure, the act of killing is intentionally necessary for self-preservation; but in chance-medley no intention of committing injury exists,—as when the head of a hatchet, with which a man is employed at work, flies off and kills a spectator. In both cases the law presumes that the occasion of killing might have been avoided, in the one by a greater care, and in the other by abstaining from the quarrel which terminated so fatally.

CHANCELLOR is said to have been at first the chief notary, or scribe, under the emperors. According to some, the name is derived from the Latin word signifying a *lattice*, behind which he sat, to avoid being crowded by the people; and, according to others, from *cancellare*, to cancel. This officer was afterwards invested with judicial powers; and when the modern kingdoms of Europe were established upon the ruins of the empire, almost every state preserved its chancellor, with different jurisdictions and dignities, according to the nature of their civil constitutions. When the use of seals was adopted in solemn deeds, the custody of the king's great seal was intrusted to the chancellor.

The Lord Chancellor of Great Britain possesses the highest judicial authority in the kingdom; he is created by the mere delivery of the king's great seal; is a privy-counsellor by his office, and, by prescription, the prolocutor or speaker of the house of Lords. All the justices of the peace in the kingdom are appointed by him. In right of the king he is the visitor of all hospitals and colleges on the royal foundation; he is the patron of all the king's livings under the value of L.20 *per annum*; is the general guardian of all infants, idiots, and lunatics, and has the superintendence of all charitable uses. In his judicial capacity in the court of Chancery, he exercises a very extensive jurisdiction. He takes precedence of all temporal lords, except those of the royal family, and of all the spiritual lords except the archbishop of Canterbury.

CHANCERY, the highest court of justice in the kingdom next to Parliament, and deriving its name from the Lord Chancellor, who presides in it. The jurisdiction of the court of Chancery is either ordinary, or a court of common law, or extraordinary, or a court of equity. The *ordinary* legal court holds pleas of recognisances acknowledged in the chancery, writs of *scire facias*, for repeal of letters patent, writs of partition, as well as of all personal actions, by or against any officer of the court. Sometimes a *supersedeas* or writ of privilege, is granted to discharge a person out of prison; one from hence may have *habeas corpus* prohibition, &c. in the vacation: and here a *subpœna* may be had to force witnesses to appear in other courts, when they have no power to call them. But if the prosecution of causes of trial by jury be required, the Lord Chancellor delivers the record into the King's Bench; and after trial it is remanded into the Chancery, where judgement is pronounced. In this court also is kept the *officina justitiæ*, out of which all original writs that pass under the great seal, all commissions of charitable uses, bankruptcy, lunacy, and the like, are issued. The writs relating to the business of the subject were originally kept in a hamper, and those connected with the crown were preserved in a small bag, and hence the distinction of the *Hanaper Office*, and the *Petty-Bag Office*.

The *extraordinary* court proceeds according to the rules of equity, and considering the intention rather than the words, moderates the rigour of the common law. It gives relief for and against infants during their minority; for or against married women; takes cognizance of frauds and deceits for which there is no redress at common law; of all breaches of trust and confidence; of the confirmation of titles to land where any defect exists; of money or lands given to charitable uses; and, in general, of all matters which cannot be settled by the rules of common law. Blackstone's *Commentaries*.

CHAPEL, derived from the Latin, *Capella*, is a place of divine worship. In the early periods of the French history it was usual for the kings of France, when they were engaged in war, to carry into the field the hat of St Martin, which was esteemed a precious relic; the tent in which it was kept was called *capella*, and the priests who had the charge of it were called *capellani*; and the same word *capella* was afterwards applied to private oratories or chapels.

Several kinds of chapels are known in Britain as *parochial* chapels, which differ little from parish churches; they are generally small, and the inhabitants within the district few; chapels which form part of churches, and were erected by persons of distinction as burying places for their families; chapels-of-ease, erected in large parishes where the people cannot be conveniently accommodated in the parish church; free chapels, which were founded by kings of England, and are free from episcopal jurisdiction; they are only to be visited by the founder and his successors, which is done by the Lord Chancellor; chapels in the universities, which belong to particular colleges; and domestic chapels, erected by private individuals for the performance of religious duties in their own families.

CHAPLAIN, denotes a person who discharges the duty of a chaplain, or is applied to a clergyman who attends in the house of a prince or a person of rank for the purpose of performing divine service in the private chapel of the family. In England the king has 48 chaplains, four of which attend monthly, preach in the chapel, read the service to the royal family, and to the king in his private oratory. The king has six chaplains in Scotland, with a salary of L.50 each; and three of them having, in addition, the deanry of the chapel-royal divided among them, increases their appointment to L.100 each. The only duty required of them is to say prayers at the election of the representatives of the peers in parliament.

According to a statute of Henry VIII. the persons who have the power of retaining chaplains, and the number which they are allowed to qualify, are specified. An archbishop may retain eight; a duke or bishop six; a marquis or earl five; a viscount four; a duchess, marchioness, countess, baroness, the treasurer and comptroller of the king's house, clerk of the closet, the king's secretary, dean of the chapel, almoner, and master of the rolls, each of them two; chief-justice of the king's Bench and warden of the cinque-ports, each one. All these chaplains may purchase a licence or dispensation, and take two benefices with cure of souls.

CHAPTER, a society or community of clergymen, belonging to cathedrals or collegiate churches, first assumed this appellation in the eighth century, and in a cathedral formed the council of the bishop, and during the vacancy of the see held the jurisdiction of the diocese. In the earlier ages the bishop was the head of the chapter, but abbots, deans, provosts, and treasurers were afterwards preferred to this distinction. The power of electing bishops was taken from the dean and chapters by Henry VIII. and vested in the crown. The same monarch expelled the monks from the cathedrals, and placed secular canons in their stead. Those who were subjected to these regulations were called deans and chapters of the new foundation; among which are Canterbury, Winchester, Ely, and Carlisle.

CHARACTER, from the Greek word, which signifies to cut or engrave, is, in its general meaning, a mark or figure denoting something which is not directly represented. Characters are of different descriptions, as literal, or those which represent the letters of the alphabet, numeral, which are used to express numbers, and are either letters or figures, and abbreviations, which are employed in various arts. See LANGUAGE.

CHARADE, a kind of literary composition, which, it is said, bears the name of the inventor. The subject is a word of two syllables, and each of these constitutes a distinct word. In the construction of the charade these two syllables are concealed in a kind of enigmatical description, first separately, and then together. This amusement, if not useful, is innocent, and affords exercise to ingenuity. The following examples will be a sufficient illustration of the nature and construction of the charade.

My *first* is ploughed for various reasons, and grain is frequently buried in it to little purpose. My *second* is neither riches nor honours; yet the former would generally be given for it, and the latter is often tasteless without it. My *whole* applies equally to spring, summer, autumn, and winter; and both fish and flesh, praise and censure, mirth and melancholy, are the better for being in it.—*Sea-son.*

My *first* is equally friendly to the thief and the lover, the toper and the student. My *second* is light's opposite; yet they are frequently seen hand in hand; and their union, if judicious, gives much pleasure. My *whole* is tempting to the touch, grateful to the sight, fatal to the taste. *Night-shade.*

My *first* is called bad or good,
May pleasure or offend ye;
My *second*, in a thirsty mood,
May very much befriend ye.
My *whole*, though styled a cruel word,
May yet appear a kind one;
It often may with joy be heard,
With tears may often blind one.—*Fare-well.*

CHARADRIUS, a genus of birds, which includes the plover and dotterel. See ORNITHOLOGY.

CHARCOAL, a kind of artificial fuel, which is prepared by a smothered combustion, from wood or mineral coal, although the latter is often distinguished by the name of coak. Charcoal, which possesses many remarkable chemical properties, is generally prepared from small pieces of wood, and white resinous wood is unsuitable for this purpose. Different woods, too, it may be observed, afford very different proportions of charcoal. The great consumpt is in the iron-works, or in other cases where a strong heat without smoke is required.

Wood is charred, or converted into charcoal, in the following manner. It is first cut into proper lengths, and piled up in heaps, the stacks are constructed in three different ways; according to the first method a convenient spot of ground about 12 or 15 feet in diameter is levelled, and in the centre of this area a large billet of wood split across at one end and pointed at the other, is fixed by its pointed extremity in the earth, and two pieces of wood are inserted through the clefts of the other end, forming four right angles; against these cross pieces four other billets of wood are placed, one end on the ground and the other leaning against the angles. Straight billets are then laid on the ground to form a floor, each of these billets being the radius of the circular area. A quantity of brushwood is then strewed on the floor to fill up the interstices. And to keep the billets in the same position in which they are first arranged, pegs are driven into the ground in the circumference of the circle, about a foot distant from each other; on this a floor or stage is built with billets set upon one end and slightly inclining towards the centre. On the top of these billets another floor is laid in a horizontal direction, but of shorter billets; so that the whole when finished may be of a conical form.

A second method of building stacks for charring wood, is to erect a long pole in the centre of the area, and several small billets are ranged around the pole on their ends, while the interstices between the billets and pole are filled with dry brush wood; a floor is then laid, and on that a stage in a reclining position, and on the stage a second floor in the same way as in the first method of forming the stack. But

Charente.

in the lower floor, a billet larger and longer than the rest extends from the central pole to some distance beyond the circumference of the circle.

By a third method of constructing the stack, a chimney or opening, of a square form, is made with billets in the centre from the bottom to the top, and round them floors, on inclined stages, are raised in the same way as in the former stacks, excepting that the base of the stack in this mode of construction is square instead of being circular, and when it is completed the whole stack is of a pyramidal form.

In whatever way the stack is constructed, it is covered over with a coating of turf, and the surface is plastered with a compound of earth and charcoal dust well mixed together.

If the stack be constructed according to the first method, the central billet in the upper stage is drawn out, and some pieces of dry wood are placed in the chimney or vacant space, and set fire to. In the second method of construction, both the central pole and the large horizontal billet are drawn out, and the vacant space which was occupied by the latter, is filled with pieces of dry wood, to which the fire is applied at the base of the stack. In the third method of construction, the chimney or square opening is filled with dry pieces of wood, and the fire is applied at the top of the pyramid.

Great care is requisite in the management of the fire. When the flame begins to rise to some height above the chimney, the opening should be covered with turf, but not so close as to prevent the smoke from passing out; and in the course of the operation, if a thick mass of smoke appear to issue from any part of the pile, the opening must be covered up with a mixture of earth and charcoal dust. To ensure the equal combustion of the whole stack, it is necessary that the workman make openings in one part, and close them in another. In this way the fire is kept up till the charring process be completed, which for dry wood requires about two days and a half, and for green wood not less than three days.

When the charcoal is sufficiently burnt, which is indicated by the cessation of the flame, and the appearance of the smoke, the whole is covered up to exclude the air and prevent the further progress of the combustion; the fire then goes out, and in the course of a few days the stack may be taken down. Some precautions are necessary to avoid the danger which may arise from the sudden explosion of the carburetted hydrogen gas, which is copiously evolved during the process. Part of the covering of the stack is usually thrown off during these explosions.

Charcoal is chiefly employed as fuel; it forms one of the constituent parts of gun powder; is used as a tooth powder, and to polish brass and copper; is the bases of black paints and varnishes, and is applied for clarifying liquors. For its peculiar properties, see CHEMISTRY.

CHARENTE, a department in France, comprehending the ancient province of Angoumois, with part of Saintonge and Limosin. It lies to the south of Vendee, is about 30 French leagues in length, and 25 in breadth, contains 300 square leagues, is divided into five circles, viz. Ruffec, Confolens, Angoulesme, Barbezieux, and Cognac, and has a population of more than 300,000 souls. The name is derived from the river Charente, which has its origin in Limosin, and runs by Angoulesme and Saintes into the bay of Biscay, opposite to the island of Oleron. Much of this department is either barren or covered with woods, but part of it is tolerably productive of grain, and about a third of it allows the successful cultivation of the vine. It is famous for its manufactures of paper, and has several mines of iron ore and antimony. Besides the Charente, which is noted for its winding course, this department is watered by the Louvre and the Boutonne, both of which run into that river, the former at Angoulesme, and the latter two leagues to the east of Rochefort.

Angoulesme, the capital of the department, is an ancient city, seated on a mountain surrounded with rocks, but indifferently defended by a castle and the remains of a wall; it is an episcopal see, containing twelve parishes and two abbeys. The inhabitants are computed at 14,000, and its chief manufactures are coarse cloth and paper. It lies 23 leagues south-east of Rochefort. The ancient name of this town was Iculisma, or Iculisna, but it is little noticed in history.

Cognac, famed for its brandy, vulgarly called Coniac, is only a small town, containing about 3000 inhabitants, seven leagues westward of Angoulesme. It stands in a fruitful and agreeable country, watered by the Charente, and is defended by a castle. Here Francis I. was born, and several councils were held.

Barbezieux, about five leagues south-east of Cognac, and 45 miles north-east of Bourdeaux, contains nearly 2000 inhabitants, and is noted for its mineral spring and a manufacture of linen cloth. It is pleasantly situate in a picturesque country.

Confolens and Ruffec, are small towns in the northern extremities of the department.

Jarnac is a market town on the Charente, about 20 miles west of Angoulesme, on the road to Cognac. The protestants were defeated by the duke of Anjou, afterward Henry III. in 1569, near this place.

CHARENTE, INFERIEURE, or Lower, a department in France, comprising part of the province of Saintonge and Aunis. It is about 40 French leagues long, and more than 20 broad, contains 366 square leagues of territory, and upwards of 400,000 inhabitants. It is a maritime district, lying between Charente and the bay of Biscay, and is divided into six circles, viz. Rochelle, Rochefort, St Jean d'Angely, Saintes, Jonzac, and Marennes, besides the islands of Re and Oleron. The soil of this department is generally good, and yields grain and fruits in abundance, but that part which borders on the ocean is considered unhealthy. It has several mines, and some medicinal springs. Its manufactures and articles of trade are similar to those of Charente.

Saintes, the capital, anciently called Mediolanum Sanctorum, 14 leagues west of Angoulesme, also on the Charente, is a badly built town, containing 10,000 inhabitants. It has a noble cathedral, and is rich in monuments of ancient grandeur. Of these the most remarkable are an aquæduct, an amphitheatre, and a triumphal arch.

Rochelle, a fortified sea-port, containing nearly 20,000 inhabitants, is more than 200 miles south-west of Paris. It is neatly built, but stands in a marshy situation, has a good harbour, tolerably well defended, and carries on a considerable trade in wine, brandy, paper, and linen. It is a bishop's see, and has an academy of sciences. Rochelle was the chief town possessed by the reformed in the 16th century, and was strongly fortified by them. But it was taken in 1628, after a tedious and difficult siege. Its reduction proved the death-blow to their cause in France, as there then remained no security against the power and malice of their opponents. Its fortifications, which had been destroyed, were afterwards repaired by the celebrated Vauban. The old name of this city was Portus Santonium.

Rochefort, a sea-port, 15 miles from the mouth of the Charente, and 18 south south-east of Rochelle, is strongly fortified, possesses a military arsenal and magazines, and contains 15,000 inhabitants. It was at one time reckoned unhealthy, but this remark does not apply to it since the draining of the marshy lands in its vicinity. Rochefort is quite a modern town, having been founded by Louis XIV. about the middle of the 17th century.

St Jean d'Angely, 32 miles south east of Rochelle, was once an important town, but has dwindled in recent times, and now scarcely contains 6,000 inhabitants. It is seated on the Boutonne, and is famous for its brandy. A Benedictine abbey was founded here in the 8th century. This is one of the places formerly in the hands of the protestants, who contributed greatly to its prosperity. Its fortifications were demolished in 1621.

Jonzac, is a small place to the west of Barbezieux.

Marennes, is a sea-port, containing about 5,000 inhabitants, situate in a marshy tract opposite the isle of Oleron. It is noted for a particular species of oyster, and trades pretty extensively in grain and salt.

Marans, a market town, 12 miles north-east of Rochelle, has a good trade in similar articles.

Pons, an inland town, 10 miles south-east of Saintes, is well built, and contains upwards of 4000 inhabitants. It is famed for a mineral spring.

Talmont, a market town on the coast, 20 miles south-west of Saintes, has a harbour.

At *Tailleborg* on the banks of the Charente, about 8 miles north of Saintes, the English under Henry III. sustained a smart defeat in 1242. On this occasion the policy of prince Richard, brother of Henry, saved his countrymen from farther loss, by amusing the French monarch with proposals for a truce, till they made good their retreat. About four thousand English were taken prisoners, and Henry himself owed his safety to the speed of his horse.

The island of *Re* or *Rhe*, which lies near the coast of this department, opposite Rochelle, is about 16 miles long and four broad. It contains about 18,000 inhabitants, and carries on a brisk trade in wine, brandy, and a liquor called aniseed water.

St Martin, its capital, is pretty well fortified, and has a tolerable good harbour.

Oleron, opposite the mouth of the Charente, is a populous and fruitful island, 14 miles long and five broad. Its chief products are grain and wine. It contains five or six towns and several villages. Part of the island is fortified by art, and most of the remainder is protected by the ruggedness and abrupt character of the coast. Oleron at one period belonged to the crown of England, and gave name to the famous code of laws promulgated by Richard I. on his return from captivity in Germany, the greater part of which still regulates the maritime affairs of Europe. These laws, forming 47 heads or chapters, are printed in Godolphin's *View of Admiralty Jurisdictions.* See Anderson's *History of Commerce*, vol. i. page 179. The ancient name of this island was Uliarius.

The small island of *Aix*, lies between Oleron and the continent, and has a fort which protects the entrance into the Charente. It is 12 miles north-west of Rochefort.

CHARLESTOWN, the capital of the state of South Carolina in America. See CAROLINA, SOUTH.

CHART, a hydrographical map, or a projection of some part of the earth's surface, particularly constructed for the use of mariners. See GEOGRAPHY.

CHARTA, in its original meaning, denotes a kind of paper made of the Egyptian Papyrus or Biblus, but signifies also a charter or deed in writing. Magna Charta, or the great charter, is so called from being the great charter of the liberties of England, and the foundation of her laws and privileges. This charter may be said to derive its origin from Edward the confessor, who granted several privileges to the church and state. These privileges were confirmed by Henry the First, and they were farther confirmed or re-enacted by Henry II. and King John, in whose reign the present Magna Charta was obtained.

CHARTRES, a city of the department of the Eure and Loire in France, stands on the river Eure, and is remarkable for the spires of one of the churches, one of which is admired for its magnitude, and the other for the beauty of its ornaments. The population is stated at 15,000, and a great deal of woollen stuffs are manufactured in the neighbouring villages.

CHARYBDIS, a whirlpool in the straits of Messina, between Naples and Sicily, and opposite to Scylla, a rock on the coast of Italy, and frequently alluded to by the ancients. The dangers of the navigation, arising from the whirlpool and the rock, have given rise to the proverb, Avoiding Charybdis he falls on Scylla; which is expressive of the risk of encountering one evil by shunning another.

CHATHAM, a town of Kent in England. See KENT.

CHATTERTON, THOMAS, an English poet, who acquired considerable notoriety by a species of literary fraud, was born at Bristol in the year 1750, and was the posthumous son of the master of a free school in that city. It is said he made slow progress in acquiring even a knowledge of the letters of the alphabet, till he met with the illuminated capitals of an old manuscript. In his 8th year he began to attend a charity school, where he was instructed in reading, writing, and arithmetic. Soon after this period he discovered a strong desire for reading, and before he was 12 years of age it is said that he had perused 70 volumes, chiefly on subjects of history and divinity. At this time, too, he had begun to make verses, and his deportment was distinguished by unusual gravity, and even some tincture of melancholy. In his 15th

Chatterton. year he was bound apprentice to a scrivener, and he employed his leisure hours in transcribing old English glossaries and in studying heraldry.

The opening of a new bridge at Bristol in 1768, forms a remarkable era in the life of Chatterton, for at that time a paper appeared in a Bristol journal, containing a description of the friars first passing the old bridge; and this paper was professed to be extracted from an old manuscript. This production, which excited great attention, was traced to Chatterton, and threats were used to induce him to declare from what source he obtained it. Evasive or contradictory explanations were given; and it was at last asserted, that the paper was found in a chest in Redcliffe church in Bristol. This church was erected or rebuilt in the 15th century, and six or seven chests had been deposited in it. In the year 1727, one of these chests was broken open by authority, the keys being lost, and some title-deeds were removed, but some manuscripts were left. The father of Chatterton, who had been at one period a singer in the cathedral, carried away many of the parchments, and among them the young man pretended that he had discovered the poems which he presented to the public under the name of *Rowley*, a priest of the 15th century. About this time Chatterton was known as a contributor to the Town and Country Magazine, both in prose and poetical compositions; and while he succeeded in imposing on the credulity of some the productions which were brought forward as ancient poems, the knowledge of his talents convinced others that they were to be ascribed to himself as the real author.

The flattering reception which these productions, whether they are to be considered ancient or modern, obtained in his native city, induced him to address a letter to the Honourable Horace Walpole, accompanied with specimens of the poetry of Rowley, and offering to furnish him with some account of ancient painters of eminence at Bristol. The poems were pronounced to be forgeries by those who examined them; and an attempt of Chatterton to renew the correspondence with Walpole failed. The neglect which he experienced from Walpole, whether it arose from the impression of imposition relative to the poems, or from some other cause, drew forth from Chatterton some severe reflections against the latter, who afterwards found it necessary to publish a vindication of himself.

The details of business were ill suited to Chatterton's pursuits and habits, and the disappointment of his sanguine expectations, or the natural melancholy of his temper, threw him into despair, and even produced threats of destroying himself with his own hand. He was dismissed by his master, and, encouraged by the hope of literary employment in London, he visited the metropolis when he was little more than 17 years of age. For some time after his arrival, which was in the month of April 1770, he exhibited no small degree of industry in furnishing communications to the ephemeral pages of the various publications of the day. But the emolument derived from these exertions of his genius was not equal to his expenditure; he was soon reduced to the extremest indigence, and, oppressed with poverty and disease, in a fit of despair he put an end to his existence by swallowing poison. He died in August 1770, before he had reached the 18th year of his age.

Chaucer. With great powers of genius, Chatterton was remarkable for a violent and impetuous temper. His biographer says, that "he possessed all the vices and irregularities of youth, and that his profligacy was at least as conspicuous as his abilities." In the year 1777, were published in one volume, octavo, *Poems, supposed to have been written at Bristol, by Thomas Rowley and others, in the 15th century*, with an engraved specimen of one of the manuscripts; and in the succeeding year, appeared a similar volume, which was entitled, *Miscellanies in Prose and Verse*, by Thomas Chatterton, the supposed author of the poems published under the names of Rowley, &c. No subject ever excited a keener controversy than the authenticity of these poems, which was defended by the learned Jacob Bryant and by Dr Milles, dean of Exeter, while it is strenuously disproved by Mr Walpole, Mr Warton, Mr Tyrwhitt, and some anonymous writers. The more general belief now is, that they are the production of Chatterton himself, however extraordinary it may appear that they must have been composed before he was 16 years of age.

CHAUCER, Sir Geoffrey, the father of English poetry, was born in London in the year 1328, but of the course and place of his education no authentic record remains. Some have supposed that he prosecuted his early studies at Cambridge or Oxford, while others assert that he was educated in France, and after his return that he resided some time in the Temple to acquire a knowledge of the municipal laws of England. But it appears from the contradictory statements of his biographers, that the events of his early life are veiled in obscurity. It is supposed that Chaucer had nearly reached the 31st year of his age, before he was fortunate in attracting the notice of Edward III. and of securing the patronage of John of Gaunt, who continued afterwards to be his steady friend; and, about the same time or soon after, he had a residence near the palace of Woodstock. When Chaucer was in his 39th year, he received from Edward III. a pension of 20 merks per annum, a sum equal to L.200 of the present day; and five years afterwards he seems to have acquired a character of some political importance, when he was appointed king's envoy to Genoa. This appointment, and his interview with the poet Petrarch, while he was in Italy, have been also the subjects of controversy. Besides some other favours, he was promoted to the comptrollership of the customs of wool and skins in the port of London, was presented by the crown with a daily allowance of a pitcher of wine, which was commuted in the succeeding reign for an annuity of 20 merks, and enjoyed during the whole period of Edward the III.'s reign and John of Gaunt's influence an uninterrupted course of prosperity. But in the time of Richard II. the successor of Edward, the poet seems to have been involved in a dispute between the court and the city of London, and Chaucer seems to have taken part with the latter, the consequence of which was, a temporary exile to the continent, and imprisonment in the tower when he returned to England, and it is said that he obtained his liberation by a confession not very honourable to his memory. The return from Spain into England in 1388, of John of Gaunt, who was now duke of Lancaster, and afterwards married the sister-in-law of the poet, was an era peculiarly favourable to the fortune of Chaucer. In the next year he was promoted to lucrative official situations; and when he had reached the 63d year of his age, he retired in some degree from public life, and it is supposed resumed his residence at Woodstock, where he was chiefly engaged in the composition of his *Canterbury Tales*.

When Henry IV. the son of his patron, John of Gaunt, ascended the throne of England, some of the grants and pensions of which he had been deprived, or which he had voluntarily relinquished in the preceding reign, were restored to Chaucer, but he lived only a short time to enjoy the munificence of his royal relative. He died in October, in the year 1400, which was the commencement of the second year of the reign of that monarch, and was interred in Westminster abbey, where, 150 years afterwards, a monument was erected to his memory by Nicholas Brigham, a gentleman of Oxford, and a warm admirer of his poetry.

Chaucer was not only the first, but also one of the best English poets. He was great in every kind of poetry, and displays every kind of excellence, excepting melody and accuracy of measure, defects which are to be ascribed to the imperfect state of the language and the infancy of the art, rather than to deficiency of talent or want of genius. "As he is the father of English poetry," says Dryden, "so I hold him in the same degree of veneration as the Grecians did Homer, or the Romans Virgil. He is a perpetual fountain of good sense, learned in all sciences, and therefore speaks properly on all subjects. As he knew what to say, so he knew also when to leave off, a continence which is practised by few writers, and scarcely by any of the ancients, except Virgil and Horace." *The Court of Love*, which was the earliest production of the poet, was composed when he was only in his 18th year. The story of *Troilus and Cresseide* was the next offspring of his genius, but although the names and scenery refer to classical antiquity, the sentiments and manners are connected with modern and chivalrous times. Many of Chaucer's poems, as the *Dream*, the *Boke of the Duches*, the *Romaunt of the Rose*, the *Flower and the Leaf*, and *the House of Fame*, are drawn up in the form of allegory. But the *Canterbury Tales*, the finest production of his muse, are alone sufficient to transmit his name to posterity. The plan of that work is borrowed from the *Decameron* of Bocaccio, and the subject is the journey of some travellers on a pilgrimage to Canterbury, who engage to entertain each other with stories by the way, and he who tells the best story is to be treated with a supper at the joint expence; and in his delineation of character he is not considered inferior to Shakespeare himself. The Canterbury Tales of Chaucer were first printed by Caxton, and the first collection of his works was published in one folio volume, by William Thynne, London, 1542. They have been several times reprinted, and an elaborate life of the poet has been drawn up by Mr Godwin.

CHEIRANTHUS, Stock Gilly-Flower, or Wall-flower, a genus of plants belonging to the Tetradynamia class.

CHELIDONIUM, Horned or Prickly Poppy, a genus of plants belonging to the Polyandria class.

CHELMSFORD, the capital of Essex in England, contains more than 4000 inhabitants, and has in its vicinity two extensive barracks, which are capable of accommodating 4000 troops.

CHELONE, a genus of plants belonging to the Didynamia class.

CHELTENHAM, a town of Gloucestershire in England, which includes, with the parish, more than 8000 inhabitants, and is chiefly celebrated on account of its mineral waters, which attract numerous visitors during the summer season.

CHEMISTRY.

Introduction.

When certain bodies are brought into contact, so that they shall act on each other, certain changes, some of which are very remarkable, invariably follow. These changes will be best illustrated by a few simple experiments.

Exper. 1.—An infusion of violets or red cabbage, which affords a blue colour, is prepared by the addition of boiling water to the vegetable substance, and allowing it to remain for some time to extract the colouring matter. If to a portion of this blue infusion, a few drops of spirit of hartshorn of the shops be added, a beautiful green colour is produced; but if a little vinegar be added to another portion of the same blue infusion, it is converted into a fine red colour; and hence blue vegetable infusions are employed as convenient tests of acid and alkaline substances.

Exper. 2.—If to a solution of green vitriol, sulphate of iron of modern chemistry, an infusion of nut galls, which are both nearly colourless and transparent, be added, the mixed liquids become of a deep black colour. Common writing ink is the product of this mixture.

Exper. 3.—If to the same solution of green vitriol, a solution of prussiate of potash be added, the liquid becomes cloudy, and a matter of a rich blue colour falls to the bottom. The substance thus produced is Prussian blue.

Exper. 4.—If to a solution in water of the well known substance sugar-of-lead, a small quantity of oil of vitriol or sulphuric acid be added, a white

Introduction.

cloud is formed in the mixture, and a copious precipitate is produced.

Exper. 5.—Reduce a small quantity of common pit coal to a coarse powder, and introduce it into the bowl of a tobacco pipe, cover it up with a little moist clay, when it is dry expose it to heat in the open fire, and when it has become red hot apply a light to the end of the tube, a particular kind of air, or gas in the language of chemistry, will continue to burn for some time. The air thus produced is familiar to every one in the gas lights.

These experiments will enable the student to form a more distinct notion of the nature of chemistry than any definition which has been yet proposed. It is the object of chemistry to investigate the changes which are produced by the action of certain bodies on each other, to discover in what circumstances those changes take place, or the laws which are observed during the process, and to examine the result which is obtained. This science, therefore, is occupied in tracing the nature, laws, and result of the changes now alluded to.

In all the changes which are produced by the accession or abstraction of heat or light; in all the changes which are produced by the combination of two bodies, and the formation of a new compound, chemical action appears. Considering then the multifarious changes to which the bodies in the material world are constantly subject; considering the diversified nature and endless variety of forms which those bodies by every new change exhibit, and considering the astonishing results obtained by the most simple means, which appear in the compounds produced, it is obvious that the sphere of chemical action is wide and extensive, and indeed is only limited by the bounds of the material world itself. For wherever the effects of light and heat are felt, few, or perhaps no kinds of matter, even those which seem the least susceptible of change, are exempted from their influence.

By what means are the wonderful changes which appear on the return of spring, accomplished,—when nature emerges from the gloom and rigour of winter,—when the vegetable tribes resume their verdure, when the buds unfold their leaves,—when the flowers display in gay profusion a thousand various hues, delight the eye with endless beauty, and fill the air with fragrant perfume? Or to what is to be ascribed the maturing influence of summer, diffusing joy and plenty around? These astonishing effects, for so we should consider them if they were less familiar, are owing to the operation of heat, one of the most powerful agents, or rather to the united operation of light and heat. But their effects not confined to the vegetable creation. Myriads of animals, whose vital functions had been suspended, are invigorated by the same powers, and restored to a new existence; the air, the earth, the waters, swarm with life; every leaf has its inhabitants; every tree is peopled with innumerable living tribes.

In examining the nature, properties, and constitution of the atmosphere, the aid of chemistry is essentially requisite; in the extraction of metals from their ores, and in converting them to the numerous purposes to which they are applied in civilized society, almost all the processes are chemical;—in investigating the nature, functions, and uses of vegetables, whether in the living or dead state;—in acquiring a knowledge of the functions and properties of animals;—and in the application of many parts both of vegetable and animal matter to a thousand valuable purposes, chemistry furnishes the principal means; and hence it must be an important guide in agriculture, as it has been long regarded as a material branch of medical education.

The application of chemistry to the improvement of the arts of civilized life, opens a wide field of contemplation. In many of these arts, as in the manufacture of glass and porcelain, in tanning, soapmaking, dyeing, bleaching, baking, brewing, distilling, and in most of the culinary arts, almost all the processes depend on chemical principles; and it may be added, that there are numerous little processes in various branches of domestic economy, where even a slight knowledge of chemistry may often prove highly useful. But without extending farther these preliminary remarks on the utility and advantages of chemistry, the following exposition of its principles and practice, will afford abundant proof of the importance and universal application of the science.

This treatise is divided into three parts. Part I. is devoted to an explanation of the principles of chemistry; in Part II. the phenomena of nature will be illustrated according to these principles; and Part III. comprehends a rapid sketch of the processes of art, or of some of the principal arts and manufactures which depend on chemistry.

PART I. PRINCIPLES OF CHEMISTRY.

Exclusive of light and heat, the bodies which constitute the elements of chemical investigation, are oxygen gas, azotic gas, hydrogen gas, carbone, phosphorus, and sulphur; three alkalies, nine earths, and twenty-seven metals; and if to this number be added chlorine, with the bases of fluoric and boracic acids, the subjects of later discoveries, the whole will amount to forty-eight. In treating of these bodies, the simple and most natural arrangement is to examine them according to the simplicity of their constitution, and their importance as chemical agents; and in investigating the properties of any body, its habitudes and combinations with those which have preceded, will be particularly detailed. In this way much anticipation is avoided; and while the science is fully illustrated, all theoretical views, on which peculiar methods of arrangement are constructed, are excluded. But before proceeding to the examination of individual substances, it is necessary to be acquainted with the properties and effects of light and heat, which have so large a share in all combinations and decompositions; and it is even requisite that this knowledge be preceded by a brief enquiry into the nature of those circumstances in which these decompositions and combinations are effected, or of the laws of affinity. These topics will form the subjects

Affinity.

of the first two chapters, and the others will follow in the order in which they have been enumerated.

Chapter I. Of Affinity.

All bodies in nature are attracted or drawn towards each other by a certain force. It is a familiar fact, that a stone when it is unsupported falls to the ground; the planets which revolve round the sun are attracted by that luminary as their centre of motion; polished surfaces of marble, glass, or metal, adhere together, and require for their separation a considerable force; a piece of wood or stone cannot be broken or drawn asunder without powerful exertion; and lime and sulphuric acid enter into such close combination, as not to be separated without a great degree of force. Whatever be the nature of these attractions, whether they are to be ascribed to the same universal power or property pervading all matter, they have been distinguished by different names. The attraction existing among the heavenly bodies was denominated by Sir Isaac Newton by the general term *attraction;* and he proved it to be the same as gravitation, or the descent of heavy bodies towards the earth;—that it is an essential property of all matter;—that the minutest particles, in proportion to their bulk, as well as the largest masses, are equally under its influence;—and that the same power which retains the planets in their orbits, gives a globular form to the drops of rain. That attraction which keeps polished surfaces in close contact is called *adhesion;* when particles of matter of the same nature are held together or attracted, the expression of the force by which this is effected is denoted *cohesion, homogeneous affinity,* or the *attraction of aggregation*; but when particles of a different nature enter into combination, the force or attraction is denominated *heterogeneous affinity,* the *attraction of composition,* or more properly *chemical affinity.*

Sect. I. *Of Adhesion.*

That force which retains different substances in contact with each other, is called *adhesion.* It takes place either between two solids, as marble or glass, or between solids and fluids, as glass and water. When the finger is brought into contact with water, the latter adheres to it, or the finger is said to be wet; and a strong attraction exists between gold and mercury.

Two plates of glass of one-tenth of an inch in diameter, required a force equal to 19 oz. to separate them; and a polished plate of glass being suspended from the arm of a balance, and placed in contact with a surface of mercury, nine grains were necessary to separate the two surfaces; and the whole apparatus being placed under the receiver of an air pump which was exhausted of the air, exactly the same force was found requisite to produce the separation of the surfaces. The last experiment shews clearly that the adhesion of the two substances was not owing to the pressure of the air, but to the attraction between themselves. When the same disk of glass was brought into contact with pure water, it adhered with a force equal to 258 grains, and to the surface of a solution of potash with a force equal to 210 grains.

In some curious experiments on this subject by Morveau, plates of different metals, an inch in diameter, and of equal thickness, quite round and well polished, were prepared. To keep them suspended parallel to the horizon, each plate was furnished with a small ring in the centre, and this being connected with the arm of a delicate balance, it was exactly counterpoised by weights in the opposite scale. The plate was then applied to the mercury by sliding it over its surface to exclude the air, and weights were added in the opposite scale, till the adhesion between the plate and the mercury was broken. From the result of these experiments it appeared that gold adheres with a force equal to 446 grains, silver equal to 429 grains, tin equal to 418 grains, lead equal to 397 grains, copper equal to 142 grains, iron equal to 115 grains, and cobalt equal to 8 grains only.

This investigation was farther prosecuted by Achard of Berlin, who made a great number of experiments on the force of adhesion between disks of different solids, as glass, rock-crystal, sulphur, wax, horn, and metals, with water and other fluids, at different temperatures. A glass disk of one inch and a half in diameter, was found to adhere to the surface of water at the temperature of 141°, with a force equal to 81 grains; at the temperature of 95°, with a force equal to 89 grains; and at the temperature of 43°, with a force equal to 97 grains. From these results it appears that the force of adhesion is diminished by the diminution of the temperature.

Sect. II. *Of Cohesion.*

When particles of the same kind of matter are united, the force with which they are held together is called cohesion, or the attraction of aggregation, or homogeneous affinity. This force is probably of the same nature with that of adhesion, but different in degree. A greater force is necessary to separate the particles of a mass of marble than two polished surfaces of the same matter when they are brought into contact.

The force of cohesion is very different in different bodies. A great force is requisite to overcome the power of cohesion among the particles of a wire of gold, or of iron, but a small degree can separate the particles of a piece of wood or stone. A series of experiments was instituted by Muschenbroeck to ascertain this force. Rods of an inch square, of the different substances examined, were suspended perpendicularly, and the amount of the weight necessary to destroy the cohesive force of the particles being attached to the lower extremity of the rods, was considered as the measure of that force. Among the metals, a bar of steel required 135,000 pounds to break it; a bar of iron 74,500 pounds; a bar of cast gold 22,000 pounds. Among the alloys of the metals, gold two parts silver one part, 28,000 pounds; copper six parts, tin one part, 55,000 pounds; brass 51,000 pounds. Among the woods, a rod of the locust tree, 20,100 pounds; beech and oak 17,300, pounds; pitch pine 7,656 pounds; among bones, ivory 16,270 pounds; horn 8,750 pounds; and whalebone 7,500 pounds.

All bodies in nature exist in three different states, which are quite distinct from each other; in the form of solid, liquid, and in that of elastic fluid. The diversity which exists among solid bodies, arises no doubt from the various degrees of cohesive force among the particles of which they are composed. It is the peculiar property of fluids to admit of free motion among their particles by the application of any force. In liquids, as water or mercury, an attractive power exists; but in elastic fluids, as air, a repulsive power, which is increased or diminished by changes of temperature, is a characteristic property; or perhaps it should rather be said that the force of affinity between the particles of elastic fluids is extremely weak, and is therefore more sensibly influenced by the slightest changes of temperature.

Solution.—The force of cohesion between the particles of many solid bodies, is less strong than the affinity which exists between the same particles and certain liquids; thus, if a portion of common salt be introduced into water, the affinity between the particles of the salt, which were collected together in masses in the form of cubes, is overcome by the stronger affinity of the same particles for the water. This process is well known in familiar, as well as chemical language, by the name of *solution.* But this affinity between the water and the salt has also its proper limits, a certain proportion can only be dissolved, and if more be added it falls to the bottom unchanged. In many cases, a larger portion of saline matters, even to double the quantity, is dissolved in boiling water, than in the same liquid at the ordinary temperature of the atmosphere. Whatever be the proportion of the solid body dissolved, it is equally diffused throughout the whole mass of liquid, which remains as transparent as before the addition of the saline matter; and when the quantity of liquid is diminished, the particles of the dissolved body are brought nearer together, so that the power of affinity resumes its action, and they are restored to the solid form. In those cases in which the increased temperature of a liquid enables it to dissolve a larger proportion of salt, when that temperature is diminished the cohesive force between the particles of the salt and the liquid is weakened, while the affinity between the particles and the salt begins to act, and it becomes solid.

Crystallization.—The diminution of the mass of liquid in which any saline body is dissolved, whether it be effected at the ordinary temperature of the atmosphere, or by the application of artificial heat, is called *evaporation*; the process by which the saline substances return to the solid form is called *crystallization*; and the same bodies when dissolved in the same liquid, and treated in the same way, invariably assume the same form.

No bodies can assume the form of crystals, excepting those which can be reduced to the state of fluid. But many substances which are not soluble in any liquid, assume regular forms, as is the case with glass, sulphur, and metallic substances, which are brought to the state of fusion by combining with heat, and the particles being separated from each other, or the affinity of aggregation being destroyed, they are left at liberty to arrange themselves into determinate forms, or to crystallize.

Many of those saline substances which arrange themselves in certain determinate forms, combine with a considerable portion of water, which, in such cases, constitutes part of the solid; and to this water, which is called the water of crystallization, as well as to the uniform distribution of the particles of the salt themselves, is no doubt owing the transparency of many crystalline bodies.

Efflorescence and Deliquescence.—Some salts which form crystals from solution in water, when they are exposed to the air readily part with their water of crystallization; this process is called *efflorescence*; and it is owing to the weak affinity between the particles of the salt and the water which had combined with it during its crystallization. As this process proceeds, the surface of the crystallization loses its polished appearance; it becomes dull and opaque, and at last the whole falls down into powder. Very opposite effects take place on other salts when placed in the same circumstances; instead of giving out moisture, they attract it from the atmosphere, and some of them in such quantity as in a very short time to be reduced to the state of liquid. Of the first kind, or efflorescent salts, soda, and its combination with sulphuric acid, forming common Glauber salt furnish good examples; and of the second kind, or the deliquescent salts, potash, or muriate of lime, is an equally appropriate instance.

In conducting the crystallization of salts, it is an object to have them in the most perfect form, and of a large size, that the form may be distinctly seen. This branch of practical chemistry has been successfully cultivated by M. Leblanc, and the results of his experiments and observations have been published in a memoir *Jour. de Physique*, 55.300. The process must be conducted in flat-bottomed vessels of glass or porcelain, and they should be kept at perfect rest; the salt must be in a state of purity, and it is necessary to attend to the degree of specific gravity at which the solution begins to form crystals. If the specific gravity, or the quantity of salt, be too great, the crystals which are formed are heaped together in confused masses; and no crystals are obtained when the specific gravity is too small, or the solution too weak. When the solution which is of sufficient strength has been allowed to cool slowly, a small number of crystals is obtained. These crystals have no other defects than what arise from their contact with the vessel, and sometimes perfect crystals are found among them. These more perfect crystals are to be separated from the rest, and by changing their position in the solution daily, they may be obtained in the completest form, and of the largest size. For this purpose, new solutions of the same salt are prepared, and being brought to that degree of concentration which affords crystals in a mass, this mass being removed, the single crystals are introduced, either by disposing them in the vessel, and pouring on the solution, or after the latter is put into the vessel, and distributing the crystals on the bottom. All that is necessary for promoting the increase and perfection of the crystal is the frequent change of its position, keeping up the solution to a proper degree of strength, and allowing it to remain at perfect rest during the process. When the crystals are left too long in the solution, or when the solution is too weak when they are introduced, instead of increasing in bulk they begin to diminish, and are partially dissolved. This may be known by the edges, or angles, becoming less sharp.

Forms of crystals.—The regular forms which many bodies assume, either in the process of nature or in artificial solutions, could not fail to attract the attention of naturalists and chemical philosophers. The investigations of Bergman and Romé de L'Isle, and more lately the researches and speculations of the Abbé Hauy, have been particularly directed to this curious subject.

According to the ingenious theory proposed by the Abbé Hauy, the integrant particles always combine in the same way; they unite by the same faces, or the same edges, but these faces and edges are different in different crystals. Whatever variety of forms the same substances assume during crystallization, they all contain a nucleus, or primitive form, which may be extracted by careful mechanical division. In the examination of crystals, Hauy found that all the primitive forms might be reduced to six, namely, 1. the *parallelopiped*; 2. *tetrahedron*; 3. *octohedron*; 4. the *regular six-sided prism*; 5. the *dodecahedron*, with equal rhombs; 6. the *dodecahedron*, with triangular faces, composed of two six-sided pyramids, united base to base.

But it was found by the same philosopher, that the nucleus, or primitive form of a crystal, is not the last term of its mechanical division, for it may be subdivided not only parallel to its different faces, but sometimes also in different directions. In those cases where the primitive form is a parallelopiped, which is unsusceptible of subdivision, excepting in a direction parallel to its faces, it is obvious that the *integrant particle*, or *molecule*, the denomination given by Hauy to the last term of the mechanical division of a crystal, must be similar to the nucleus itself. Guided by experiment, he has reduced the integrant particles of all crystals to the three following figures: 1. the tetrahedron, or the simplest of all pyramids; 2. the triangular prism, or the simplest of all the prisms; 3. the parallelopiped, or the simplest of the solids having their faces parallel.

From these primitive forms the author supposes that the difference of size, proportion, and density of the different particles of bodies may account for all the differences of affinity which take place in simple aggregation and composition. In the formation of primitive crystals the integrant particles unite, sometimes by their faces and sometimes by their edges, thus giving rise to the different figures of the primitive crystals which are composed of integrant particles of the same form. But in the crystallization of bodies the same primitive form is not always exhibited; the deviations from this form, and the variety of crystals thus produced, are called by Hauy secondary forms, in some cases; for example, the primitive form is the octohedron, but in deviating from this form certain salts during crystallization assume that of the cube or dodecahedron.

Pursuing this theory, the primitive form and that of the integrant molecule being determined, the laws according to which the molecules are combined to produce around the primitive form those kinds of coverings which terminate so regularly, and from which figures so different from each other, although originally of the same substance, are produced, are next to be investigated. From examining the mechanism of the structure of crystals subject to these laws, that all the parts of the secondary crystal superadded to the nucleus are formed of *laminæ* or plates which decrease regularly by subtractions of one or more ranges of integrant molecules, so that theory determines the number of these rows, and consequently the form of the crystal. The various secondary forms depend on decrements at the edges or the angles, intermediate decrements, and mixed decrements. But for a full view of the theory, and its curious details, the reader is referred to the author's *Traite de Mineralogie*, vol. i.; or to *Annales de Chimie*, vol. xvii.

Sect. III. *Of Chemical Affinity.*

Chemical affinity, or what is otherwise called the attraction of composition, takes place between the particles of different kinds of matter; and the result of this combination is a new compound, different in its properties from the ingredients of which it is composed. This difference in the properties of the compound obtained from the combination of two substances, may be considered as the character of chemical affinity.

This affinity does not exist between the particles of all kinds of matter. No action takes place between the particles of a piece of marble and water; but if a portion of muriatic acid be added, the marble is dissolved, and a uniform transparent liquid is obtained.

It is the peculiar characteristic of chemical affinity that the compounds formed by the combination of two substances have new properties different from those of their constituent parts. In some cases two mild and insipid substances afford a compound which is highly acrid and corrosive, and the combination of two very corrosive substances presents a mild and insipid compound.

Changes of colour.—Lead which is of a bluish white colour, when it combines with oxygen becomes of a bright yellow or red; the metal called cobalt is of a grey colour, but assumes a fine blue when combined with oxygen; and copper, which is red, when combined in the same way presents a green colour.

Changes in smell.—The smell of ammonia or volatile alkali is extremely pungent; the smell of muriatic acid is still more pungent; but when the two are united, the compound formed, which is sal-ammoniac, is perfectly inodorous. No example, indeed, can be given, which affords a better illustration of the effects of chemical combination, in which two highly volatile substances become fixed in the compound, and exhibit an entire change of their most obvious properties. In the uncombined state the smell of sulphur or of potash is scarcely perceptible; but if they are fused together into a mass and moistened with water, a very offensive odour is exhaled.

Changes in taste.—Sulphur is nearly insipid, and oxygen, which is one of the constituent parts of the atmosphere, is not only innocent, but essentially necessary for the support of animal life; but when the two bodies enter into combination, the compound thus formed, which is oil of vitriol or sulphuric acid, is well known as one of the most corrosive substances. Sulphuric acid, which is sour and corrosive, when combined with soda, which in its pure state is also of a corrosive quality, forms a compound of a bitter nauseous taste, having none of the properties of its component parts. The new compound is Glauber salt, or sulphate of soda.

Changes in constitution.—The effects of chemical action in changing the constitution of bodies, are not less remarkable. Water in the solid state, or ice, when combined with heat becomes a transparent liquid; and this liquid having entered into combination with a larger portion of heat, assumes the form of vapour, which is an invisible elastic fluid. A large portion of water disappears when it is thrown on newly burned lime; part flies off in the state of vapour, but part enters into combination with the lime and becomes solid. Ammonia, or volatile alkali, in the state of elastic fluid or gas, is equally invisible with common air; muriatic acid gas is also transparent and invisible; but when they are united, a white solid substance, or sal-ammoniac, is the result.

Many of the most important operations in chemistry depend on the different force of affinity which exists between different bodies. Two kinds of affinities have been described and distinguished by the names of *simple* and *compound*, or, as it is sometimes expressed, simple elective attraction, and double elective attraction. The word elective was used to signify a choice or preference which one body had for another.

Simple affinity.—This kind of affinity includes all those combinations which take place between two bodies without the intervention of others, as when an acid and an alkali combine together when they are brought into contact.

Experiment 1.—To a quantity of muriatic acid add small bits of marble, till the effervescence ceases. This is an example of simple affinity. The marble consists of lime and carbonic acid; but the muriatic acid, having a stronger affinity for the lime than the carbonic acid, combines with it, and the carbonic acid being set free, passes off in the state of gas, which is the cause of the effervescence.

Exper. 2.—Introduce into a retort a portion of the salt called acetate of soda, which is a compound of acetic acid and soda, add some muriatic acid, and apply heat till the whole is reduced to a dry mass. The muriatic acid having a stronger affinity for the soda, combines with it, and the acetic acid is driven off.

Exper. 3.—Add a quantity of nitric acid to the dry mass in the retort, which is muriate of soda, and apply heat, the muriatic acid will be separated and pass off in the state of gas, and the nitric acid unites with the soda.

Exper. 4.—The dry mass remaining in the retort is a compound of nitric acid and soda or nitrate of soda. Let a portion of sulphuric acid be added and heat applied, the nitric acid will be driven off, and the sulphuric acid will combine with the soda.

These experiments are all cases of simple affinity, and in the last three the muriatic, nitric, and sulphuric acids being successively brought into contact with the several compounds of the soda, unite with it in consequence of the superior force of affinity. These changes of affinity are sometimes represented by diagrams, as in the following example of simple affinity.

Muriate of soda. { Muriatic acid
20
Soda 25 sulphuric acid.

Sulphate of soda.

When it is an example of simple affinity, as in this case, a single bracket is employed. The substance to be decomposed is placed on the outside, and the name of the new compound, which is the sulphate of soda, is placed below the lower horizontal line; the constituents of which it is composed above the same line, and the name of the substance which is driven off is placed below the upper horizontal line. In this case the muriate of soda is decomposed by sulphuric acid, and a new compound, sulphate of soda, is obtained, while the muriatic acid is expelled. The terms *quiescent* and *divellent* are sometimes used in speaking of the force of affinity. In this case the quiescent affinity is that which operates between the muriatic acid and the soda; and the divellent affinity exists between the sulphuric acid and the soda: and here it is obvious that no decomposition or change can take place unless the latter be greater than the former. The former of these affinities is sometimes expressed by numbers, as, in the above case, the number 20 denotes the quiescent affinity, and 25 is expressive of the divellent affinity.

Compound or double affinity.—It sometimes happens that no decomposition takes place by the addition of a third substance, in consequence of the stronger affinity already existing between the two substances in combination. Thus, the decomposition of sulphuric acid and zinc, or sulphate of zinc, cannot be effected by means of acetic acid, because the affinity of the zinc for sulphuric acid is stronger than the affinity of the zinc for acetic acid; or the quiescent affinity is superior to the divellent affinity, and therefore no change can take place. But if a fourth substance be introduced which has an affinity for one of the constituents in the compound, the quiescent affinity may be overcome, and a decomposition may be effected. Lead has a strong affinity for sulphuric acid. If, then, a solution of the compound of acetic acid and lead, or sugar-of-lead, be added to a solution of sulphate of zinc, a change is immediately produced, because the combined or divellent affinities of the acetic acid and the lead are greater than the quiescent affinities of the sulphuric acid and the zinc, and as one of the new compounds, the sulphate of lead, is insoluble in water, it falls to the bottom, or, in the language of chemistry, is precipitated. Cases of compound affinity are also represented by diagrams, of which the following is an example.

Acetate of zinc.

Sulphate	Zinc 6 acetic acid	Acetate
of	9 4	of
zinc.	Sulphuric acid 12 lead.	lead.

Sulphate of lead.

In the above diagram the names of the substances to be decomposed are placed on the right and left sides of the upright brackets, and their quiescent affinities are expressed by the numbers 9 and 4, equal to 13. The affinity of the acetic acid for the zinc is denoted by 6; but the affinity of sulphuric acid for zinc is equal to 9, and hence no change can be effected by the addition of acetic acid. But the acetate of lead being introduced, a double decomposition follows; for then the strong affinity of the sulphuric acid for the lead counterbalances the quiescent affinities, and contributes to produce the change. The sum of the quiescent affinities is equal to 13, but the sum of the divellent affinities is equal to 18; and therefore a decomposition must take place. In speaking of metallic substances, it may be observed that the name of the metal is mentioned in combination with the acid to render the explanation less complicated, instead of the oxides, which alone unite with acids.

But it has been maintained by Berthollet, an ingenious French chemist, that a decomposition may be effected by increasing the quantity of the substance with which a new compound is desired. Thus, for example, the compound of sulphuric acid and barytes is insoluble, either in hot or cold water; and sulphuric acid has a very strong affinity for the earth. Sulphuric acid has also an affinity for potash, although it is much weaker than the affinity between the same acid and barytes; but equal quantities of pure potash and sulphate of barytes being boiled together, a partial decomposition was effected. In another experiment the oxalate of lime was partially decomposed by means of pure potash, although the affinity of the oxalic acid for lime is much greater than the affinity of that acid for potash. But those who have adopted the doctrine of definite proportions explain these experiments on the supposition that a double decomposition had actually taken place, and that carbonic acid, having combined with the potash during the process, had a considerable share in the decomposition.

Definite proportions.—When a compound body, of which the constituent parts are known, invariably exhibits the same characters and the same individual properties, it is natural to suppose that the substances which enter into its composition are always in the same proportion. When certain bodies are placed in the same circumstances they acquire, by their combination, precisely the same qualities, at least as far as these qualities fall under the cognisance of our senses. This view of the elements of different kinds of matter entering into combination in the same proportions, accords with the undeviating constancy and beautiful uniformity which, when the same causes operate, are observed in all the other processes of nature which the human mind is capable of appreciating.

The ancient Greek philosophers held the doctrine that matter is composed of indivisible atoms; the same doctrine is adopted by the moderns, and it now forms a prominent feature in the more refined speculations of chemical science.

This doctrine seems to have been first started by Mr Higgins of Dublin about the year 1789. Deriving his opinion from the corpuscular philosophy, that chemical compounds have definite proportions, as atom with atom, or one with two, or three, or a greater number, he applied it to those gases which combine in more than one proportion; and supposed that all the proportions of the same element are equal. In 1802 Mr Dalton adopted the same doctrine, and extended his views to chemical compounds in general; and his views are fully illustrated in his *Chemical Philosophy*. Richter of Germany began early to prosecute the same subject, which has been followed out by some of the first chemists of Britain and France, and still farther investigated by Berzelius of Sweden.

Exper. 1.—Take one part in bulk of oxygen gas, and two parts of hydrogen gas, and let them be mixed together in a glass tube in the mercurial trough, and the tube being furnished with apparatus for passing the electric spark through it, if the gases be inflamed they entirely disappear, and nothing remains but a small portion of water.

Exper. 2.—But if two parts of oxygen, and two of hydrogen, by bulk, be treated in the same way, one part of oxygen remains uncombined; and in whatever proportions the two gases are mixed together, one volume of oxygen is invariably found to unite with two of hydrogen; and hence it is naturally inferred that the elements which enter into the composition of water, always combine in the same proportions.

Exper. 3.—Fill a jar two-thirds with oxygen gas, and introduce a piece of charcoal into the jar, over mercury, which is to be brought to the same level, both on the inside and on the outside. The charcoal being set on fire by means of a burning glass, the gas is at first expanded, but when it recovers its former temperature its bulk is nearly the same; and the whole of the oxygen, provided the quantity of charcoal be sufficient, is converted into carbonic acid. But in whatever way they are formed, the densities of oxygen gas and carbonic acid gas are to each other as 34 to 47 nearly; and from this it follows that carbonic acid must always contain the same weight of the base carbone and oxygen. The proportions by weight are 5.7 of the charcoal, and 15 of oxygen.

Exper. 4.—If two parts in volume of the gas called carbonic oxide, with one part in bulk of oxygen, are inflamed over mercury by the electric spark, two volumes of carbonic acid gas are obtained; the weight of which corresponds precisely to the weight of the carbonic oxide and oxygen gas employed. From this experiment it is obvious that the carbonic oxide contains only half as much oxygen as carbonic acid; so that the proportions of carbone and oxygen in carbonic oxide, are 5.7 of the former, and 7.5 of the latter. The decomposition of carbonic acid by electricity leads to the same result; for if two volumes of carbonic acid be treated in this way over mercury, two volumes of carbonic oxide and one volume of oxygen remain; and thus the composition of this gas is established, both synthetically and analytically.

In cases where a liquid and a solid enter into combination, the same determinate proportions are observed to take place. In the compound which is obtained by combining sulphuric acid with the earth of barytes, the solid precipitate of sulphate of barytes is uniformly found to consist of about 34 parts of acid and 66 parts of barytes, in the 100 parts of the compound.

When a mutual decomposition between two neutral salts is effected by an interchange of their elements, no excess of acid or of base appears. The new compounds are always perfectly neutral. Nitrate of barytes consists of 41 parts of acid, and 59 parts of the earth in 100 parts of the compound, and 67 parts of sulphate of potash, are composed of 30 of acid, and 37 of alkali. If a solution of the neutral salts in the proportions now mentioned, that is, 100 parts of nitrate of barytes and 67 parts of sulphate of potash, be mixed together, 89 parts of sulphate of barytes and 78 parts of nitrate of potash are obtained by the decomposition; and hence it appears that 30 parts of sulphuric acid combine with 59 of barytes and 41 parts of nitric acid, unite with 37 parts of potash.

The compounds of elastic fluids with solid substances, exhibit the same determinate proportions. The proportion of carbonic acid obtained from the sub-carbonate of potash, is exactly half the quantity obtained from the carbonate of the same alkali. In the black and the red oxides of iron, two proportions of oxygen combine with the former, and three proportions with the latter; that is, 100 parts of iron require 29 parts oxygen to be converted into the black oxide, and about 43.5 to become the red oxide.

But the reader who wishes to pursue this curious investigation may consult Dalton's *New System of Chemical Philosophy*, or Davy's *Elements*.

Chap. II. Of Light and Heat.

Light and heat act a very important part in the changes which are constantly going on among natural bodies. No change indeed takes place in which the one or the other is not either absorbed or evolved. In many of their properties, light and heat are analogous, but in some they are different. Both enter into combination with bodies; but light penetrates certain kinds of matter where the heat is in some degree interrupted; and heat is equally diffused through other bodies in which the progress of light is completely obstructed.

Sect. I. *Of Light.*

The sensation of vision is produced by the rays of light which proceed from the sun, or from burning bodies. Of the nature of light two opinions have been held. According to one of these opinions, all space is filled with a very subtile fluid; and this fluid being agitated or put in motion by the sun or burning bodies, is thrown into undulations or vibrations, which extend themselves to the eye, and render the bodies which have produced these motions visible. But according to the theory of Newton, light is supposed to be a subtile fluid, composed of peculiar particles of matter, which are constantly separating from luminous bodies, and entering the eye, excite the sensation of vision, or the perception of the objects from which it proceeds, or those from which it is reflected.

Physical properties.—The velocity of light is one of its most wonderful properties. It has been proved by astronomical observations, that it moves at the rate of 200,000 miles in a second; a velocity of which the human mind can form no distinct conception. Light passes from the sun to the earth in eight minutes, a space which a cannon ball, with its ordinary velocity, could not traverse in a shorter period than thirty-two years. The extreme minuteness of the particles of light may be inferred from its astonishing velocity; for as the impulse of moving bodies is in proportion to their quantity of matter multiplied by their velocities, if the one or the other or both be increased, the striking force is proportionably augmented; and hence if the particles of light were not exceedingly small, their excessive velocity would be highly destructive. Another proof of the great velocity of the particles of light is derived from the extreme facility with which they pass through transparent solid bodies, where they suffer no diminution of their velocity.

Reflection.—If a ray of light fall perpendicularly on a polished substance, it is thrown back in the same direction; but if the ray fall obliquely, it returns from the surface on the opposite side of a perpendicular line drawn from the point on which the ray falls, and at an equal distance from that perpendicular. The angle which the ray of light forms with the perpendicular as it falls is called the *angle of incidence*, and the angle which the ray of light forms with the same line when it is thrown back is called the *angle of reflection*. These two angles are exactly equal; and hence the optical law that the angle of incidence is equal to the angle of reflection.

Refraction.—If a ray of light pass in a direct line from one medium to another, as from air to water, or from water into air, it moves on in the same direction; but if it pass obliquely from one medium to another, it is bent from its former course, and then moves on in a new direction. This is called the *refraction of light*. A straight rod introduced obliquely into a vessel of water, appears bent at the place where it touches the surface, which is owing to the refraction of the rays of light passing from the rarer medium of the air to the denser medium of the water. When light passes from a rarer to a denser medium, as from air into water, it is refracted or bent towards the perpendicular; but when it passes from a denser into a rarer medium, it is refracted from the perpendicular. The quantity of this refraction is estimated by the density of the medium; but with this remarkable exception, that the refractive power of combustible bodies is in greater proportion than their density. Observing this fact in water and the diamond, Sir Isaac Newton threw out a conjecture that they are combustible bodies, a conjecture which has been fully verified by succeeding discoveries.

Prismatic spectrum.—When a ray of light is admitted through a small hole in the window shutter, and is received on a white surface, it forms a luminous spot; but if a triangular glass prism be interposed, the ray of light is not only refracted, but has assumed an oblong shape, and is divided into seven different colours. This image is called the *Prismatic Spectrum.* The colour and order of the seven rays are the following; and the spectrum being divided into 360 parts, the number of parts occupied by each of the colours are, red 45 parts, orange 27, yellow 48, green 60, blue 60, indigo 40, violet 80. As these different rays appear in different parts of the spectrum, their refractive power is different. Those rays which are nearest the middle are the least refracted, and those which are next the extremities suffer the greatest refraction. No farther change is produced on any of the rays by new refractions or reflections.

Transparency and opacity.—In its passage through some bodies, light seems to suffer no interruption. Such, for example, is glass or water; but it is interrupted in its passage through other bodies, as a piece of wood or stone. Bodies of the first description are said to be transparent, and those of the second kind are said to be opaque. This diversity of properties is not dependent on the density of the bodies, for water or glass is denser than wood. According to the explanation of Newton, the particles which compose transparent bodies are of equal density, and are uniformly arranged, and the light passing through them is equally attracted; but the particles of opaque bodies are of unequal density, and are unequally arranged, and the particles of light being unequally attracted, are constantly changing their course till they are finally interrupted.

The illuminating power of the different rays is very different; the brightest yellow, or the palest green, possesses the greatest power of illumination, which diminishes towards the extremities of the spectrum; and the violet ray is the most deficient.

Chemical properties.— Light, as well as other bodies, is subject to the universal law of attraction; it enters into chemical combination with many substances; and when such substances are placed in certain circumstances, the light which had combined with them is given out. This kind of light, which has been called *phosphorescent*, to distinguish it from that which is accompanied with perceptible heat, is given out by mineral substances, and during the decomposition of animal and vegetable matters.

Exper. 1.—Calcine in the open fire a few oyster shells, reduce them to powder, which is to be sifted through a fine sieve; mix three parts of this powder with one part of the flowers of sulphur; introduce the mixture into a crucible, and having pressed it firmly to the bottom, expose it to a red heat for an hour. When it is cool, scrape off the purest parts of the mass, and put it up in a well closed phial. The substance thus prepared, is *Canton's pyrophorus,* from the name of the discoverer. When it is exposed to the rays of the sun, or even to the light of day for a short time, the light which it gives out when carried into a dark place, renders objects distinctly visible. But being kept in the dark, it loses this property, which is only recovered by exposing it again to the light. When the light becomes feeble, or is nearly extinct, it may be revived or augmented by immersing the phial in hot water. This experiment shews that light is alternately absorbed and given out without inducing any perceptible change on the substance with which it combines.

Exper. 2.—Calcine a few clean oyster shells in the open fire or in a crucible, and preserving them entire, expose them to the sun's rays. When they are carried to a dark place, a beautiful light which is sometimes iridescent, is emitted. When the light is extinguished, it is again renewed by exposure to the sun's rays, and the iridescence is increased by calcining the shells in contact with iron or charcoal.

Exper. 3.—In a dark room, place a thin rhomboidal crystal of lime spar on a plate of iron which has just ceased to be red; in a short time a fine glow of white light appears, as if the whole mass were illuminated.

Exper. 4.—In the same circumstances put a quantity of blue Derbyshire spar on the plate of iron at nearly the same temperature, a great deal of a reddish purple light is extricated.

Exper. 5.—Divide a fresh herring longitudinally with a knife, and take about 4 drams weight, cut across, put it into a solution composed of two drams of Epsom salt dissolved in two ounces of cold water. On the second evening, a lucid ring is seen at the top of the liquid, and when the phial is shaken, it exhibits a fine luminous appearance, which continues for a day or two. Similar experiments may be made with common salt, sea-water, and Glauber salt, as well as with other fishes. *Phil. Trans.* 1800.

In the first and second experiments the light seems to have been absorbed and given out; in the experiments with the carbonate of lime and the Derbyshire spar, it seems to have entered as one of the constituents into the composition of these minerals, from which it is expelled by the application of heat, but is not recovered by a fresh exposure to the rays of the sun; and it appears to be one of the elements of organized matter which is separated at the commencement of decomposition.

The green colour of vegetables depends on the absorption of light; for when they are placed in other respects in the most favourable circumstances they become perfectly white; and on this principle the blanching of celery and other garden plants is practised, by which also their other qualities are greatly changed.

Sources of light.—The great source of light, as well as of heat, is the sun; and it appears from the experiments of modern philosophers, that the sun's rays are of three kinds: 1*st*, Rays which produce colour; 2*d*, Rays which produce heat; and, 3*d*, Rays which produce no perceptible light or heat, but some remarkable chemical effects. The rays which produce colour are within the limits of the visible spectrum; the rays which have the most powerful effect on the thermometer are beyond the limits of the red ray; and the rays which produce the greatest chemical effects are beyond the limit of the violet ray in the opposite extremity of the spectrum. These latter rays have the greatest power in reducing metallic salts or oxides.

Combustion is another copious source of light. Burning bodies in all cases give out light, so that it must have been one of the constituent parts of the substances which are employed in the process. Some bodies emit light when they are raised to a certain temperature without undergoing the process of combustion. Iron heated to 635° becomes visible in the dark; shines brightly at 752°, is luminous in the twilight at 884°, and shines in broad day only when the temperature exceeds 1000°.

Light is also given out by attrition or percussion, as when rock-crystal or quartz, or flint and steel, are struck against each other; and by rubbing two pieces of loaf-sugar smartly against each other a train of white light is thrown off.

Sect. II. *Of Caloric.*

In common language two different meanings are assigned to the word heat; to *feel* heat is meant the sensation excited in the body; but when the fire or a piece of metal is said to be hot, it denotes the power of exciting the sensation of heat existing in the piece of metal or the fire,—the one is the cause and the other is the effect. But to prevent ambiguity, the term *caloric* has been introduced into modern chemistry to signify the cause of the sensation.

Two opinions are held concerning the nature of caloric; according to one opinion it depends on a peculiar tremor or vibration, which is induced among the particles of heated bodies; but, according to another opinion, it is supposed to be a peculiar subtile fluid of a very elastic and penetrating nature, and universally diffused. The opinion of caloric being a distinct material substance, is most generally adopted, and seems to be most suitable for explaining the phenomena which accompany all the changes and effects which it produces.

The particles of caloric are attracted by other kinds of matter, and enter into combination with it; their velocity is the same as that of light, and their minuteness is not less. Like the rays of light, caloric is reflected from polished surfaces, and refracted when it is transmitted through transparent bodies.

Exper. 1.—Place two concave mirrors of tinned iron, of nine inches focus, at about twelve feet distance from each other; let a ball of iron of two inches diameter, heated to that degree so as not to be visible in the dark be fixed in the focus of the one, and the ball of a thermometer in the focus of the other. In a few minutes the thermometer will indicate a rise of temperature corresponding to the heat of the iron ball, and in consequence of the rays being reflected from the polished surface.

Exper. 2.—Substitute a lighted candle for the ball of iron, and a similar effect, though not in the same degree, will be produced.

Exper. 3.—Interpose a plate of glass between the two mirrors, while the heated iron ball is in the focus of one, and has previously raised the temperature of the thermometer, the interposition of the glass will immediately occasion a fall in the thermometer; thus proving that the rays of caloric are interrupted, while the rays of light are not perceptibly diminished. When the plate of glass is removed, the thermometer again indicates an increase of temperature.

Exper. 4.—Place the mirrors at the distance of ninety inches from each other, and let a glass vessel with boiling water be substituted for the iron ball in one focus, and a delicate thermometer in the other; suspend in the middle space between the mirrors, a common glass mirror, so that either side may be turned towards the glass vessel with the boiling water. When the polished side of the glass mirror is turned towards the glass vessel, the rise of the thermometer is very small; but when the other side, which should be darkened, is turned towards the glass vessel, the thermometer will rise three or four degrees. In one experiment conducted in this way, the thermometer rose three degrees, when the polished side of the mirror was presented to the boiling water, and nine degrees when the other side was turned to it.

These experiments prove clearly the reflection of the rays of caloric; they prove also that the rays of light and heat may be separated, and are not transmitted through all bodies with the same facility; and the intervention of the mirror in the last experiment shews a remarkable diversity of effect in the transmission of the rays of caloric by different surfaces of the same body.

1. *Equal distribution of Caloric.*

If a number of bodies of unequal temperatures be brought into contact with each other, or placed in the same medium, in a certain time they are all reduced to the same temperature, and indicate the same degree of heat. Thus, if one body be at the temperature of 50°, if another be raised to that of 100°, and a third to that of 200°; and if the three bodies be placed in the temperature of 80°, they will all in a short time acquire the same temperature. The body at the temperature of 50° will be raised to 80°, and the two bodies at the higher temperature will be reduced to the same degree. This is called the *equilibrium*, or equal distribution of caloric; and to whatever degree bodies are heated or cooled, they all acquire in time the temperature of the surrounding medium, when they are permitted to communicate freely with each other.

As bodies are deprived of caloric by radiation from their surfaces, as well as by direct communication with these bodies with which they are in contact, the difference of time in which bodies of a different nature acquire the same temperature is very considerable,—since it must depend on the nature of the surface which gives out or receives caloric, and on the conducting power which is also very different in different kinds of matter. Bodies which are good conductors of caloric, cool most rapidly.

Exper. 1.—Take a pound of mercury and a pound of water in different vessels, and having raised them to the temperature of 100°, let them be placed in a medium, the temperature of which is 50°, the mercury will be found to have acquired the temperature of the surrounding medium in a much shorter time than the water, because it is a much better conductor of heat.

2. *Motion of Caloric.*

When caloric passes from one body to another, it is either transmitted from the heating body through the intervention of another in contact with the body which receives the caloric, and in this case it is said to be *conducted*, and then it passes slowly; or it is directly transmitted without the intervention of other bodies, as when the heat proceeds from the sun or from the fire, and then it is said to be *radiated*, in which case the passage of the rays of caloric is comparatively instantaneous.

Conducting power of bodies.—The conducting power of different bodies is very different; metallic substances are the best conductors; porous substances, as cork, wool, feathers, or furs, allow caloric to pass through them very slowly, and are therefore bad conductors; and hence woollen stuffs and furs answer best for clothing in cold countries, because the heat of the body is very slowly dissipated by their inferior conducting power. The remarkable diversity in the conducting power of bodies may be shewn by a simple experiment.

Exper. 1.—Take a rod of iron and a rod of wood of the same thickness and about a foot in length; introduce one extremity of both rods into the fire, while the other extremities are held by the hand. When the extremity of the rod of iron which is in the fire has become red hot, the heat of the other extremity will be too great for the hand; but the rod of wood may be held in the hand till it is nearly consumed, without the least uneasy sensation. This difference arises from the difference of the conducting power in the metal and the wood.

Exper. 2.—Prepare a number of short wires of silver, copper, lead, iron, and tin, with some of glass and wood nearly of the same size and length, and coat one of the ends of each by dipping it into melted wax or tallow, and immerse the other extremity into boiling water or hot sand,—in a short time the wax or tallow will melt, first from the metallic rods in the order of their conducting power, next from the glass, and last of all from the wood.

The conducting power of metals is not in proportion to their density, as might be at first sight expected. Silver and gold possess it in the highest degree, and copper and tin are much better conductors than iron, steel, lead, or even platina, which is the densest of all metals. Liquid substances are also conductors of caloric; but it passes through them very slowly. Elastic fluids or gases possess this conducting power in a still lower degree than liquids; and hence the advantage of having double windows, a practice which is common in the construction of houses in northern climates. The stratum of air between the two windows being a bad conductor of caloric, the dissipation of the heat of the apartment is thus prevented. Of the elastic fluids, hydrogen gas has been found by experiment to conduct caloric four times better than atmospheric air.

Radiation.—Bodies raised to a higher temperature than the surrounding medium, continue to give out heat till they acquire the same temperature. This radiating power is very different in different states of the same body; and from the curious experiments of Mr Leslie, it appears that the rate of cooling is greatly influenced by the nature of the radiating surface. Polished surfaces give out heat most slowly.

Exper. 1.—Fill a globe of tinned iron with hot water, and observe the time that it requires to cool a certain number of degrees. Cover it afterwards with a thin coat of lamp black, and it will be found to be reduced to the same temperature in nearly half the time.

Exper. 2.—Prepare a canister of tinned iron of six or eight inches square, and let it be furnished with an orifice at the middle of the upper side, of about an inch in diameter, and make a small hole to receive the stem of a thermometer in the covering of the orifice. Let one of the sides of the canister remain bright, tarnish another with quicksilver, destroy the polish of the third side by scratching with sand paper, and cover the fourth side with black paint. Place the canister filled with boiling water before a concave mirror of polished tin, and fill it with boiling water. The differential thermometer is to be placed in the focus of the mirror. The nearer the canister is placed to the mirror, the greater is the effect on the thermometer; but the different sides of the canister presented to the mirror produce very different effects. The bright polished side gives out the smallest quantity of heat, and the side covered with black paint the greatest quantity. As a proof of this difference, it has been found from experiment, that while the radiating power of lamp black is equal to 100°, that of tin plate, polished gold, silver, or copper, is only equal to 12°.

These experiments furnish some excellent practical observations. When it is wished to preserve the heat of any substance confined in a metallic vessel, the surface should be kept polished and bright; and hence a silver or polished metal tea-pot retains the heat much longer than one of porcelain or earthen ware. If it be required to cool any substance quickly, the surface of the containing vessel should be painted or tarnished. Metal pipes which are employed to convey steam, should be kept polished and bright to diminish the radiating power.

3. *Effects of Caloric.*

When heat enters into combination with bodies, its effects are very different according to the nature of those bodies, or as it is more or less accumulated in them. Expansion, or the enlargement of bulk, is the most general effect; and when the accumulation is continued in some bodies, their constitution is changed, as when a solid body is converted into a liquid, and with a larger proportion of caloric a liquid is changed to the state of vapour. The composition of certain bodies is also changed by means of caloric.

Expansion.—The enlargement of the bulk of bodies when heat is accumulated in them, and their corresponding contraction when heat is abstracted, is one of its most general effects; and in all the simpler kinds of matter, these effects are uniform and invariable. This expansion, by the accumulation of caloric, takes place in the solid, the liquid, and the gaseous state of bodies.

Exper. 1.—Take a rod of iron of an inch in diameter and six or eight inches in length, and let it be exactly fitted to pass through a hole in a plate of the same metal, and to be admitted within the projecting edges of a ruler when it is cold. Expose the same rod of iron to a red heat, when it will be found to have enlarged so much in bulk, both in length and diameter, that it can neither be passed through the hole nor introduced between the projecting edges of the ruler; but when it is cooled down to its former temperature, it returns to its former dimensions.

Exper. 2.—Fill the body of a glass vessel, having a long slender neck, with spirit of wine or alcohol; immerse the body of the vessel in hot water, and the liquid will be observed to rise in the neck; and when the temperature is reduced to its former temperature, it returns to its former bulk.

Exper. 3.—If a quantity of common air be introduced into a bladder, so that it shall remain partly flaccid; by the application of heat it will be fully distended; but when it is again cooled, the air resumes its former bulk.

The amount of expansion is very different in different bodies; it is least in solids, greater in liquids, and greatest of all in elastic fluids: thus 100 cubic inches of iron, when raised from the temperature of 32° to 212°, are increased only one-tenth in bulk; 100 cubic inches of water raised to the same temperature are increased $4\frac{1}{2}$ cubic inches; and 100 cubic inches of atmospheric air raised to the same temperature are increased to $137\frac{1}{2}$ cubic inches.

The method of applying iron hoops to carriage-wheels, affords a fine illustration of the expansion of solid bodies by heat, and their contraction by cold, or the abstraction of heat. The hoop is made of rather smaller dimensions than exactly to fit the wheel. It is then made red hot, and in this expanded state it is applied to the wheel, and suddenly cooled with cold water, when it contracts and returns to its former dimensions. The expansive effect of heat furnishes an explanation of the breaking of vessels which are made of brittle substances, as glass, earthen-ware, or cast-iron, by its sudden application, or abstraction. When heat is applied suddenly, that part of the vessel which first receives the accumulation of caloric is unequally expanded, and when the vessel is of considerable thickness it never fails to be broken.

Different kinds of bodies, whether they are solids, liquids or aeriform substances, undergo different degrees of contraction and expansion, by the accumulation and abstraction of caloric. Advantage has been taken of this diversity of expansion in different metals at the same temperature, in the construction of the pendulum, on the length of which continuing always the same, depends the equable measurement of time. This is done by employing rods of different metals, the amount of the expansion of which is the same, and the rods being so arranged that they expand in opposite directions, the pendulum thus remains uniformly of the same length.

Water and some metallic substances, particularly cast-iron, when they pass from the liquid to the solid state by the abstraction of caloric, are enlarged in bulk, and thus present seeming exceptions to the general law of expansion. Water, when it is confined in close vessels and frozen, bursts them with great violence, and, it has been estimated, acts with a force equal to a pressure of more than 27,000 pounds weight. The bursting of water-pipes, the splitting of trees and rocks, and the raising of the stones of the pavement in the time of frost, is ascribed to the same expansive force in the congelation of water. To the same increase of bulk in cast-iron, when it cools, are owing the sharpness and distinctness of the lines in ornamental figures of this metal; but this increase of bulk has been properly accounted for by a new arrangement of the particles of these bodies when they assume the solid form, or to crystallization, by which a greater space is occupied than when they are in the form of liquids.

The expansion of solids is nearly equable, that is, the amount of expansion is nearly the same at the same degrees of temperature. The expansion of liquids is not equable with equal degrees of temperature. Those liquids which are most readily brought to the state of vapour expand most, and the expansion is greater the nearer a liquid is brought to that point of temperature at which it boils. At any given temperature, alcohol, whose boiling point is lower, expands more than water, and the expansion of water is greater than that of mercury. With the same addition of heat, elastic fluids undergo very nearly the same ratio of expansion.

Construction of the Thermometer.—The thermometer, an instrument of great importance in measuring the relative temperature of bodies, depends for its construction on this expansive property. The invention of this instrument is ascribed to Sanctorio, an Italian physician, who lived about the commencement of the 17th century; but it is said that it was known in Holland before his time. The thermometer of Sanctorio was a glass tube, having a hollow ball at one end, and open at the other. The air within the ball being heated, part of it is driven off, and the open end of the tube being immersed in a coloured liquid, as the air within the ball cools, the liquid rises in the tube, and is elevated or depressed as the air in the ball is expanded or condensed by the accumulation or abstraction of caloric, and thus indicates the changes of temperature to which the air within the ball is exposed. A scale of equal degrees is applied to the whole length of the tube, by which the changes may be observed. Other liquids were afterwards employed, as spirit of wine, linseed oil, and quicksilver; and the ball and part of the tube being filled with one of these liquids, the open end of the tube is closed, and thus the influence of the pressure of the atmosphere is precluded.

In the construction of Fahrenheit's thermometer, which is in most general use in this country, a small tube, of uniform width throughout, is selected, and a small ball is blown on one of the extremities. The ball and part of the tube are then filled with quicksilver, which is previously boiled to expel the air, and the open end of the tube is hermetically sealed, or closed, while the glass is softened in the flame of a lamp. The scale is next constructed. Melting

Caloric.

snow, or freezing water, is always at the same temperature. If, then, the thermometer be immersed in the one or the other it will always stand at the same point. This point is marked 32 on the scale, and is called the freezing point. The thermometer is then introduced into boiling water, and the point at which the quicksilver stands is marked 212. The intermediate space between the freezing and boiling points is divided into 180 degrees, and the same divisions are continued above the boiling point and below the freezing point, as far as the range of the thermometer extends.

Reaumur's thermometer, which was at one time generally used in France, is marked *zero* at the freezing point, and 80 degrees at the boiling point. To convert the degrees of Reaumur's thermometer to those of Fahrenheit, multiply by 9, divide by 4, and add 32.

The thermometer of Celsius, which is used in Sweden, and the centigrade of France, has the space between the freezing and boiling points divided into 100 degrees. To convert the degrees of this thermometer into those of Fahrenheit multiply by 9, divide by 5, and add 32.

The thermometer used in Russia, which is that of Delisle, is divided into 150 degrees between the boiling and freezing points. The boiling point is marked *zero*, and the degrees are reckoned downwards to the freezing point. To reduce the degrees of this thermometer under the boiling point to those of Fahrenheit, multiply by 6, divide by 5, and subtract 212; and above the boiling point, after the same multiplication and division, add 212.

Quicksilver has been selected for the purpose of thermometers, because it expands more equably than any other liquid. But even the expansion of this liquid is not perfectly equable throughout all parts of the scale. In the higher parts the expansion is greater with equal degrees of temperature.

Water exhibits a singular anomaly in its expansive property. Its greatest density is about 40° or 42°, and it continues to expand equally, whether the temperature be raised above that point or reduced under it. This curious fact, which has been a good deal investigated, yet requires explanation.

Fluidity.—All matter exists in three different states, namely, in the state of solid, liquid, and vapour, and with few exceptions it may be converted from the one to the other by the accumulation or abstraction of caloric. A mass of ice, with the addition of heat, becomes liquid, or is brought to the state of water, and if the accession of heat be continued, the whole is changed into the form of vapour; and, on the other hand, by the abstraction of caloric from a quantity of aqueous vapour, it returns to the state of water; and, being still farther reduced in temperature, becomes solid, or is converted to the state of ice. Thus, with few exceptions, it is a general law, that matter is convertible from one state to the other. Among these exceptions the air of the atmosphere may be mentioned, which always exists in the aeriform state; and spirit of wine is only known in the form of vapour and liquid, but never solid.

It is another general law in the conversion of solid substances to the state of fluids, that the change takes place, when the circumstances are the same, invariably at the same temperature. Ice becomes liquid at the temperature of 32°, and is converted into vapour at 212°.

Some bodies are instantaneously converted to the state of liquid, as water from the solid form, while others, as wax, pass through the various degrees of softness till they become quite fluid. The cause of fluidity, which was so finely elucidated by Dr Black, may be reckoned among the most beautiful and important discoveries of modern chemistry. The foundation of his doctrine is fully established by the following experiment:

Exper.—Two thin glass vessels, each containing five ounces of water, were placed in a large hall, the temperature of which was 47°. The water in one of the vessels was frozen, and in the other it was reduced to the temperature of 33°. A thermometer was placed in each vessel, and the thermometer in the water rose in half an hour from 33° to 40°, or seven degrees in the half hour. But the ice glass did not rise above the temperature of 32° till the whole of the ice was melted, which was at the end of 21 half hours, and in a few minutes afterwards the thermometer in it also rose to 40°, or eight degrees above the freezing point, and the same as in the other glass. During the whole 21 half hours the heat was absorbed by the ice, and if this absorption continued at the same rate of seven degrees every half hour, the whole amounted to seven times 21, or 147°. But this 140° was not indicated by the thermometer. It remained concealed in the water, or, being absorbed by the ice, reduced it to the liquid state. In short, this combination of caloric with the ice is the cause of its assuming the liquid form, and because it is not indicated by the thermometer Dr Black gave it the name of *latent heat*. By others it has been called *caloric of fluidity*.

The converse of this experiment proves the same thing; for as caloric is absorbed when bodies pass from the solid to the liquid state, so, on the other hand, it is given out when a liquid is converted into a solid. When water is cooled down ten or twelve degrees below the freezing point without being frozen, which may be done with a little management, by keeping the water undisturbed in a close vessel; the moment it is exposed to the air or agitated, it is changed into a porous mass of ice, and at the same time that portion of caloric which is necessary to retain it in the liquid form is given out. But this change is finely illustrated by the following simple experiment:

Exper.—Fill a phial with a saturated solution of Glauber salt, that is, add as much of the salt as boiling water will dissolve, and while it is boiling hot put in the cork tight, to exclude the air. In this state, if left undisturbed, it may be kept liquid; but after it has cooled down to the ordinary temperature of the atmosphere, if the cork be taken out, the whole becomes almost instantaneously solid, with the extrication of so much caloric as to feel sensibly warm to the hand.

The temperature at which water becomes solid is

32°, and this is called the freezing point, because water is most commonly in the liquid form in this climate. When applied to metals, because they are usually in the solid form, it is called the melting point. It is very different in different bodies, but uniformly the same in the same body. The melting point of lead is 600°, of tin 500°, of sulphur 212°, of wax 142°, of phosphorus 100°, and tallow 90°.

Vapour.—If, after the whole of a mass of ice is converted into the liquid form, or into the state of water, the application of heat be continued, the temperature rises and continues to increase till it reaches a certain point, at which the water undergoes another change. It is converted to the state of vapour, or steam, and this change is owing to the same cause which produced the conversion of the ice into water, namely, the absorption of caloric. This fact was also established by Dr Black; and, according to his experiments, a quantity of caloric absorbed for the conversion of water into steam, would have raised that water to the temperature of 800°, which, in his mode of expression, is the *latent heat* of vapour, because it is not indicated by the thermometer. This quantity is estimated higher by others, and by Lavoisier as high as 1000°.

The point at which liquids are converted into vapour is uniformly the same under the same pressure of the atmosphere. In water this point is at 212°, and it is called the boiling point. The process of boiling is nothing else than the conversion of the liquid into the state of an invisible elastic fluid or vapour. As the heat is generally applied to the bottom of the vessel, that part of the liquid which is in immediate contact with it is first changed into the form of vapour, and in its passage through the water causes the agitation or ebullition.

Some liquids assume the form of vapour at all temperatures; this is the case with water, spirits of wine, and other liquids, which are soon dissipated if they are exposed to the air in open vessels. But other liquids lose no sensible part of their bulk, till their temperature reaches the boiling point. The boiling point of ether, an extremely volatile liquid, is only 98°, of ammonia 140°, of spirits of wine 174°, of water 212°, of linseed oil, 600°, and of mercury 660°. But the boiling point of the same liquid varies with the variations in the pressure of the atmosphere. Water, and other liquids boil at a diminished temperature on the top of high mountains, or in the vacuum of an air-pump.

Exper. 1.—Boil a quantity of water in a glass vessel, furnished with a well-fitted stop-cock, and when the boiling is going on let the vessel be shut, and the application of the heat continued a few minutes, the boiling will then apparently cease, or at least the agitation will be greatly diminished. At the end of a few minutes, when the stop-cock is turned, a great quantity of steam will rush from the vessel, accompanied with a violent ebullition of the water. The steam which thus escapes is the vapour which was formed while the vessel was shut, and its gradual escape was prevented, and at the same time the agitation of the water was diminished, in consequence of that part of the vessel which is unoccupied by the water being filled with vapour, the pressure of which on the surface of the water prevents the agitation. When the vapour is permitted to escape, the temperature never rises higher than 212°, but in close vessels, as in Papin's Digester, it may be raised to 300° or 400°, in consequence of the accumulated vapour.

Exper. 2.—While the water is boiling in the vessel employed in the former experiment, if the stop-cock be shut, and the heat be withdrawn, the ebullition will entirely cease in a few minutes; let the vessel then be immersed in cold water, and the boiling will be renewed. Immerse it afterwards in hot water, and the boiling will cease. This experiment, which is called the *chemical wonder*, affords a fine illustration of the conversion of a liquid into vapour by the addition of caloric, and of the change which it undergoes in returning to the state of liquid, by the abstraction of heat. When the vessel was removed from the heat, and the stop-cock was shut, the upper part of it was filled with vapour, which, in that state, is an invisible elastic fluid. But when the vessel is introduced into the cold water this vapour is deprived of its caloric, and returns to the liquid state; the pressure is then removed from the surface of the water, and the heat which remains occasions a renewal of the ebullition; but when the vessel is immersed in hot water, the vapour expands, and, pressing on the surface of the water, causes the boiling to cease. As a farther proof of the condensation of the vapour, if the mouth of the vessel be inverted in water, and the stop-cock turned, provided it be sufficiently tight, the water will rush up with great force, and fill the vessel.

Exper. 3.—Boil three or four ounces of water in a vessel, having a communication, by means of a bent tube, with a determinate quantity of cold water in another vessel. Let the boiling be continued till the cold water is raised to the boiling temperature, and then take a quantity of water, equal to what was driven off in the state of vapour, and mix it at the boiling temperature with as much cold water as that to which the steam was conveyed. In the latter case, a slight increase of temperature only will be observed, but in the former the cold water was raised to the boiling point, thus demonstrating the latent heat of the vapour.

The cooling of bodies, by means of evaporation, also furnishes a proof of caloric being copiously absorbed by vapour. If the bulb of a thermometer be moistened with spirits of wine, or still more effectually with ether, the rapid evaporation abstracting the caloric from the mercury causes it to sink in the tube. Even water may be frozen by this process; if ether be dropt slowly on a small glass tube containing a small portion of water, the latter may be frozen in a short time. On the same principle wine is cooled either by surrounding the bottle with a wet cloth, occasionally moistening it as it dries, or introducing it into a vessel of porous earthenware, from the surface of which a rapid evaporation takes place. On the same principle, too, ice is produced in the East Indies; the water is put into shallow unglazed pans, which suffer it to oose out at the pores, and the vessels being placed on the dried stems of plants, which being bad conductors of caloric, prevent its communication with the earth. A current of air greatly promotes the process, for the vapour as it is formed is driven off, and permits a fresh portion to occupy its place. In passing through a filtering-stone, water is cooled down, not only in consequence of the evaporation from the sides of the stone, but also by the drops of water being partially converted into vapour, as they pass through the air. Of the conversion of vapour into the liquid state, the water trickling down in numerous streams on the windows and walls of crowded apartments, arising from the great quantity which is given out in breathing, and coming in contact with the cold walls and windows, furnishes a very apposite and familiar example.

Bodies decomposed by caloric.—The combination of caloric with bodies not only produces expansion and fluidity, or changes in bulk and constitution, but when compound bodies are subjected to high degrees of temperature, they are reduced to their elements, or the elements treated in the same way are formed into compounds. Thus metallic substances, which have entered into combination with oxygen, or oxides, as they are called, when exposed to a red heat, are decomposed, and a portion of the oxygen combining with caloric, appears in the form of an elastic fluid, or oxygen gas, which is a compound of oxygen and heat. When the vapour of water is passed through a tube containing iron at a red heat, the oxygen of the water combines with the iron, and forms an oxide, while the hydrogen passes off. If the vapour of ammonia be passed through a red hot tube, it is resolved into its constituents, hydrogen and azote, which, having united with caloric, appear in the form of gas; and if hydrogen and azotic gasses be passed through a red-hot tube, they enter into combination, and are converted into ammoniacal gas.

Quantity of caloric in bodies.—The researches and speculations of chemical philosophers who have occupied their attention in ascertaining the quantity of caloric in bodies, are directed to two objects, one of which is to determine the absolute or entire quantity which exists in any body, and the other is to discover the relative proportion which different bodies require to raise them to the same temperature. The speculations on the first point have not been attended with much success, and do not seem to be practically useful. The specific caloric of bodies can be more satisfactorily explained.

It might appear at first sight that the same quantity or bulk of different kinds of matter might be brought to the same temperature by the accesion or abstraction of equal quantities of caloric. But the case is quite different; for different bodies require different quantities of caloric to raise them to the same temperature.

Exper. 1.—Take one pound of water, at the temperature of 100°, and mix it with another pound of water at the temperature of 50°, the acquired temperature of the mixed quantities of water will, in a short time, be the mean between 50 and 100°, for the pound of water at the higher temperature will give out 25°, and the pound of water at the lower temperature will receive 25°, and the mixture will be at the temperature of 75°.

Exper. 2.—Take a pound of water at 100°, and a pound of mercury at 50°, and mix them together, the medium temperature in this case is not obtained, but is reduced only to 88°, and therefore the water has lost only 12°, while the mercury has gained 38°.

Exper. 3.—Take one pound of water at 50°, and a pound of mercury at 100°, and when they are mixed together the temperature will be only 62°, for the mercury gives out 38°, and the water receives only 12°. This experiment shews clearly that different quantities of caloric are necessary to increase or diminish the temperature of different bodies, for the quantity which raises water 12°, raises mercury no less than 38°. This is called the *specific caloric* of bodies. This difference in bodies is also denoted by the term *capacity for heat*; and the body which requires the greater quantity of caloric to raise it to the same temperature, is said to have a greater capacity for heat.

A few examples of the specific caloric of bodies may be given. These are compared with the specific caloric of water, which is reckoned 1.000. The specific caloric of hydrogen gas is 21.4000; of oxygen gas, 4.7460; of common air 1.7900; of common salt, dissolved in 8 parts of water, 0.832; of muriatic acid, 0.6800; of oak, 0.51; of quicklime, 0.2199; of iron, 0.1264; and of lead, 0.0424.

Cold.—The term *cold*, strictly speaking, is the abstraction of a quantity of heat, or is expressive of the relative temperature of two bodies. If the hand be held in water at the temperature of 100°, for a few minutes, and then suddenly immersed into another portion of the same liquid at the temperature of 40°, the latter is said to be *cold*, a term which is obviously expressive of the sensation excited in the body. This is easily illustrated by experiment.

Exper.—Take three quantities of water, the first at the temperature of 33°, or 34°, the second at the temperature of 50°, and the third at the temperature of 100°. Put the right hand in the water at the highest temperature, and the left into the water at the lowest, and having kept them for a minute, suddenly immerse both hands in the water at the temperature of 50°, the water will feel cold to the right hand, and warm to the left hand; and thus the same body produces different sensations, while it is at the same temperature, arising from the previous state of the hands, and the absorption of caloric by the one, and its abstraction by the other.

Before the modern doctrines of the absorption and abstraction of caloric were fully established, cold was considered as a distinct body, and not as a term expressive of the absence of some other body, and frigorific particles were as familiarly spoken of as the particles of any other matter. This opinion received some support from the experiments of M. Pictet of Geneva, in which cold seemed to be reflected.

Exper.—Two concave mirrors of tinned iron were placed at the distance of $10\frac{1}{2}$ feet from each other; a thermometer was placed in the focus of the one, and a glass vessel full of snow was placed in the focus of the other; the thermometer sunk several degrees; when the snow was removed it rose again, and when a greater degree of cold was produced on the snow by pouring an acid upon it, which dissolved it rapidly, the thermometer fell several degrees lower. From these appearances it has been supposed that the cold given out by the snow is reflected by the mirrors, and causes the fall of the thermometer; but in this case the thermometer having a higher temperature than the snow, may be considered as the heating body; and on the principle of the equal distribution of caloric going on among bodies at different temperatures, till they reach the same degree, the interchange of the heat in the thermometer, and the snow, is greatly facilitated by the favourable circumstances in which they are placed.

Freezing mixtures.—Great degrees of cold are artificially produced by mixing together those substances which dissolve rapidly. The conversion of a solid to the liquid state, it will be recollected, is owing to the absorption of caloric, and when this process proceeds rapidly, a great diminution of temperature may be produced. In the production of artificial cold, mixtures of the neutral salts dissolved in water are generally made, or of diluted acids with some of the neutral salts, or of snow or pounded ice, with some of the same salts. A mixture of five parts of sal ammoniac, five parts of nitre, and sixteen parts of water at 50°, reduce the temperature to 10°. The same proportions of sal ammoniac, nitre, and water, with the addition of eight parts of Glauber salt, produce a degree of cold equal to 4°. Glauber salt eight parts, and muriatic acid five parts, reduce the temperature from 50° to 0°. Equal parts of snow and common salt, reduce the temperature from thirty-two to 0°. Three parts of muriate of lime, with two parts of snow, reduce the temperature from 32° to 50° below 0°; and two parts of muriate of lime, with one of snow, reduce the temperature from 0° to 66° below it. A full account of freezing mixtures may be seen in Mr Walker's Memoirs, in *Phil. Trans.* for 1795 and 1801.

When these substances are to be employed as freezing mixtures, the salt should be fresh crystallized and reduced to fine powder, and the different ingredients should be separately cooled down to that degree from which the lower temperature is reckoned. Thus, if it be the object to freeze mercury, and if muriate of lime and snow be employed for that purpose, a mixture of three parts of muriate of lime, and two parts of snow, being reduced by some other freezing mixture to the temperature of 32°, or some degrees below it, another portion of the same ingredients in separate vessels may be cooled down to *zero*. These materials being speedily mixed together, will produce a temperature equal to 50° below *zero*; and at the temperature of 40°, mercury becomes solid.—Vessels of tin-plate, or such as are the best conductors of caloric, are employed in these processes; and when acids are used, they may be lined with a coating of wax; the vessel should be of no larger dimensions than what is sufficient to contain the materials.

4. *Sources of Caloric.*

Five different sources of caloric have been enumerated according to the nature of the powers from which it is derived, or the means by which it is evolved, namely, the sun, combustion, percussion, friction, and mixture.

1. *The Sun.*—The great source of light and heat in our planetary system, is the sun. The speculations of philosophers have been occupied in considering the constant waste of light and heat to which the sun must be subjected. It has been calculated that at the rate of two grains a day the diameter of the sun would be shortened ten feet in 6,000 years. But, according to the observations of Dr Herschel on the nature and constitution of the sun, it appears that the body of the sun is opaque, that he is surrounded with an atmosphere like that of the earth, and that this latter is surrounded by a luminous atmosphere, from which are emitted all the light and heat, which were supposed to proceed from the body of the sun. In consequence of changes which seem to be constantly going on in this luminous atmosphere, it exhibits different degrees of splendour; and during these variations, the difference in the quantity of light and heat given off is very great; and to these changes Dr Herschel ascribes the average difference of temperature in different seasons, and the consequent abundance or deficiency of the crops.

The rays of light, as well as those of caloric, are more copiously reflected from white surfaces, than from those of a deeper colour. The rays enter the opaque body, combine with it, and increase the temperature, but they pass through transparent bodies. The absorption of caloric by opaque substances is illustrated by the following experiments.

Exper. 1.—Take four pieces of cloth of the same size, but of different colours, as black, blue, red, and white; expose them on a surface of snow to the sun's rays, and after they have remained for some time in this situation, it will be found that the black has sunk deepest, the blue nearly to the same depth, the red to a less depth, and the white scarcely at all. In this experiment, which was first made by Dr Hooke, and afterwards by Dr Franklin, the pieces of cloth sink into the snow in consequence of the caloric which they absorb from the sun's rays, and the effect is greatest in those which are of the darkest colour, while the whole of the caloric as well as light is reflected by the white cloth. The common experience of black clothes being warmer, and the practice of light coloured garments being worn by the inhabitants of warm climates, are illustrations of the same fact.

Exper. 2.—Sir H. Davy prepared six similar pieces of copper, each one inch square, and about two lines in thickness, and painted them of different colours, of white, yellow, red, green, blue, and black. A thin layer of cerate, composed of oil and wax, which melted at 76°, was attached to the under surface. They were placed on a board painted white, and the upper surfaces were exposed to the sun. The cerate on the black plate melted first, the blue next, the green and red followed, and the yellow last; but the white was scarcely affected when the black was in complete fusion.

Berard's experiments.—The experiments of Berard, an account of which was laid before the French Institute in 1813, lead to conclusions somewhat different from those of Dr Herschel, concerning the effects of solar light. He found the heating power increased from the violet end of the spectrum to the red ray, and it was greatest at the very extremity of the red ray; but beyond it the thermometer was only one-fifth above the temperature in the surrounding air of what it had been in the red ray itself; and the absolute intensity of the heat was less than in Dr Herschel's experiments.

The two spectra produced by transmitting a pencil of rays through a prism of Iceland spar, exhibited the same properties. In both, the heating power diminished from the violet to the red end, and ceased nearly beyond the last visible red rays. But the luminous particles being polarized by the crystal in this operation, Berard attempted to discover whether the invisible rays of heat experienced the same effect. To ascertain this point, he received the solar ray upon a polished transparent glass, which polarized or directed a portion of it by reflection. This reflected ray was received upon a second glass fixed in an apparatus, which permitted it to be moved in the ray under a constant incidence, the incidence itself being so determined that in a certain position of the glass the reflection ceased to take place. The heating and luminous rays being collected with a mirror, reflected from the second glass, and directed upon a thermometer, he found that as long as light was reflected, the thermometer rose, from which he concluded that heat must be reflected likewise; but when the light was totally transmitted, the transmission of the heat took place at the same time, for the thermometer was not affected.

In another experiment, in place of the ray of solar light, he substituted a ray of radiant heat, proceeding from a body hot but not luminous, and the same effect followed; for the thermometer rose when the second glass was so situated as that it would have reflected light, and it did not rise when the second could not have reflected light. From these experiments he concluded that the heating principle never separates from the luminous particles; and that the particles of invisible radiant heat are modified by reflection precisely like light.

To determine the chemical effects of the differently coloured rays, pieces of card impregnated with muriate of silver, or small phials filled with a mixture of oxymuriatic and hydrogen gases, were successively subjected to their action, from which the power of each might be seen by the intensity or rapidity of the chemical change; and it was found, that the chemical intensity was greatest at the violet end of the spectrum, and that it extended a little beyond that extremity, but continually decreased as it approached to the indigo and blue rays.

Having concentrated, by means of a lens, that part of the spectrum which extends from the green ray to the extreme violet, and by means of another lens all that portion which extends from the green ray to the extreme red; and although the last pencil formed a white point, so brilliant that the eye could scarcely bear it, yet the muriate of silver exposed for two hours to this brilliant light, exhibited no perceptible change; while, after being exposed to the other pencil, greatly inferior in brightness and in its effects on the thermometer, it was blackened in less than six minutes. From these experiments he concluded, that the chemical effects produced by light are not owing to the heat combining with the substance of the body, because, on such a supposition, the faculty of producing chemical combination would be greatest in those rays which have the greatest heating power.

The hypothesis which Messrs Berthollet, Chaptal, and Biot, who presented the report on the curious memoir of Berard to the Institute, seem disposed to adopt, is, that light is composed of a collection of rays unequally refrangible, and of course unequally acted upon by bodies. This view supposes original differences in their size and velocity, or in their affinities; and hence it would appear, that the chemical, colorific, and calorific, or heating effects of light, depend on the difference of force of the homogeneous power producing the sensations and effects of light. The power of producing vision is confined within certain mean limits; too little, or too much refrangibility, renders it incapable of producing that effect; and the heating and chemical faculty varies through the whole length of the spectrum, in the same degree with the refrangibility, but in contrary proportions.

2. *Combustion.*—The remarkable appearances which are exhibited in the process of combustion, the changes induced on the substances employed, and the important results which are obtained, could not escape notice, and could not fail to excite great interest and attention. As combustion is one of the principal sources of heat, it has long occupied the attention of chemical philosophers, both with regard to the means of improving the process in the arts of life, and to the discovery of a theory capable of affording a satisfactory explanation.

When a piece of iron is exposed to a high temperature it becomes red hot, and during this change it has absorbed both light and heat; for when it is removed from the fire, it continues for some time to give out both: but when it is cool it does not appear to have undergone any perceptible change, and the same process may be often repeated. If a piece of wood be treated in the same way, light and heat are also given out; but it is totally changed—the greater part is dissipated or passes off in the form of elastic fluids, and a small portion of ashes only remains. Sulphur raised to the temperature of 300° or 400°, enters into new combinations; and metallic substances, when subjected to different degrees of heat, are completely changed. Instead of possessing great tenacity and metallic lustre, they are generally reduced to the state of powder.

None of these changes can take place without atmospheric air or oxygen gas, which is one of the constituents of that elastic fluid; and in all cases of combustion, oxygen gas disappears or changes its constitution. Light and heat are emitted, and the combustible acquires new properties. In considering the phenomena of combustion, it has been always a question what share in the process is to be ascribed to the different agents which are necessarily concerned, and from what source the light and heat are derived. In one point, it is generally agreed, that the heat is given out by the oxygen gas, and it is that portion of caloric which is necessary to retain it in the elastic form. But different opinions have been held with regard to the source from which the light proceeds.

Among the alchemists, sulphur was regarded as the universal inflammable principle; and all bodies susceptible of combustion were supposed to contain a portion of that substance. Becher rejected that opinion, and admitted that sulphur contained the inflammable principle, but was not the principle itself. This theory was greatly improved by his pupil Stahl, who gave the inflammable principle the name of *phlogiston*, and hence arose what was long known by the appellation of the Stahlian or Phlogistic theory.

According to the theory of Stahl, phlogiston is supposed to exist in all combustible bodies, that is, in all bodies that can be burnt, and it is supposed to be the same in all. The diversity of appearance of combustion in different bodies is ascribed to their other elements, with which the common principle of inflammability or phlogiston is combined. Inflammation or combustion, is the gradual separation or dissipation of this principle, and then the body from which it has been separated is no longer combustible till it again combine with it.

These opinions prevailed about the middle of the 17th century, when Dr Hooke proposed a theory that air is the universal solvent of all combustibles; and this solution takes place when the temperature is raised. This solvent substance is said to be similar to that which exists in nitre or salt-petre. Pursuing this opinion, Mayow of Oxford introduced the denomination of *nitro-aërial particles*, which were necessary in combustion, and which, as the name indicates, exist in nitre. The phenomena of combustion, according to this theory, depend on the motion of these particles; and when the motion is rapid, light and heat are given out.

In the progress of chemical science, the imaginary principle of phlogiston was called in question. It was observed that substances exposed to the rays of the sun became inflammable; and having in this way acquired the principle of inflammability, phlogiston was supposed to be the same as light, or it was light fixed in bodies. It was observed, too, that the air in which a body is burnt is completely changed, and this change was ascribed to its combination with phlogiston; and hence the terms *phlogisticated* and *dephlogisticated*—the first denoting air combined with phlogiston, and unfit for supporting combustion; and the second expressive of pure air. In another step of the progress it was supposed that light and heat exist in the air; and during combustion the phlogiston combines with the air, while the light and heat are separated. According to another opinion, hydrogen is the principle of phlogiston; and the process of combustion is the combination of this principle with oxygen. Some other modifications of this theory were adopted, till it appeared that the combustible substance and oxygen gas were only concerned in the process. According to the views of Lavoisier, who first proposed the theory, and by whose name it was known, the light and heat are in combination with the oxygen in its elastic form, and the oxygen combining with the solid during combustion, the light and heat are separated. This theory has been also modified by later philosophers; and while they admit the oxygen gas to be the source of the heat, in consequence of its fixation in the body which has undergone the process of combustion, they suppose that the light is derived from the combustible.

In the process of combustion three modifications are distinguished, namely, *ignition*, *inflammation*, and *detonation*. The difference of effects observed in these modifications, seems to depend on the nature of the substances which undergo the change.

Ignition.—When a metallic substance, as a piece of iron, is exposed to a high temperature, it becomes red hot, and is said to be in a state of ignition—light and heat are given out; but when it is cooled, it returns to its former state without any perceptible change. But this is not to be considered as a true case of combustion. When a mass of iron is subjected to a still higher temperature, it is said to be in a state of incandescence or white heat.

Inflammation.—This modification of combustion is partly owing to the strong affinity of the body for oxygen, and partly to the slight affinity which exists between the particles of the combustible body. The burning of a candle or of sulphur, in the open air, affords familiar examples; but the same substances exposed to combustion in oxygen gas exhibit a more marked and more brilliant inflammation.

Detonation.—The third modification of combustion is detonation, in which an instantaneous inflammation, accompanied with explosion, is produced. This effect arises either from the sudden evolution of elastic fluids from the solid state, or from the sudden condensation of elastic fluids into the liquid state. Of the first, the explosion of gunpowder, in which an immense volume of elastic vapour is instantaneously formed, is a good example; and the inflammation of oxygen and hydrogen gases, which is attended with a violent explosion and great condensation, with the extrication of light and heat, is an instance of the last.

Products of combustion.—The result of all the processes of combustion is the formation of water, of an acid, or an oxide; when oxygen and hydrogen enter into combination, water is produced; when oxygen unites with sulphur, carbone, or phosphorus, the product is an acid; and when it enters into combination with metallic bodies, the new compound is called an oxide.

3. *Percussion.*—When two hard bodies, as in the case of flint and steel, are struck against each other, heat is given out. A piece of iron, by continued hammering, can be brought to a red heat. This production of heat, or increase of temperature, has been ascribed to the condensation of the particles. It is well known that the condensation or compression of air, produces so high a temperature, that combustible matters may be set on fire; and in the experiments of Dessaignes, it appears that not only air but liquids and solids give out both light and heat by sudden compression.

In some cases, bodies which are incombustible give out light and heat by percussion. Two hard stones produce this effect when they are struck against each other. The particles that are thrown off are raised to a high temperature, and brought to a state of fusion, owing perhaps to the condensation of the minute particles which are separated, but no actual combustion has taken place.

Oxygen Gas.

4. *Friction.*—A great deal of caloric is given out by friction. The intensity varies according to the nature of the substances employed, and the time that the friction is continued. When combustible substances are operated upon, they are set fire to; and the temperature of incombustible matters is raised so high, as to communicate fire to combustible bodies. When heat is produced by friction, the effect cannot be ascribed to an increase of density; for a great degree of heat is produced by rubbing the hand on a piece of soft cloth,—and even the waters of the ocean, when strongly agitated in a storm, indicate a rise of temperature. The heat produced by friction has been ascribed by some to a change in the specific caloric of bodies.

In the construction of machines it is of no small importance to select proper kinds of wood, because it has been found that different woods operating on each other by friction produce very different degrees of heat; and when the friction is continued in the direction of the fibres, a greater degree of heat is generated.

5. *Mixture.*—It is one of the characteristics of chemical action to produce a change of temperature; and this, it is obvious, arises from a change of bulk. When a body passes from the solid to the fluid state, it absorbs caloric; and when it changes from a fluid to a solid, it gives out heat. When ammonia and muriatic acid, in the state of gas, are combined together, a solid is formed, and heat is given out. Nitrous gas and oxygen gas united together form a liquid, which is also accompanied with the evolution of caloric. Similar effects are obtained by mixing two liquids, as, when sulphuric acid is added to water, the temperature may be raised as high as the boiling point of water. Heat is also given out when solids and liquids combine. Water poured upon well burnt limestone becomes solid, with a copious extrication of heat; and when the process is conducted in the dark, it appears that light is also emitted.

Electricity.—In many of their effects, electricity and galvanism, which are considered as modifications of the same power, have an obvious analogy to light and heat. Subjected to the action of these powers, bodies acquire a very high temperature; compounds are reduced to their elements, and the elements are brought into new combinations. Whether it be that a higher temperature is induced in the operation of electricity and galvanism, or whether it arise from any peculiar activity in these powers, the effects produced are in a much higher degree than can be obtained by the greatest artificial heat; and substances have been decomposed by means of galvanism, which the highest temperature yet attained could not effect. But although the history and effects of electricity and galvanism might, with no impropriety, be investigated in their general connection with light and heat, yet it would be an anticipation of the necessary detail of that department of science, which must be introduced under its proper head. See Electricity.

Chap. III. Of Oxygen Gas.

The word *oxygen* is composed of two Greek words, which signify *to make sour*, because, according to the chemical language proposed by the French philosophers, the base of oxygen gas is considered as the acidifying principle, that is, the base of oxygen gas, entering into combination with the various substances, forms an acid, as with sulphur, sulphuric acid, and with carbone, carbonic acid. Oxygen gas, or its base, oxygen, is one of the most important elements in chemical processes. It was discovered by Dr Priestley in 1774, and, from the prevailing theory, was denominated *dephlogisticated air*. It was called empyreal air, vital, and highly respirable air, by others.

Preparation.—Oxygen gas may be obtained by exposing to a red heat, red lead, or the red oxide of mercury, and collecting the gas as it passes off in vessels filled with water, and inverted on the shelf of the pneumatic trough. Nitre, or salt-petre, exposed to a red heat in an earthen ware or coated glass retort, also furnishes oxygen gas. It may be obtained likewise by introducing into a glass retort a quantity of the black oxide of manganese reduced to powder, adding an equal weight of sulphuric acid, and applying a moderate heat; but oxygen gas is most conveniently and most copiously procured by subjecting the black oxide of manganese, in an iron retort, to a red heat. By fitting a bent iron tube to the retort, by accurate grinding, or securing it with a lute, to prevent the escape of the gas, it may be collected in the usual way over water.

Process explained.—The black oxide of manganese is a compound of the metal and oxygen. When this compound is exposed to a high temperature, the force of affinity between a large proportion of the oxygen and the manganese is destroyed, and the matter of heat, or caloric, combines with the oxygen; a new compound is formed, and oxygen gas, an elastic fluid, appears. The nature of the process is the same when red lead, or the red oxide of mercury, is employed. Manganese combines with oxygen in two proportions; but sulphuric acid can only unite with the oxide of manganese in its lowest proportion; the other portion of oxygen gas is consequently separated when the sulphuric acid is added to a quantity of manganese; and as the acid in its new combination becomes solid, the caloric, which retained it in the liquid form, combines with the separated oxygen, and oxygen gas is obtained. This process furnishes an example of double affinity. When oxygen gas is obtained from nitre, the nitric acid, one of its constituent parts, is decomposed, and its oxygen appears in a separate form; but other elastic fluids are evolved at the same time, so that the oxygen gas prepared in this way is less pure than when it is obtained from manganese and some other substances.

Properties.—In its mechanical properties, oxygen gas resembles common air and other elastic fluids. It is invisible, colourless, and susceptible of indefinite expansion and compression, has neither taste nor smell; it is 740 times lighter than its bulk of water, and 100 cubic inches at the temperature of 60°, and, when the barometer stands at 30 inches, weigh about 34 grains. No perceptible quantity of oxygen gas combines with water. Combustible substances burn with greater rapidity and brilliancy in this gas than in common air, and animals live much longer by respiring a determinate portion of it. Oxygen gas is not less necessary for the germination of the seeds of plants.

Exper. 1.—Introduce a quantity of oxygen gas into a small jar or wide mouthed bottle, and let down into this vessel a lighted wax taper, or a splinter of wood in a state of inflammation, it will burn with great splendour till the oxygen gas is expended; and if the taper be blown out and again immersed in the vessel while any part of the wick is red hot, it re-kindles with a slight explosion.

Exper. 2.—Fasten a piece of charcoal to a copper wire, make the end of the charcoal red hot, and introduce it into a jar of oxygen gas, and beautiful sparks will be thrown off during the combustion.

Exper. 3.—Melt a quantity of sulphur in a small brass cup, and continue the heat till it is inflamed; in this state immerse it in a jar of oxygen gas, and a very rapid combustion, with a copious effusion of white light, will take place.

Exper. 4.—Put a small bit of phosphorus in a similar brass cup, set fire to it with a heated wire, and introduce it into a vessel of oxygen gas; the combustion proceeds with great rapidity, and the blaze of light is too splendid for the eye to bear.

Exper. 5.—Coil a piece of small iron wire round a glass rod, and having slipped it off suspend it in the spiral form from the end of a cork; to the other extremity of the wire fix a bit of thread, or a small bit of wood, and having dipped it in wax or melted sulphur, set fire to it, and immerse it in a jar of oxygen gas. The wire will burn with great brilliancy, and continue to throw off sparks till the whole is consumed, or the gas is exhausted. In this experiment the red hot globules of the iron as they drop on the bottom of the vessel are apt to fracture it. But this accident may be prevented by pouring in a little sand to form a layer at the bottom of the vessel. When the wire is very small the red hot globules are thrown off laterally, and produce the same effect on the sides of the vessel. The use of thicker wire is the best precaution against this accident.

Exper. 6.—Let a jar having a neck and opening at the top, furnished with a ground glass stopper, be filled with oxygen gas, and having suspended the brass cup by means of a wire from the end of the glass stopper, put a little sulphur in the cup, and having inflamed it as in the former experiment, introduce it into the jar, and secure the stopper tight in its place. The combustion will go on with great brilliancy, till the whole of the sulphur or the gas is consumed. During this process, the water will rise in the inside of the jar, and when the air has cooled will rise still higher, affording a proof that the confined oxygen gas, or part of it, has disappeared, or has assumed a different form.

These experiments furnish ample evidence of the remarkable property of oxygen gas supporting a more brilliant combustion than common air. This arises from its strong affinity for the combustible body. The last experiment shews that it has entered into some new form; and the same thing would have appeared in the other experiments, if they had been conducted in the same way, excepting in the combustion of charcoal; the product obtained, which is carbonic acid, is nearly of the same bulk with the oxygen gas which has entered into the new combination. The sulphur and phosphorus which undergo combustion in oxygen gas, are converted into acids which appear in the liquid form, and the iron in its new combination is changed to the state of oxide.

Oxygen gas forms one of the constituent parts of atmospheric air, and the processes of combustion and respiration depend entirely on the proportion of this gas with which it is combined.

Chap. IV. Of Azotic Gas.

The word *azote*, or the base of azotic gas, is of Greek origin, and is expressive of its unfitness for the support of animal life.

Preparation.—Azotic gas may be obtained by taking a quantity of muscular flesh, or the fibrous part of the blood, and after being well washed, cut it into small bits, put it into a retort or a matrass, with a ground tube, and pour over it diluted nitric acid, exposed to the heat of about 100°, and collect the air as it escapes through the tube in proper vessels in the pneumatic apparatus. If the substance called sulphuret of potash be exposed to a determinate quantity of the air of the atmosphere enclosed in a bell glass over water, or if sulphuret of iron be formed into a paste with water, and treated in the same way, in the course of a few days the air within the glass is diminished, and what remains is azotic gas. Phosphorus exposed to the action of a confined portion of atmospheric air, also abstracts the oxygen and leaves the azotic gas behind.

Properties.—Azotic gas possesses the mechanical properties of common air; 100 cubic inches at mean temperature and pressure, weigh nearly 30 grains; it is altogether unfit for the support of combustion or of respiration; and it is absorbed only in small proportion by water.

Exper. 1.—Introduce a lighted taper into a jar filled with azotic gas, and the moment that the flame comes in contact with the gas it will be extinguished.

Exper. 2.—Prepare two jars, one of which is filled with oxygen gas and the other with azotic gas; immerse a lighted taper in the azotic gas, and the moment it is extinguished, plunge it into the oxygen gas and it will be rekindled, with an explosion, as in a former experiment. The same may be repeated several times, the taper will be extinguished in the one, and lighted up in the other.

Azotic gas is to be considered as a compound of its base, azote, and caloric, on which it depends for its elastic form; but it enters into combination with oxygen, and affords several very important compounds.

Sect. I. *Atmospheric Air.*

Common air, as it is called, or the air of the atmosphere, is a compound of oxygen and azotic gases. If a mixture of about four measures of azotic gas, and one of oxygen gas, be prepared, the product resembles atmospheric air in all its properties, and is equally fit for the support of combustion and respiration. The proportions of the two gases in atmospheric air are, 79 of azotic gas and 21 of oxygen gas by bulk; or by weight, 74 of azotic

Azotic Gas.

gas and 26 of oxygen gas. These proportions are uniform and constant in all parts of the world, in the coldest and the warmest climates, in places where the air is supposed to possess the highest salubrity, as well as in places where a great deal is consumed in the processes of combustion and respiration, and where it might be expected to be diminished in purity. This uniformity of the proportions of the constituent parts of the atmosphere, presents a decisive proof that it is to be considered as a chemical compound. The weight of 100 cubic inches of atmospheric air is about 31 grains; it is about 816 times lighter than an equal bulk of water, at the temperature of 60°, and when the barometer stands at 30 inches, and the pressure of the air of the atmosphere is nearly equal to fifteen pounds on every square inch.

The processes of combustion and respiration are supported by the air of the atmosphere only in proportion to the oxygen gas which it contains.

Exper.—If a quantity of common air be confined in a jar which is furnished with a ground stopper, and if phosphorus, in a state of inflammation, be introduced, as in a former experiment, the combustion will be much less brilliant than in the oxygen gas, and will cease entirely when about one-fourth of the air within the jar is consumed, as will appear from the the water rising to that height in the inside.

Sect. II. *Nitrous Oxide Gas.*

Preparation.—If a quantity of the salt called nitrate of ammonia be put into a glass retort, and heat applied between the temperature of 340° and 500°, the salt melts, and after it has become liquid it gives out a great quantity of white fumes, which may be received in jars over water. After standing for some time the gas becomes quite transparent; in its physical properties it resembles common air; 100 cubic inches weigh nearly 49 grains, and its constituent parts are 63 parts of azotic gas, and 37 of oxygen gas.

The taste of this gas is sweetish, and the odour is agreeable; water absorbs more than half its bulk and acquires a sweetish taste; and by boiling, the whole of the gas may be expelled unchanged.

Some combustible bodies burn nearly with the same brilliancy as in oxygen gas, but they must be in a state of ignition before they are introduced. A burning taper at first exhibits a splendid white light, and as the process advances the flame gradually lightens. The combustion of phosphorus is little inferior to the same process in oxygen gas.

Effects when respired.—When this gas is respired, its effects on the nervous system are in some degree analogous to those of intoxicating liquors; highly pleasureable feelings are induced; a peculiar thrilling sensation diffused over the whole frame is experienced; and hence it has been denominated *Gas of Paradise.* On different constitutions its effects are different, and although it may be respired for three or four minutes with impunity, yet it is unfit for the support of animal life.

Sect. III. *Nitrous Gas.*

Preparation.—If a quantity of copper-wire or copper-filings, or other metal, be put into a retort, and diluted nitric acid be added, a violent action takes place, and a great quantity of gas, which may be collected in jars over water, is evolved. This is nitrous gas. In this process the nitric acid, which is a compound of nitrous gas and oxygen, is partially decomposed; a portion of the oxygen combines with the metallic substance and forms an oxide, and another portion of the acid unites with this oxide, forming a neutral salt, while the nitrous gas, combining with the caloric that is given out during these changes, passes off in the form of elastic fluid. Nitrous gas was known to Dr Hales, but the examination of its properties was prosecuted by Dr Priestley.

Hydrogen Gas.

Properties.—Nitrous gas is an elastic, colourless fluid, without any sensible taste, produces no change on vegetable blues, which is the test of acidity; 100 cubic inches weigh 34.26 grains; it consists of nearly 56 parts oxygen, and 44 parts of azote; and it is altogether unfit for respiration.

Some combustible substances burn in nitrous gas, but others are extinguished. The combustion of phosphorus in a state of active inflammation, is almost equally brilliant as in oxygen gas; and Homberg's pyrophorus, a substance which inflames spontaneously in the open air, becomes instantly red, and burns very vividly. In these processes the oxygen of the nitrous gas combines with the combustible, and azotic gas remains behind. Water absorbs from one-tenth to one-twentieth of its bulk of this gas at the common temperature, but when it is boiled or frozen the gas separates unchanged.

Exper. 1.—To a jar of nitrous gas over water add slowly and in repeated portions a quantity of atmospheric air; when the two gases unite, a red colour appears, the bulk is diminished, and heat is evolved.

Exper. 2.—Instead of atmospheric air, let a quantity of oxygen gas be admitted to the jar of nitrous gas, a similar diminution of bulk will follow every addition of the gas; and if too great a proportion of oxygen gas be not introduced, the whole will be converted into the state of liquid.

In these experiments the nitrous gas combines with another portion of oxygen, and is converted into nitrous acid, which, as it assumes the state of liquid by the condensation of the two gases, gives out heat.

The compounds of oxygen and azotic gases present a fine illustration of the effects of chemical combination, in the diversity of products obtained by the different proportions of the two constituent parts. In 100 parts of atmospheric air there are 26 by weight of oxygen gas, and this affords a compound with azotic gas, which is not only salutary, but absolutely necessary for the support of animal life; when the proportion is increased to nearly 37 parts of oxygen gas, the compound, nitrous oxide, may be respired for a short time without injury, but when it is increased to 56 or 70 parts, as in nitrous gas and nitrous acid, the compounds have acquired properties which render them noxious to animal life, producing instant suffocation when they are respired.

Chap. V. Of Hydrogen Gas.

The name of this gas, derived from the Greek, indicates that it is one of the constituent parts of water; its combustible property is noticed in the writings of some of the older chemists, and in 1766 its properties were particularly examined by Mr Cavendish.

Preparation.—Put a quantity of iron filings, or granulated zinc, into a glass retort, and add sulphuric acid, previously diluted with 5 or 6 times its bulk of water; a violent action takes place, with the extrication of a great quantity of elastic fluid, which may be collected in jars over water. This is hydrogen gas, or, as it was formerly denominated, *inflammable air*.

In this process various chemical affinities are brought into action. The sulphuric acid combines with the metal, and forms with it a neutral salt; but the metal must be previously in the state of oxide, and it derives its oxygen from the water, while the hydrogen, the other constituent element of the water, uniting with the caloric which is separated in some of these changes, appears in the form of elastic fluid or hydrogen gas.

Properties.—Hydrogen gas possesses the same physical properties as common air, but it is the lightest of all gaseous substances; one hundred cubic inches, at mean temperature and pressure, weigh only about two grains and a quarter; it is unfit for respiration and for the support of combustion, and it has no perceptible taste, but the odour is peculiar, and somewhat disagreeable. Hydrogen gas is but slightly absorbed by water.

Exper. 1.—Fill a jar with hydrogen gas, and apply a lighted taper to its mouth, the gas will take fire with a slight explosion where it is in contact with atmospheric air, and will continue to burn with a lambent flame till the whole is consumed. The combustible property of the gas is illustrated by this experiment.

Exper. 2.—Immerse suddenly into a tall jar filled with hydrogen gas a burning taper; the gas will be kindled at the surface, but the taper, as it is plunged deeper, will be extinguished, affording a proof that this gas is unfit for the support of combustion. The same thing may be shewn by suddenly inverting a jar filled with hydrogen gas over a burning candle, which is immediately extinguished.

Exper. 3.—Fill two jars with the gas, keep the one in an inverted position, and hold the other with its mouth upwards for a few minutes; if a lighted taper be applied to each of the jars, it will be found that the whole of the gas has escaped from the latter, but not from the former, in consequence of its being so much lighter than the air of the atmosphere. The low specific gravity of this gas renders it peculiarly proper for filling air-balloons, for which purpose it is employed. In the common way of procuring hydrogen gas it is about 7 or 8 times, but when pure 12 or 13 times, lighter than the same bulk of atmospheric air.

Sect. I. *Water.*

In the progress of chemical science in modern times, various opinions were held, both by French and British chemists, of the nature of the product obtained by the combustion of oxygen and hydrogen gases. The experiments of Mr Cavendish, which were made about the year 1781, led to the conclusion that water is the result of this combustion; and this was finally confirmed by the experiments of Lavoisier, and his associates, which were conducted on a very large scale. This fortunate discovery may be considered as one of the most important in the whole range of chemical science.

The proportions of the two elements which enter into the composition of water, are two parts of hydrogen to 15 of oxygen by weight, or two of hydrogen to one of oxygen by bulk. These proportions have been ascertained by experiment.

Exper. 1.—If two measures of hydrogen gas and one measure of oxygen gas be introduced into a phial, and set fire to, a violent explosion is produced; and if the experiment be made over mercury, the gases disappear, and water is formed. When the gases are exploded in a phial held in the hand, it ought to be wrapt round with a towel, and firmly grasped with both hands, by which all danger from the bursting of the phial is precluded.

Exper. 2.—If a similar experiment is made with atmospheric air, in place of oxygen gas, the oxygen gas of the air disappears, and the azotic gas remains behind.

Exper. 3.—If the vapour of water be passed through a red-hot gun barrel, or a porcelain tube, with a quantity of iron-filings, or small pieces of iron, the water will be separated into its constituent parts, the oxygen will combine with the iron, and the hydrogen gas will pass off, and may be collected in proper vessels.

Exper. 4.—The decomposition of water is easily effected by means of galvanism. If the opposite wires of a galvanic battery be made to complete the circuit within a small glass tube filled with water, the water is separated into its elements; the oxygen gas is given out from the positive wire, and hydrogen from the negative wire; and if wires of platina be employed, both gases may be collected either in the same tube or separately. If they are collected in the same tube, and again exploded by a spark, by bringing the wires into contact, the two gases return to the state of water. This experiment shews both the decomposition and composition of water.

Exper. 5.—If hydrogen gas be admitted from a gas-holder, by a very small current, into a large glass vessel filled with common air, and set fire to; by the slow combustion a thin vapour will soon dim the inside of the glass; and as it is condensed on the sides of the vessel, which should be covered with wet cloth on the outside, and kept cool by the application of cold water, it will soon collect into drops and trickle down the sides of the glass. In the course of an hour a perceptible quantity of water may be obtained.

A cubic foot of water, at the temperature of 55°, weighs 998.74 avoirdupois ounces, of $437\frac{1}{2}$ Troy grains each. Water exists in three different states—in the solid state or ice, in the liquid, and in that of vapour or steam. When water is cooled down to the temperature of 32°, it becomes solid. Assuming in this state a crystalline form, the crystals crossing each other at angles of 60° or 120°, it increases in bulk from the new arrangement of its particles, and exerts a prodigious expansive force. The specific gravity of ice is consequently less than that of water. When the temperature rises above 32°, caloric is absorbed, and the ice returns to the liquid state. Water possesses the singular property of reaching its maximum of density at the temperature of about 42°, and not, as it might be expected, as it approaches more nearly to the freezing point. But when the temperature is raised to the boiling point or 212°, the whole is converted into an elastic invisible fluid, which is known by the name of vapour or steam. This remarkable change in the constitution of water, is owing to the absorption of a quantity of caloric, and such a quantity as would have raised the water, if no change had taken place, to the temperature of nearly 1000°. In the state of steam, the water has increased 1800 times in bulk, from which its expansive force must be prodigious, and hence its application as the moving power in the steam-engine.

Sect. II. *Ammonia.*

The combination of hydrogen with azote, affords an important compound. No change takes place when hydrogen and azotic gases are mixed together; and indeed no process is yet known by which a direct combination of the two gases can be obtained; but when they are brought together in the moment of evolution from the bodies with which they were formerly combined, or in their nascent state as it is called, they unite and form ammonia. But for an account of the properties of this substance, we must refer to its proper place among the alkalies.

Chap. VI. Of Carbone.

It was conjectured by Sir Isaac Newton, that the diamond, from its great refractive power, is a combustible substance. Repeated experiments have fully confirmed the conjecture of that sagacious philosopher; and to this combustible matter the name of carbone is assigned in the modern chemical nomenclature. The diamond, then, is supposed to be carbone in its crystallized state, and in the purest form in which it is found to exist. Some experiments indeed seem to lead to the conclusion that it contains a small portion of oxygen; and, according to others, its refractive power is increased by a portion of hydrogen which enters into its composition.

The diamond is the hardest and most indestructible substance in nature; is remarkable for its brilliancy; has the property of absorbing light, for when it is exposed to the sun's rays and carried into a dark place, it is luminous; and it is a non-conductor of electricity, for it becomes sensibly electric by friction.

The combustible property of the diamond has been established by numerous experiments; and the product of that combustion being examined, the quantity of carbonic acid gas, which is a compound of carbone and oxygen, is exactly equal to the proportion of the diamond and the oxygen gas consumed. These experiments were generally made by exposing a portion of diamond in oxygen gas, to the action of a burning-glass. A striking analogy was thus observed between the diamond and charcoal, from the combustion of which a product of the same nature is obtained; but the one is a compound, and the other a simple substance. Charcoal, which is composed of carbone and oxygen, is a black, porous, light substance, and burns in the heat of an ordinary fire. But the diamond is a brilliant, extremely hard body, and requires for its combustion a temperature not less than 5000°.

It was proved by the experiments of Guyton Morveau, that carbonic acid is composed of 17.88 diamond, and of 82.12 oxygen, in 100 parts; and according to the experiments of Lavoisier, 28 parts of charcoal require only 72 parts of oxygen to produce 100 parts of carbonic acid. From these experiments it appears, that carbonic acid is obtained by the combustion both of the diamond and charcoal; but as the latter requires a smaller proportion of oxygen to make up the 100 parts of carbonic acid, it must contain the difference of the quantity of oxygen, between the quantity with which it combines and the quantity necessary to convert the diamond into the same acid. Thus charcoal requires only 72 parts of oxygen, but the diamond requires 82.12; and hence the difference of 10.12 parts must have been previously combined with the charcoal before combustion. According to this statement, the 28 parts of charcoal are composed of 17.88 diamond and 10.12 oxygen. But it ought to be noticed, that the result of other experiments fixes the amount of charcoal at 24 parts only in the 100 parts of carbonic acid.

Sect. I. *Charcoal.*

Charcoal is to be considered, from the experiments already alluded to, as a compound of carbone or diamond, and oxygen; and as this compound possesses no acid properties, it is distinguished by the name of oxide.

Preparation.—Charcoal is prepared in the large way by a kind of smothered combustion, or by exposing it to a high temperature, and at the same time by excluding the air as much as possible. But for the purpose of experiment, small slips of wood may be introduced into a crucible, which is to be filled up with sand, and exposed to the greatest heat of a wind furnace. If the charcoal be required in the state of powder, it may be purified by washing it with diluted muriatic acid, and then with a large portion of pure water.

Properties.—Charcoal thus prepared, in the solid state, is a black brittle substance, without taste or smell, conducts heat slowly, but is a good conductor of electricity, is insoluble in water, but readily absorbs moisture and air. It resists the putrefaction of animal substances, and removes the offensive smell from tainted flesh or putrid water. It is employed as an excellent tooth powder. Charcoal is quite indestructible. Stakes charred on the outside, which seems to have been a common practice with the ancients, have remained in the ground for some thousand years in the most perfect preservation.

Exper. 1.—Let a jar be filled with common air over mercury, and having made a piece of charcoal red hot, plunge it under the surface of the mercury till it is cold, and introduce it under the jar; a diminution of the bulk of the gas is immediately observed, in consequence of the absorption of the air by the charcoal, and the mercury rises in the jar. But if a little water be afterwards introduced, the charcoal absorbs the moisture and gives out the air, and then the mercury is again depressed.

Exper. 2.—If pure charcoal be raised to a red heat, and introduced into a jar filled with oxygen gas, it burns rapidly, and throws out brilliant sparks, but with little flame; the charcoal disappears if the quantity of gas be sufficient, and the oxygen gas is totally changed in its properties; for it is converted into carbonic acid, which is a compound of carbone and oxygen. The bulk of the gas originally employed is not materially changed, but the combination of carbone gives it a greater degree of density.

Sect. II. *Carbonic Oxide Gas.*

Carbone and oxygen unite in different proportions; and to one of these compounds which was particularly examined by Mr Cruickshank of Woolwich, the name of gaseous oxide of carbone, or carbonic oxide gas, has been given. It contains a smaller proportion of oxygen than what exists in carbonic acid.

Preparation.—If carbonic acid gas be passed through red hot charcoal in an iron or porcelain tube, the carbonic acid is decomposed, part of the oxygen combines with the charcoal in the tube, and carbonic oxide gas is formed. It may be obtained also by subjecting to a strong heat one part of pure charcoal, with three parts of chalk, or any other carbonate; and may be purified from any portion of carbonic acid with which it is mixed, by washing it with lime-water.

Properties.—Carbonic oxide gas possesses the physical properties of common air; 100 cubic inches weigh 30 grains; water absorbs about one-tenth of its bulk; it is unfit for respiration; but it is combustible, and burns on the application of an inflamed body, with a lambent blue flame. It is neither inflamed nor diminished by the electric spark; but if passed through a red hot tube full of air, slight detonations take place, and the residue of this combustion is carbonic acid and azote; so that the oxygen of the atmosphere has united with the carbonic oxide and has formed carbonic acid, while the azotic gas is set free.

Exper. 1.—If two measures of carbonic oxide gas be mixed with one measure of oxygen gas, and the electrical spark be passed through the mixture, the product of the combustion is two measures of pure carbonic acid.

It has been supposed by some, that it may be owing to this gas disengaged from burning charcoal, that sudden death is often induced in close apartments.

Sect. III. *Carburetted Hydrogen Gas.*

Carbone enters into combination with hydrogen, and forms with it two distinct compounds, one of which is called carburetted hydrogen gas, and the other super-carburetted hydrogen gas or olefiant gas.

Carburetted hydrogen gas.—If the saline substance called acetate of potash, which is a compound of acetic acid and potash, be exposed to a red heat, the vegetable acid, consisting of carbone, hydrogen, and oxygen is decomposed, and the carbone and part of the hydrogen unite and form carburetted hydrogen gas, which may be collected in proper vessels over water. The same gas may be obtained by the distillation of common pit-coal; and it is by this process that the inflammable air which supplies the gas lights is prepared. To render it pure, it should be washed with lime-water, to separate the carbonic acid with which it is mixed. This precaution is also necessary in the economical application of the gas from coal.

The decomposition of vegetable matters affords a copious evolution of the same gas; and accordingly it is given out in great abundance from stagnant waters during the hot season of the year.

Properties.—Carburetted hydrogen gas has no taste, but the smell is peculiar and disagreeable; 100 cubic inches weigh about 17 grains; and water absorbs about one-thirtieth part of its bulk. It burns with a bright yellowish flame.

Exper. 1.—If one measure of this gas and two measures of oxygen gas, be inflamed over mercury by the electric spark, the whole is converted into carbonic acid and water. One measure of carbonic acid gas is obtained.

In this experiment part of the oxygen combines with the hydrogen of the carburetted hydrogen gas, and forms water; and another part of the oxygen unites with the carbone and forms carbonic acid.

Super-carburetted hydrogen gas.—If a mixture of four parts of oil of vitriol or sulphuric acid, with one part of strong spirits of wine be heated in a retort, a gas is obtained, which has received this name from the larger proportion of carbone which enters into its composition. It may be collected over water; and to render it pure it is found necessary to wash it.

Properties.—This gas has a peculiar disagreeable odour; it is 13 times heavier than hydrogen gas; 100 cubic inches weigh nearly 30 grains, water absorbs about one-eighth of its bulk; it burns with great splendour, and with a beautiful white flame; and this gas, as well as the former, is unfit for respiration.

When this gas is mixed with oxymuriatic gas or chlorine, the bulk is diminished, and if mixed in nearly equal proportions the whole is condensed into a peculiar fluid, which has somewhat the appearance of an oil; and hence the name of olefiant gas by which the Dutch chemists who first described it in 1794, distinguished it.

Carburetted hydrogen gas was formerly denominated light inflammable air and heavy inflammable air, as it was found to differ in its specific gravity according to the nature of the substance from which it was obtained, and the process employed. But the experiments of later chemists have shewn that this difference is owing to mixtures of olefiant gas, carbonic oxide, and hydrogen gases with the carburetted hydrogen gas.

Chap. VII. Of Phosphorus.

This singular substance was discovered by Brandt of Hamburgh, about the year 1669, while he was engaged in searching for the philosophers stone. Kunkel and other chemists having seen the new product, and having obtained, it is said, some hints of the nature of the process by which it was obtained succeeded in the discovery. Mr Boyle who is also considered one of the discoverers of phosphorus, communicated the secret to the Royal Society in 1680, and instructed Godfrey Hankwitz, a London apothecary, in the mode of preparing it, who supplied all Europe for several years with phosphorus; and hence it was known under the name of *English phosphorus*. An important discovery was made in 1774, by Gahn and Scheele, that phosphorus is contained in the bones of animals; and this discovery greatly facilitated the processes for its preparation.

Preparation.—Having reduced a quantity of burnt bones to powder, put 100 parts into a porcelain or stoneware basin, dilute it with four times its weight of water, and add 40 parts of sulphuric acid in small portions, stirring the mixture; after every addition a violent effervescence takes place, and a great deal of air is given out. The mixture should remain for a day or two, and should be occasionally stirred to expose every part of the powder.

The nature of this process may be understood by considering that bones are chiefly composed of lime united to phosphoric and carbonic acids; but the sulphuric acid having a stronger affinity for the lime, than either the phosphoric or carbonic acids, separates these two acids, one of which remains in the liquid, and the other, the carbonic acid, passes off in the state of gas, while the sulphuric acid and the lime form an insoluble compound, and fall to the bottom.

Filter the liquid through cloth, and having repeatedly washed the sulphate of lime that remains upon it, add to the liquid which has passed through the cloth a solution of nitrate of lead in water, as long as any precipitation is formed. Pour the whole again upon a filter, and let the white powder which remains be well washed and dried. Mix the dried powder with one-sixth of its weight of charcoal dust, and put the mixture into an earthen ware retort, which should be previously coated to resist the strong heat to which it must be exposed. To the beak of the retort it may be necessary to apply a long tube, well secured at the joinings, and the extremity of which is to be kept under water. After the heat is applied, a great deal of gas is given off, which inflames spontaneously as it reaches the surface of the water; a substance at last somewhat similar to melted wax drops out, and congeals under the water. This substance is phosphorus. It is farther purified by straining it through chamois leather, while it is melted under water, and it is formed into sticks by putting it into a glass funnel with a long tube, immersing it in boiling water, and when the phosphorus is melted and flows into the tube, it is suddenly plunged in cold water to make it congeal. It should be preserved in close vessels filled with pure water, and excluded from the light.

Properties.—Phosphorus is nearly of the consistence of wax, semi-transparent, has an acrid disagreeable taste, and a peculiar offensive smell, somewhat resembling garlic. The specific gravity is 1.77; when the air is excluded it becomes liquid at 99°, and boils at 554°. At the temperature of 44° it gives out a white smoke, and is luminous in the dark; but when the temperature is raised to 148°, it takes fire, burns with a bright flame, and throws off a great deal of dense white vapour.

Exper. 1.—Write a word on a board with a stick of phosphorus, and carry it into a dark room; it will appear luminous, particularly if the temperature of the room be not very low.

Exper. 2—Take a thin slice of phosphorus, and having dried it well with a cloth, wrap it up in a bit of paper, and rub it smartly with a bit of dry soft wood; the temperature will be so much raised by the friction as to inflame it.

Exper. 3.—Wrap up a bit of phosphorus well dried in a little cotton, and place it under the receiver of an air-pump. When the air is exhausted to a certain degree, the phosphorus will take fire.

In all experiments with phosphorus, the precaution should be carefully observed of never touching it with the fingers.

Sect. I. *Oxide of Phosphorus.*

Exposed to the light, or kept in water not entirely freed from air, phosphorus soon loses its transparency, becomes white, and is afterwards covered with a dark brown crust. This is the lowest degree in which phosphorus combines with oxygen, and the compound is called an oxide of phosphorus. This change shews that it is necessary to keep it excluded from the air and light, and for this purpose the water in which it is preserved should be boiled, and the vessels containing it should be kept in a dark place. It is easy to purify phosphorus from this oxide, by melting it in water; at the temperature of about 100°, the oxide separates and swims on the surface.

Phosphoric matches.—Put a small bit of phosphorus into the bottom of a long narrow glass tube, and expose it to the heat of boiling water; the phosphorus becomes luminous and rises in the form of a white vapour, which attaches itself to the sides of the tube. This also is an oxide of phosphorus, which readily takes fire with a moderate heat; and for this purpose it is employed to communicate a light to sulphur matches, merely by taking out a little of it and exposing it to the air. To render it more combustible, a small portion of oil or sulphur is added to the phosphorus.

Acids.—When phosphorus is burnt in common air confined in a vessel, a rapid combustion takes place, a great quantity of white fumes is produced, and these fumes being mixed with water exhibit acid properties. This is phosphorous acid, in which the oxygen is in smaller proportion than the phosphoric acid.

But if phosphorus, in a state of inflammation, be introduced into a jar of oxygen gas, the combustion is more splendid, the evolution of the white fumes is more copious, and a concrete substance is formed, which adheres to the sides of the jar. The product of this combustion is phosphoric acid, to be afterwards treated of.

When phosphorus is kept for some time in azotic gas, a small portion is dissolved, and the azotic gas being saturated with the phosphorus is increased about one-fortieth part of its bulk, and the compound is called phosphuretted azotic gas, which becomes luminous when it is mixed with oxygen gas; but the combustion is more brilliant when the phosphuretted azotic gas is gradually let up into a jar of oxygen gas.

SECT. II. *Phosphuretted Hydrogen Gas.*

Phosphorus enters into combination with hydrogen when it is kept for some hours in a jar exposed to its action. A small portion of phosphorus is dissolved, and when the phosphorised gas, as it is called, is introduced into a jar of oxygen gas, a brilliant bluish flame fills the whole vessel. The same effect is not produced in atmospheric air. This gas has a slight smell of garlic.

Phosphuretted hydrogen gas was discovered by M. Gengembre in 1783, by boiling phosphorus in a solution of pure potash, in a small retort, and collecting the gas in vessels over water. It may be prepared also by melting phosphorus by means of a burning glass, in a jar of hydrogen gas standing over mercury. But this gas may be obtained more easily, by taking about an ounce of slaked quicklime, and 30 grains of phosphorus, and having reduced the whole to a soft paste with a little water, introducing it into a small glass or stone-ware retort, the body of which should be filled with the materials. The beak of the retort being immersed in water, and heat applied, the gas begins to pass over, and when the bubbles come to the surface they explode with flame and smoke. By another method of preparing this gas, phosphuret of lime, which is a compound of phosphorus and lime, is put in small pieces into a retort filled with water, to which a small portion of muriatic acid has been added, and as it is given off it is collected over water in the usual way.

In all these processes a decomposition of the water takes place; part of the phosphorus combines with the oxygen, and forms phosphoric acid, which unites with the potash or lime; and another part of the phosphorus uniting with the hydrogen of the water, passes off in the state of phosphuretted hydrogen gas.

Properties.—In its physical properties this gas resembles common air; it is colourless, smells like putrid fish, has a very bitter taste, and at the mean temperature and pressure of the atmosphere 100 cubic inches weigh $27\frac{1}{2}$ grains. When kept over pure water it remains unchanged.

But the most remarkable property of this gas is its spontaneous inflammation when it comes in contact with the air of the atmosphere. When the gas passes off slowly, the bubbles are of a larger size, and when they reach the surface they exhibit an elegant appearance, forming after explosion a beautiful coronet of white vapour, which rises with an undulatory motion in still air. When it is brought in contact with oxygen gas the combustion is still more rapid and more brilliant. If a quantity of the gas, to the extent of two or three ounces, be collected in a small jar, and if it be removed from the shelf of the pneumatic apparatus on a saucer, and turned with its mouth upwards, the moment the saucer is removed the whole bursts into a copious flame.

In the combustion of this gas, phoshoric acid and water are formed. The phosphorus held in solution by the hydrogen gas combines with the oxygen, and forms phosphoric acid, while the hydrogen unites with another portion of the oxygen gas of the atmosphere, and forms water.

SECT. II. *Phosphuret of Carbone.*

Phosphorus enters into combination with carbone, and forms with it a compound which is denominated phosphuret of carbone. This substance is said to be produced during the distillation of phosphorus, and it remains behind on the leather through which it is strained to purify it. It is of a reddish colour, and does not melt like pure phosphorus. When it is distilled with a gentle heat, a small portion of phosphorus is separated, and what is supposed to be the phosphuret of carbone, which requires a very powerful heat for its decomposition, remains behind, and is in the form of a flocculent powder, of a lively orange red colour. Subjected to red heat, the phosphorus is driven off, and the charcoal remains; and when it is placed on a heated metallic plate, it burns rapidly in the open air. But some chemists suppose that the charcoal is merely mixed with the phosphorus, or in triple combination with oxygen and hydrogen.

CHAP. VIII. OF SULPHUR.

Sulphur is a simple combustible substance, which is universally diffused in nature, but it is most commonly in combination with mineral, vegetable, or animal matters. It exists in some mineral waters, and is met with in great abundance in volcanic countries, where it becomes a valuable commercial commodity.

Properties.—Sulphur, as it is purified by art, is a hard brittle substance, of a yellow colour, always opaque, and becomes electric by friction. The specific gravity is double that of water; it has no smell, and little taste. It is volatilized by rubbing, and diffuses a peculiar and slightly fetid odour. It is insoluble in water.

If a roll of sulphur be held for a little in the hand, it begins to crackle, and at last breaks to pieces. When sulphur is exposed to heat in close vessels it rises in the form of a fine powder, which is well known by the name of flowers of sulphur. When heated in contact with the air, and raised to the temperature of 300°, it becomes gradually thick and viscid, and if it be then poured into cold water it retains its softness, and is employed for taking impressions of seals or medals. But when the temperature is kept at that of boiling water, it retains its transparency, changes to a brownish red colour, and if it be permitted to cool slowly, crystallizes in the form of prismatic needles. But better crystals are obtained by pouring out part of the liquid sulphur as soon as the surface becomes solid.

When sulphur is burnt in the open air it gives out a pale blue flame, with a great quantity of white suffocating fumes; and if it be heated in dry oxygen gas, it burns with a violet coloured flame, and sulphurous acid gas is the product. But when a larger portion of oxygen combines with the sulphur, sulphuric acid is formed.

SECT. I. *Sulphuretted Hydrogen Gas.*

Sulphur enters into combination with hydrogen, and forms with it a gaseous compound. This gas may be prepared by subliming sulphur in dry hydrogen gas in a retort, or by pouring diluted sulphuric acid on a mixture of three parts of iron filings, and two parts of sulphur, that have been fused together in a crucible; and as it is rapidly absorbed by water it should be collected in vessels over mercury.

Properties.—This gas, formerly called *hepatic* gas, is colourless, and possesses the physical properties of common air; the smell is extremely fœtid; it is unfit for respiration or for supporting combustion; 100 cubic inches weigh about 36 grains; and it burns with a reddish blue flame, and deposits sulphur. Water absorbs more than its own bulk of this gas, which communicates to it a fœtid odour, and a nauseous, somewhat sweetish, taste. This water reddens vegetable blues, and has other properties of an acid. When it is exposed to the air the hydrogen gas escapes, and sulphur is deposited. It is from this deposition that sulphur found near mineral springs is derived. The constituent parts of sulphuretted hydrogen are about 71 parts of sulphur and 29 of hydrogen.

Sect. II. *Sulphuret of Carbone.*

The compound of sulphur and carbone is a substance which possesses peculiar properties; and in particular is remarkable for its volatility, and consequently for its power of producing cold. It was originally examined by the French chemists, and more lately by others.

Preparation.—A porcelain tube, passed through a furnace in an inclined position, is filled with charcoal; to the lower extremity of the tube a glass tube is luted, and its other end terminates in a vessel of water; to the other extremity of the porcelain tube is luted another glass tube, sufficiently wide to contain small bits of sulphur, which are to be pushed successively into the porcelain tube, with an irod rod passing through the cork which closes the end of the tube. The porcelain tube with the charcoal is made red hot, and pieces of sulphur are pushed slowly forward into the tube; the sublimed sulphur acts on the charcoal; a liquid of a yellow appearance passes through the tube; and the heat being continued, this liquid evaporates, and is condensed in the water of the vessel in which the tube terminates, and collects at the bottom. In the management of this process the sulphur should not be exposed suddenly to a strong heat; but the pieces of sulphur should be gradually introduced, that the vapour may not pass too rapidly through the tube.

Properties.—When first prepared the colour is yellowish; but after distillation, at a temperature not much exceeding 100°, it becomes quite transparent and colourless; the taste is acrid, and the smell pungent and disagreeable. The sulphuret of carbone is heavier than water, but it is nearly insoluble in that liquid; evaporates readily at the ordinary temperature of the atmosphere, and when the heat is raised to a little above 100° it boils; it burns with great facility and with a bluish flame; but when it is mixed with oxygen gas, and brought in contact with a burning body, it explodes with great violence, and, if the quantity of oxygen gas be sufficient, the whole is converted into carbonic acid. The constituent parts are 85 of sulphur and 15 of carbone.

Exper. 1.—The most remarkable property of the sulphuret of carbone, is its extreme volatility. If a quantity of this liquid, in a vessel of water, be placed under the receiver of an air-pump and the air exhausted, it rises through the water in the gaseous form; and when the pressure of the air is restored, it returns to the liquid state.

Exper. 2.—Put a little of the liquid itself, along with a thermometer, under the receiver of an air-pump, and let the receiver be quickly exhausted, the thermometer will sink in a few minutes 70° or 80° below 0°.

Exper. 3.—If the bulb of a thermometer be covered with fine lint, and after being immersed in the liquid, exposed to a current of air, the mercury will sink from 60° to 0°.

Sect. III. *Sulphuret of Phosphorus.*

Sulphur and phosphorus unite together in various proportions; and in whatever proportions they are combined, the compound becomes liquid at a much lower temperature than either of the ingredients, and in equal proportions it remains liquid at the lowest temperature.

Preparation.—The phosphorus and sulphur, in whatever proportions they are employed, are introduced into a flask or retort which is filled with pure water, heat is slowly and very cautiously applied, and when the phosphorus melts the combination takes place; but if the temperature be raised, the danger of explosion is considerable, from the decomposition of the water, the hydrogen of which, combining with sulphur and phosphorus, forms sulphuretted and phosphuretted hydrogen gases.

Properties.—The sulphuret of phosphorus is of a yellowish white colour, and somewhat crystallized in its appearance; it is not only liquid at a lower temperature than either of the constituent parts, but it is also more combustible; and this combustibility is increased by allowing the compound to burn for a little, and then, by excluding the air, to extinguish it. In this state it takes fire spontaneously in the open air, or by taking a little of it from a close vessel on the end of a match. Eight parts of phosphorus and one of sulphur remain liquid at 95°; one part of phosphorus and three of sulphur at 99°; but equal parts remain liquid when the temperature is reduced to 41°.

Chap. IX. Of Acids.

The acids constitute a very important class of bodies, not only in the changes which are going on in nature, and in the processes of art, but also as chemical agents. It is necessary, therefore, to be early acquainted with their nature and properties.

The substances which have been treated of in the five preceding chapters, enter into combination with oxygen in different proportions, with the exception of hydrogen, which combines only in one proportion, and the compound obtained is water. The first portion of oxygen which unites with the other substances forms compounds, which are distinguished by the name of oxides, because they are destitute of acid properties; but when a larger proportion of oxygen enters into the combination, new properties are acquired, which place them in the class of acids.

Characters.—This class of bodies is distinguished by a peculiar taste, which is familiar under the name of acid or sour; they redden vegetable blues; they combine readily with water, and enter into chemical union with alkalies, earths, and metallic oxides, and form compounds called *salts*.

Tests of acids.—Vegetable blue colours which are converted into red by the action of acids, are employed as tests to discover their presence. The infusion of red cabbage is most commonly applied to this purpose. It is prepared by dividing the thinner part of the leaves into shreds, and having poured on boiling water, let it stand for a few hours; or it may be prepared more speedily by boiling the cabbage for a short time. The infusion of the purple violet, or of mallow flowers, is prepared in the same way. Blue infusions of the same kind may be obtained from other flowers, and one of the most beautiful may be extracted from the dark purple columbine. Unsized paper stained with violets, mallows, or the raddish-root, answers the same purpose. The infusion or tincture of litmus, is the most proper test for carbonic acid. A single drop of the stronger acids will change a large quantity of the infusion to a fine red colour.

Names.—The *base* of an acid is the substance which combines with the oxygen, and acquires new properties. Sulphur is the base of sulphuric acid, and phosphorus is the base of phosphoric acid. But as oxygen combines in different proportions with these bases, the acid products have very different characters, and are therefore distinguished by different names. When the oxygen exists in the acid in the smaller proportion, the termination of the name is in the syllable *ous*, and when in the larger proportion it terminates in *ic*; thus *phosphorous* acid and *sulphurous* acid indicate the smaller proportion of oxygen; and *phosphoric* acid and *sulphuric* acid are expressive of the larger proportion of oxygen in the compound. While the acids form compounds with the alkalies, earths, or metallic oxides, the termination of the name of the salt is characteristic of the acid which enters into its composition. *Sulphite* or *phosphite* of soda denotes the compound to be derived from sulphurous or phosphorous acid; and *sulphate* or *phosphate* of soda, shews that sulphuric or phosphoric acid forms part of the combination. When the acids have been sometimes divided into mineral, vegetable, and animal, according to the sources from which they are derived, an arrangement has also sometimes been adopted of dividing them into such as have one, and such as have two bases. Most of the vegetable acids, as will appear afterwards, have a double base of carbone and hydrogen; but without pursuing any formal arrangement, which is generally connected with some theoretical views, the principal characters of the more important acids, with the method of procuring them, shall be detailed in the present chapter.

Sect. I. *Sulphuric Acid.*

Sulphuric acid, which is a compound of sulphur and oxygen, when the oxygen unites with the sulphur in the larger portion, seems to have been first noticed about the end of the 15th century, but was not particularly described till after the middle of the 16th century. It was formerly denominated vitriolic acid, because it was obtained from the metallic compounds called vitriols, and particularly, as at the present day, in some places from green vitriol or sulphate of iron; and, from its sluggish appearance when concentrated, was long known by the name of *oil of vitriol*.

Preparation.—If flowers of sulphur in a state of inflammation be introduced into a jar of oxygen gas, a splendid combustion, with the copious evolution of white fumes, takes place; and these fumes being condensed by a little water in the bottom of the jar, the water is found to possess acid properties.

The manufacture of sulphuric acid in the large way, is conducted by burning, in close leaden chambers, seven parts of sulphur with one part of nitre. In this process the sulphur, combining with a portion of oxygen, is converted into sulphurous acid gas; nitrous gas appears from the decomposition of the nitre, and combining with oxygen, becomes nitrous acid gas; the two gases unite, form a white crystalline solid, and being absorbed by the water at the bottom of the chamber, undergo another change. The sulphurous acid robs the nitrous acid of its oxygen, and is converted into sulphuric acid; while the nitrous gas, resuming its elastic form, separates from the water. This process is continued, till the water at the bottom of the chamber has become strongly acid. It is afterwards concentrated by evaporation in leaden vessels, and to render it still stronger it is distilled in glass vessels. This distillation is also necessary to separate some combinations of lead and potash, which are formed during the process.

Properties.—When the fuming acid, as it is prepared in some places of Germany, is distilled in glass vessels with a moderate heat, the fuming portion may be collected separately in a receiver cooled with ice; and it appears in the solid form, resembling silky filaments, with some degree of tenacity. It fumes strongly in the air, and is gradually dissipated in vapour, but continues solid till the temperature reach 60°.

In its ordinary state of purification, sulphuric acid is a transparent, colourless liquid, of an oily consistence, without smell, but having a strong acid taste; reddens vegetable blues, and acts powerfully on animal and vegetable matters. The specific gravity, when as much as possible concentrated, is double that of water; but it rarely exceeds 1.84. The boiling point of sulphuric acid varies with the proportion of water; when the specific gravity is 1.850, it requires a temperature of 620°; and when it is reduced to the specific gravity of 1.0, it boils at 218°. Sulphuric acid of the specific gravity of 1.780 freezes at 45°, and continues solid at the temperature of 48°. It crystallizes in flat six-sided prisms, terminating in a six-sided pyramid; but it has the singular property of freezing most readily at a certain specific gravity, and if it be either more or less concentrated, it requires a greater diminution of temperature. Sulphuric acid has a strong attraction for water; and as a condensation takes place between the two liquids, heat is evolved during the combination; when the solid acid is dropt into water, the combination and condensation are so rapid as to produce an effect similar to that of red hot iron, by the sudden formation and extrication of the vapour of the water. If strong sulphuric acid be exposed to the air, it will attract in a few days more than six times its own weight of water. If one part of ice, and four parts of concentrated sulphuric acid, be mixed together, the ice instantaneously melts, and the temperature rises to 212°; but if the same proportions of acid and water be suddenly mixed together, the temperature of the mixture approaches to 300°.

The composition of sulphuric acid is stated, according to the analysis of Lavoisier, to be 71 of sulphur and 29 of oxygen in the 100 parts; but according to the analysis of Mr Chenevix, the proportions are 61.5 of sulphur, and 38.5 of oxygen.

If hydrogen gas and sulphuric acid be brought into contact, no action takes place in the cold; but being passed through a red hot porcelain tube, the acid is decomposed, water formed, and sulphur precipitated; and if the hydrogen gas be in large proportion, the sulphur is dissolved, and is disengaged in the form of sulphuretted hydrogen gas. Charcoal, at the boiling temperature, deprives sulphuric acid of a portion of its oxygen, and converts it into sulphurous acid, and carbonic acid is also formed; phosphorus, with the assistance of heat, also decomposes sulphuric acid—and the products are phosphoric acid and sulphurous acid; and sulphur being boiled with sulphuric acid, converts the whole into sulphurous acid.

The compounds of sulphuric acid with alkalies, earths, and metallic oxides, are known in modern chemical language by the name of *sulphates*.

Sulphuric acid is very extensively employed in many arts and manufactures; it is also used in medicine and pharmacy; and hence the preparation of this acid has been long an object of great importance.

Sect. II. *Sulphurous Acid.*

Sulphurous acid contains oxygen combined in its smaller proportion with sulphur; it was formerly called spirit of sulphur, and volatile sulphurous acid, from its peculiar properties.

Preparation.—The fumes of sulphur burnt in the open air consist of sulphurous acid; but it is more conveniently prepared by heating one part of mercury, and two parts of concentrated sulphuric acid, in a glass retort; a gas is disengaged, which should be collected in jars over mercury. This is sulphurous acid gas. In this process, part of the oxygen of the sulphuric acid combines with the mercury, and the sulphurous acid is separated.

Properties.—In the state of gas it has the physical properties of common air, has a pungent smell, is unfit for respiration, or for the support of combustion, reddens vegetable blues, and then destroys them; and 100 cubic inches weigh nearly 63 grains.

When strongly heated in a porcelain tube, sulphur is deposited. When the temperature is diminished by a freezing mixture to 31° below *zero*, the gas becomes liquid. If sulphurous acid gas and oxygen gas be passed through a red hot tube, they are converted into sulphuric acid; and when hydrogen gas and sulphurous acid gas are treated in the same way, the oxygen combines with the hydrogen, and forms water, and sulphur is deposited. If charcoal and sulphurous acid gas be exposed to a red heat, carbonic acid is formed, and the sulphur is set free. Phosphuretted hydrogen gas is decomposed by sulphurous acid gas; the hydrogen of the one combines with the oxygen of the other, and forms water, while the sulphur and phosphorus are deposited in the solid state. When sulphuretted hydrogen gas comes in contact with sulphurous acid gas, an instantaneous condensation is effected, water is formed, and solid sulphur is deposited, with the evolution of a great deal of heat. Water has a strong attraction for this gas. A bit of ice brought in contact with it is immediately melted. Water at the temperature of 40° is said by some to absorb the third of its weight of the gas; but, according to others, the proportion is not more than one-twelfth at the temperature of 60°. This water freezes at a few degrees below 32, without parting with any of its acid. Liquid sulphurous acid has the taste, smell, and other properties of the gas, and particularly that of destroying vegetable colours. Exposed to the atmosphere, it absorbs oxygen, and is converted into sulphuric acid.

Sulphuric acid separates sulphurous acid in the gaseous form from water and its other combinations. Concentrated sulphuric acid absorbs sulphurous acid gas, becomes of a brown colour,, and acquires a pungent odour; the fumes first given off by the action of heat crystallize in needle-shaped prisms. This substance was formerly called glacial sulphuric acid.

Sulphurous acid is much employed in the arts, and particularly in the bleaching of silk and woollen stuffs; it removes the stains arising from vegetable juices, and spots of iron from linen. By the analysis of some chemists, the proportion of the constituents in 100 parts are 85 of sulphur, and 15 of oxygen; but according to others, the proportion of sulphur is 68, and of oxygen 32°: the saline compounds with sulphurous acid are called *sulphites*.

Sect. III. *Nitric Acid.*

This acid, the constituent parts of which are now ascertained to be azote and oxygen, was known to the alchemists before the middle of the 13th century; and the process for preparing it is described by Basil Valentine, who lived in the 15th century. He distinguished it by the name of *water of nitre*; and before it received its present appellation, it was successively denominated *spirit of nitre*, and *aqua fortis*. Nitric acid exists in great abundance in nature; its constituent parts are evolved during the putrefactive process of animal and vegetable matters, but it is always in combination with some base.

Preparation.—If three parts of nitre or saltpetre, with one of sulphuric acid, be mixed together in a glass retort, to which a glass receiver is secured, by luting or grinding, and a strong heat applied to the retort, a gas is given out during the process, which, being condensed in the receiver by the application of wet cloths, is nitric acid. The nature of this process will be easily understood by considering that nitre is composed of nitric acid and potash, and that sulphuric acid, having a stronger affinity for the potash, combines with it, and the nitric acid of the nitre being set free is expelled by the heat, and condensed into the liquid form when it enters the cooled receiver. To purify the acid thus obtained, it is distilled, with the addition of some substances, as nitrate of silver, to separate the muriatic acid, and nitrate of barytes to separate the sulphuric acid, with which it is usually contaminated. The acid is still of a reddish colour, from the fumes of nitrous gas, but these fumes may be separated by the application of a gentle heat.

Properties.—Thus prepared and purified, nitric acid is transparent and colourless, has a strong acid taste, a pungent odour, is very corrosive, and communicates to the skin a yellow stain. The specific gravity of the strongest acid is stated at 1.62, but it rarely exceeds 1.554. It has a very strong affinity for water, and is never entirely deprived of that liquid; it readily attracts moisture from the air, and when water is added heat is evolved in consequence of the condensation of the mixture.

When nitric acid is exposed to the light it is partially decomposed, nitrous gas is formed, which, mixing with the acid, communicates an orange yellow colour. The boiling point of nitric acid varies according to the proportion of water which it contains. With a specific gravity of 1.42, it requires a temperature of 248°, but when the specific gravity is either greater or less it boils at a lower temperature. When it is passed through a red hot tube it is converted into its constituent parts, oxygen and azotic gases; and when it is cooled down to 66° below *zero*, it crystallizes in a few minutes, assumes a deep red colour, and by agitation congeals into a thick mass like butter.

Nitric acid, when passed through a red hot tube with hydrogen gas, is decomposed, the hydrogen and oxygen form water, and the azotic gas is set free. Nitric acid and charcoal, exposed to a high temperature, afford carbonic acid and azotic gas; the carbone unites with the oxygen, and azotic gas is expelled. A similar decomposition is effected by phosphorus and sulphur; at a high temperature each of these bodies unites with the oxygen of the acid, and forms phosphoric or sulphuric acids, while the azotic gas, the other constituent of nitric acid, is set free.

The mixture of nitric and sulphuric acids produces heat; for the sulphuric acid attracts the water from the nitric acid, which latter becomes more concentrated, but nitric acid separates sulphurous acid from water and its other combinations, gives out its oxygen, and converts it into sulphuric acid, and passes itself into the state of nitrous gas.

The constituent parts of pure nitric acid are 74 parts of oxygen and 26 parts of azote in 100 parts; the saline compounds of nitric acid are denominated *nitrates*; and it is one of the most important of the acids, whether it be considered as a powerful agent in the hands of the chemist, or as it is employed in the arts, and in medicine.

Exper. 1.—If atmospheric air be gradually admitted into a jar of pure nitrous gas, which is transparent and colourless, reddish fumes make their appearance after every addition of the air, and a condensation takes place in consequence of the aeriform substances being converted into the liquid state, which, combining with the water over which the experiment is performed, the latter rises in the inside of the jar. The liquid thus formed is nitric acid, and the gas remaining is the azotic gas of the atmosphere.

Exper. 2.—If oxygen gas be substituted for atmospheric air, the condensation will be complete; the whole will be converted into nitric acid, and the water will rise to the top of the jar.

Exper. 3.—If the electric spark be passed through common air in a glass tube, the air is diminished in bulk, and nitric acid is formed; and if oxygen and azotic gases be mixed in certain proportions, the whole is converted into nitric acid.

Exper. 4.—Take a glass tube, of about one-sixth of an inch in diameter, close it at one end with a cork, through which a metallic conductor with a ball at each extremity passes, and having filled the tube with mercury, immerse the open end into the mercurial trough, and introduce a mixture of 13 parts of azotic gas, and 87 parts of oxygen gas, occupying 3 inches of the tube, and a solution of potash filling half an inch more. Let electrical explosions be directed through the tube till the air ceases be diminished in bulk. If the ingredients employed be in proper proportion, the potash will be converted into nitre.

These experiments, which were made by Mr Cavendish, afford the most satisfactory evidence of the constitution of nitric acid.

Sect. IV. *Nitrous Acid.*

Nitrous acid, in common language, is a mixture of nitric acid and nitrous gas; but, according to the present chemical nomenclature, it ought to bear the same relation to nitric acid that sulphurous acid bears to sulphuric, that is, it should be a compound of azote and oxygen, having acid properties; but with a smaller proportion of oxygen than what exists in nitric acid. Such an acid can be obtained in a separate state.

Preparation.—If a quantity of dry nitrate of lead be distilled in a glass retort, an orange-coloured liquid is obtained; this liquid is considered to be nitrous acid nearly in a state of purity.

Properties.—The taste of this liquid is strongly acid; it is extremely volatile, and rises in thick fumes. It boils at the low temperature of 82°, and the specific gravity is 1.45. In the state of vapour, nitrous acid remains unchanged by the action of heat; but when nitrous acid is mixed with water, an effervescence takes place, with the evolution of nitrous gas, from which it appears that some change in its constitution is effected, and that it is converted into what is commonly known by the name of nitrous acid.

The saline compounds of nitrous acid are denominated *nitrites*; but these salts are rarely produced by direct combination. If, for example, nitre be exposed to strong heat, a great deal of oxygen gas is given out, which must proceed from the decomposition of the acid; a neutral salt still remains behind, having different properties from those of common nitre. This salt is considered to be a compound of nitrous acid and potash, or nitrite of potash.

As nitric acid combines in different proportions with nitrous gas, it affords many varieties of the nitrous acid, or *aquafortis* of commerce and the arts; and, according to the quantity of nitrous gas absorbed, the acid exhibits very different colours, as yellow, orange, olive, and green. These colours also vary with the proportion of water combined with the acid.

Sect. V. *Muriatic Acid.*

Till the late discoveries of Sir Humphry Davy the constituent parts of muriatic acid were unknown. According to his views it is a compound of hydrogen and chlorine, in which the latter acts the part of an acidifying substance. Of the nature of this substance some account will be given in the next section; in the meantime the properties of muriatic acid may be examined without reference to its composition. The name is derived from the Latin word *muria*, which signifies sea-salt, or common salt, from which the acid is usually obtained, and it has been sometimes distinguished by the names of marine acid, acid or spirit of salt.

Preparation.—Muriatic acid may be obtained by introducing equal parts of common salt and sulphuric acid into a retort; and if the retort communicate with a receiver, in the bottom of which there is a quantity of water to condense the vapour as it passes over, liquid muriatic acid is obtained. But to collect the acid in the state of gas it must be received in jars, inverted over mercury. When it first passes over it is in the form of white fumes, but becomes at last transparent.

Properties.—Muriatic acid gas possesses the physical properties of atmospheric air; the smell is pungent, and disagreeable, and the taste strongly acid; it reddens dry litmus paper, and other vegetable blues; smokes when it is diffused in the atmosphere, by mixing with the aqueous vapour; and 100 cubic inches, at the temperature of 60°, and the pressure of 30 inches, weigh nearly 40 grains. It is rapidly absorbed by water, which, at the temperature of 40°, combines with 480 times its bulk of the gas. When water is saturated with the gas, it is then called liquid muriatic acid. With this quantity of gas the specific gravity of the solution is 1.21. The gas is unfit for respiration or the support of combustion.

Liquid muriatic acid, in its ordinary state, is of a pale yellow colour; but when it is purified by distillation it becomes transparent and colourless. Light has no action on muriatic acid, either in the state of gas or liquid, nor is it affected by oxygen, hydrogen, charcoal, phosphorus, or sulphur. Sulphuric acid separates muriatic acid from its compounds, and even from its combination with water, but muriatic acid expells sulphurous acid from that liquid. Muriatic acid and nitric acid, when mixed together, effervesce, give out heat, and produce a change of colour to an orange red. The compound, called nitro-muriatic acid, was formerly known by the name of *aqua regia*, from its property of dissolving gold, the *king of the metals*, in the language of the alchemists.

The saline compounds which are formed with muriatic acid are distinguished by the name of *muriates*.

Exper. 1.—Fill a jar over mercury with muriatic acid gas, and introduce a little water into the jar, the whole of the gas will be instantaneously absorbed, and the mercury will rise to the top of the jar, thus shewing the strong attraction between the gas and the water.

Exper. 2.—Let a jar be filled with muriatic gas over mercury, and let it be removed into a vessel of water coloured with vegetable blue, as soon as the water comes in contact with the gas it fills the jar, and becomes of a fine red colour. In this experiment the acid properties of the gas, and its rapid absorption by water, are illustrated at the same time.

Sect. VI. *Oxymuriatic Acid, or Chlorine.*

The discovery of oxymuriatic acid, in 1774, is recorded among the labours of the illustrious Scheele; he called it dephlogisticated muriatic acid, because he supposed that it is muriatic acid deprived of its phlogiston. About ten years afterwards it was particularly examined by Berthollet, and, according to his views, it was considered as muriatic acid combined with oxygen, and on that account it was denominated oxymuriatic acid. The French chemists, Gay-Lussac, and Thenard, about the year 1809, threw out a hint that oxymuriatic acid contains no oxygen in its composition; the same fact was asserted about the same time, or soon after, by Sir Humphry Davy; and in 1811, as the result of farther experiments, he concluded that it is a simple undecompounded substance, and from its greenish yellow colour he gave it the name of *chlorine*.

The nature and constitution of oxymuriatic acid are still the subject of controversy. The number, indeed, of those who unequivocally maintain the old doctrine is very small, and but few, we believe, have any hesitation in adopting the views of Scheele and Sir Humphry Davy. But whatever opinion be held, the description of the method of procuring it, and of its habitudes, must necessarily be the same.

Preparation.—Three parts of common salt by weight, one part of manganese in fine powder, and two parts of sulphuric acid, diluted with an equal quantity of water, being mixed together in a retort, and a moderate heat being applied, chlorine, or oxymuriatic acid gas, is evolved, and may be collected in jars over water. It may be obtained also by using the black oxide of manganese and liquid muriatic acid.

The nature of this process will be easily understood, according to the principles of the old doctrine, by recollecting that muriatic acid is assumed to be a compound of an unknown base with oxygen, and when it is expelled from the common salt by the superior affinity of the sulphuric acid for the soda, it unites with another portion of oxygen, derived from the manganese, and appears in a gaseous form. By the second process alluded to, the muriatic acid combines with part of the oxygen of the manganese, and is also expelled in the state of elastic fluid. But, considering chlorine as a simple substance, the process is thus explained: Muriatic acid is considered as a compound of hydrogen as its base, and chlorine as the acidifying substance, and in the above process the hydrogen of the acid combines with the oxygen from the metal, and forms water, while the chlorine is set free.

Properties.—Chlorine possesses the physical properties of common air; the colour is yellowish-green, the odour extremely disagreeable; it is unfit for respiration; and the weight of 100 cubic inches at mean temperature and pressure, exceeds 76 grains. Water, at the temperature of 60°, absorbs double its bulk of the gas, and acquires a strong astringent taste, a disagreeable smell, and a yellowish green colour.

This gas remains unchanged by heat or cold; but the aqueous solution freezes at the temperature of 40°.

Chlorine combines with oxygen, and the compound has acid properties; with hydrogen it forms muriatic acid; phosphorus when introduced into the gas is spontaneously inflamed; sulphur, when melted or sublimed in it, does not burn, but is converted into a volatile red liquor; an inflamed taper immersed in it gives out a dull red flame, with black thick smoke; and metallic substances, in a finely divided state, take fire in the gas, and burn spontaneously at the ordinary temperature of the air.

The compounds of chlorine with combustible substances are distinguished by the name of *chlorides*.

The most important property of chlorine is that of destroying vegetable colours, on account of which it is extensively employed in bleaching, and, by abridging the processes, has given a degree of certainty to that art, of which, till this fortunate application was made, it seemed unsusceptible.

Oxides.—Chlorine combines with oxygen in different proportions; one of these compounds is obtained by introducing a quantity of hyper-oxymuriate of potash into a small glass retort, and pouring over it as much muriatic acid, diluted with its bulk of water, as will cover it; with a gentle heat a gas is evolved, which should be collected over mercury. The constitution of this gas was discovered in 1811 by Sir Humphry Davy, who, from its bright yellow-green colour, gave it the name of *Euchlorine*. The smell has some resemblance to that of burned sugar; it is unfit for respiration, is absorbed by water, which takes up eight or ten times its own bulk, and becomes of a lemon-yellow colour; and 100 cubic inches exceed 74 grains in weight. The constituent parts of this gas are about 82 of chlorine and 18 of oxygen in the 100 parts.

This oxide of chlorine explodes with a very moderate heat, and its elements separate from each other with great violence, and with the evolution of light. Phosphorus introduced into the gas takes fire, and produces its decomposition with an explosion. This gas destroys vegetable colours; but first communicates to blues a tint of red.

Another oxide of chlorine, in which the oxygen is in larger proportion, has been examined. It is prepared by mixing together a very small quantity of hyper-oxymuriate of potash; the quantity of the salt ought not to exceed 40 or 50 grains, reduced to powder, and mixed with sulphuric acid till the whole is brought to the state of a dry paste. This paste is put into a small glass retort, which is to be immersed in hot water, but always kept under the temperature of the boiling point. A bright yellowish-green gas is soon given out, which is to be collected in jars in the mercurial apparatus.

This gas is of a brighter yellowish-green than the former, water absorbs nearly the same quantity, and becomes of a deep yellow colour. Without previously reddening vegetable blues, it destroys them in the moist state. It explodes when raised to the temperature of boiling water; phosphorus introduced into it produces an explosion followed by a splendid combustion; and 100 parts are composed of 53 of chlorine and 47 of oxygen.

Chloric acid.—Oxygen enters into combination in still larger proportion with chlorine, and the compound possesses acid properties. It is prepared by dissolving hyper-oxymuriate of barytes in water, and adding slowly and cautiously diluted sulphuric acid while any precipitate is formed. In this way, if the sulphuric acid be not added in excess, chloric acid is obtained in solution in water.

Properties.—The solution in water is colourless; it has no perceptible smell; with a moderate heat it may be concentrated, when it assumes the consistence of an oil; when the temperature is raised, it is partly volatilized without change, and partly decomposed into its constituents, chlorine and oxygen; 100 parts are composed of about 47 chlorine and 53 oxygen; and the saline compounds of this acid are denominated *chlorates*. According to the views of Berthollet this acid is called hyper-oxymuriatic acid.

Sect. VII. *Chloriodic Acid.*

It is a curious circumstance, and must be regarded as a singular anomaly in chemical combinations formerly known, that some of the substances which later discoveries have brought to light, perform in one case the part of a base, and in another that of the acidifying constituent. Chlorine itself, and iodine, with which it forms an acid, seem to possess this double property; but before detailing the character and habitudes of the acid, it is necessary to notice the discovery, and trace the history of iodine.

Iodine.—Iodine was discovered in 1811, by Courtois, a chemical manufacturer at Paris; but it was not till the end of 1813 that it was announced to the Institute of France. It was afterwards examined both by the French and British chemists.

Preparation.—A quantity of the kelp of commerce being reduced to powder, is dissolved in water; the solution is filtered and evaporated till the whole of the crystals of common salt are separated. The remaining liquid being mixed with sulphuric acid, is boiled for some time; and during this process muriatic acid and sulphuretted hydrogen gas are expelled. After boiling, the liquid is introduced into a small matrass or retort, and a quantity of black oxide of manganese, equal in weight to the sulphuric acid employed, is mixed with it; and with the application of heat a vapour of a violet colour is expelled and condensed in the form of a black shining substance on the sides of the receiver with which the retort communicates. The matter thus obtained is *iodine*.

Properties.—Iodine is in the form of scales, and sometimes crystallized; the odour is disagreeable, the taste acrid; it stains the skin of a yellow colour, and, like chlorine, destroys vegetable colours, but in an inferior degree. Iodine is fused at the temperature of 224°, and at 350° rises in vapour, which is of a deep violet colour, and from which the name is derived. Water dissolves a very small proportion, but acquires a peculiar smell, and becomes of an orange-yellow colour.

Iodine unites with oxygen, and the compound, which has acid properties, is white, semi-transparent, and solid, destitute of smell, but with a strong acid taste. When heated it melts, and when the temperature is raised separates into its constituent parts; deliquesces in the air, is very soluble in water, and the solution first reddens, and then destroys vegetable blues.

If a current of chlorine gas be passed into a vessel containing iodine, a combination takes place; and when the iodine is saturated, chloriodic acid is formed. This compound, the acid nature of which is not fully ascertained, is very volatile, deliquesces in the air, is soluble in water, and destroys vegetable blues.

From the chemical history of chlorine and iodine, a brief abstract of which has now been given, it would appear that these two remarkable substances possess some analagous properties, however distinct they are in others; but after all the researches which have been employed in tracing their nature and habitudes, experiments are perhaps still wanting finally to determine their true character.

Sect. VIII. *Fluoric Acid.*

Fluoric acid is so called because it is obtained from fluor spar, a well known mineral production in some of the mining districts in England, and long employed as a flux for metallic ores. Its remarkable property of corroding glass, when decomposed by sulphuric acid, was observed soon after the middle of the 17th century; and after various attempts by other chemists, the composition of fluor spar was ascertained by the experiments of Scheele, and found to be lime and a peculiar acid, which he distinguished by the name of *fluoric acid*.

Preparation.—Fluor, or Derbyshire spar, is reduced to fine powder, and is introduced into a retort of silver or lead, with twice its weight of concentrated sulphuric acid, and the retort being connected with a receiver of the same metal, cooled with a mixture of snow and salt, heat is applied to the retort, and the acid is driven off and deposited in the receiver in the liquid form.

Properties.—Liquid fluoric acid is transparent and colourless when it is kept at the temperature of the freezing point of water. It remains liquid at the temperature of 60°, but in the open air gives out copious suffocating fumes, and is soon dissipated. The gas is unfit for respiration and for the support of combustion. The liquid acid dropt into water produces a hissing noise, with the evolution of heat; when it touches the skin it corrodes it, and leaves a painful wound; and it reddens vegetable blues.

The singular property of corroding glass is one of the most remarkable characters of fluoric acid. When distilled in glass vessels, the acid combines with the siliceous earth of the glass, and appears in the form of elastic fluid, which, from its composition, is called silicated fluoric gas, of which 100 cubic inches weigh nearly 111 grains. When this gas is brought into contact with water it deposits a white gelatinous substance, which is hydrate of silica, or a compound of water and the earth, and the water becomes an acid solution.

The saline compounds of fluoric acid are denominated *fluates*.

Constituent parts.—The discovery of the composition of muriatic acid, and the comparison of fluoric and muriatic acids, which possess some analagous properties, have led to speculations of their constitution being somewhat similar. According to these views, fluoric acid is supposed to be a compound of hydrogen, and an unknown base, which has been called *fluorine*. But the existence of this base is only inferred from certain changes which are induced when those compounds of which fluoric acid forms a part are subjected to the operation of certain agents. In no experiment yet attempted has it been obtained in a separate state. Hydrogen, one of the supposed constituents, whatever be its origin, always appears; but the supposed fluorine is always in combination with some of the substances employed in the process. When, for example, fluoric acid is subjected to galvanism, hydrogen gas is given out at the negative end of the battery; and if wires of platina be used, the positive wire is coated with a substance of a chocolate appearance, which is supposed to be a compound of fluorine and the metal. Muriatic acid being exposed to the same action, undergoes decomposition, and also affords hydrogen from the negative wire, while the chlorine combines with the positive wire.

As the compounds of chlorine with those substances which have not acid properties are denominated *chlorides*, according to the same analogy the compounds of fluorine are called *fluorides*. The compounds of fluoric acid, and the alkalies and earths known by the name of fluates in the former views of their constitution, are to be considered, according to the new doctrine, as compounds of fluorine and the metallic base of those alkalies and earths which are to be noticed afterwards in detailing the chemical history of those bodies.

Sect. IX. *Boracic Acid.*

Boracic acid is one of the constituents of *borax*, a substance which has been long known in medicine and the arts, was separated from it by Homberg about the commencement of the 18th century, by distillation, and from him received the name of *narcotic* or *sedative salt*.

Preparation.—A quantity of borax of the shops, which is a compound of this acid and soda, is dissolved in hot water and filtered; sulphuric acid is gradually added till the liquid acquires a slight degree of acidity; and as the solution cools, the boracic acid is precipitated in shining scales. In this process the sulphuric acid unites with the soda, and sets free the boracic acid. The solid boracic acid is purified by washing with cold water, which carries off any adhering soluble salts.

Properties.—Thus obtained, boracic acid is in the form of silvery white six-sided scales, which have a greasy feel, a sourish taste, which afterwards gives the sensation of coolness, have no smell, and redden vegetable blues.

Boracic, when exposed to heat, froths up, owing to the separation of the water of crystallization, becomes a viscid paste, and is known by the name of calcined borax; subjected to a red heat it is converted into a hard transparent glass, which, without attracting moisture from the air, becomes opaque, but is otherwise unchanged; and, when re-dissolved in warm water, recovers, by cooling and crystallization, all its former properties.

Boracic acid is not very soluble in water, the solution has little taste, but it reddens the tincture of turnsole, and paper moistened with the solution burns with a green flame. The acid rises with the vapour of water when it is distilled in close vessels, and crystallizes in the receiver.

The saline compounds of boracic acid are called *borates*. It is employed in the arts, as in soldering, to assist the fusion of metallic substances, and it is of much importance to the mineralogist in promoting fusion by the blow-pipe.

Borone.—The base of boracic acid, which was long unknown, is supposed to be a substance in some measure analogous to carbone. If a quantity of boracic acid be fused and reduced to powder, and mixed with potassium, the metallic base of potash, and the mixture being in equal proportions introduced into an iron tube, which is to be gradually heated till it becomes slightly red, the acid is decomposed; and when the tube is cold the matter is to be washed out with water, and the potash formed being neutralized with muriatic acid, and the solution filtered, borone remains behind on the filter. It may be obtained also by subjecting the acid, slightly moistened, to the action of a galvanic battery; a dark coloured substance, which is borone, separates at the negative end of the battery.

Properties.—Borone is an opaque, olive-coloured powder, infusible, and is not volatile at a very high temperature. When it is strongly heated in contact with air, it undergoes combustion, and forms dry boracic acid. In oxygen gas it throws off bright sparks, and is coated with boracic acid; it burns with a white flame in chlorine gas, and a white substance lines the vessel, which is supposed to be the *chloride* of borone. By mixing together in a retort one part of fused boracic acid, with two parts of fluor spar, and 12 parts of sulphuric acid, a gas is obtained by the application of heat, which is found to possess acid properties. This gas, which must be collected in the mercurial apparatus, is colourless, smells like muriatic acid, has a very acid taste, and reddens vegetable blues; 100 cubic inches exceed 72 grains in weight, and water absorbs 700 times its own bulk. It is called *fluoboric* acid.

Sect. X. *Phosphoric Acid.*

When phosphorus is subjected to combustion in oxygen gas, the white fumes that arise, and are deposited in the state of white flakes, are phosphoric acid; which is therefore considered to be a compound of phosphorus and oxygen.

Preparation.—Phosphoric acid may be obtained by the decomposition of bones, of which it forms a constituent part, according to the process which has been already described in the preparation of phosphorus. When liquid phosphoric acid is evaporated, the acid remains behind in the solid state, and the whole of the water may be driven off by subjecting it to a red heat; it is then called phosphoric glass, and is transparent, colourless, and solid. It attracts moisture from the air, becomes viscid, and is very soluble in water. In the state of white flakes it dissolves with a hissing noise; the taste is acid, and it reddens vegetable blues.

Phosphoric acid is decomposed by means of charcoal, when exposed to a red heat; the carbone combines with the oxygen of the acid, and the phosphorus is separated. Sulphuric acid attracts the water from phosphoric acid, and leaves the latter behind in the state of a transparent viscid matter, or in that of glass, if strong heat be applied. Sulphurous acid is separated from its combinations by phosphoric acid; but the latter is separated by nitric and muriatic acids.

The component parts of this acid, according to the analysis of Lavoisier, are 60 of oxygen and 40 of phosphorus; the salts formed with it are denominated *phosphates*, and it is of much importance in many chemical operations.

Sect. XI. *Phosphorous Acid.*

Phosphorous acid is supposed to stand in the same relation to phosphoric acid that sulphurous acid bears to sulphuric, and is combined with a smaller proportion of oxygen. When small pieces of phosphorus are exposed to the air in a glass funnel placed in a bottle, they attract oxygen and moisture from the atmosphere, become liquid, and run down into the bottle. The liquid thus obtained is three times the weight of the phosphorus employed, and was formerly supposed to be phosphorous acid. It is thick and white, has an acid pungent taste, and reddens vegetable blues. But, from some late experiments on the product of this process, it appears to be a compound of phosphoric and phosphorous acid in equal proportions.

By the process proposed by Sir Humphry Davy, pure phosphorous acid may be obtained when phosphorus is sublimed through corrosive sublimate in powder in a glass tube; a colourless liquid comes over, which being mixed with water and evaporated to the consistence of syrup, is found to be a compound of phosphorous acid and water, in the proportion of nearly 81 parts of the former and 19 of the latter.

When this solution cools it becomes solid; the taste is strongly acid; and it has the property of changing vegetable blues to red. When it is strongly heated in open vessels it is inflamed, a copious evolution of phosphuretted hydrogen gas takes place, and what remains in the vessel is converted into phosphoric acid. During this process it is obvious the water is decomposed, its hydrogen unites with a portion of phosphorus, which passes off in the form of phosphuretted hydrogen gas, and the oxygen, combining with another portion of phosphorus, converts it into phosphoric acid. The saline compounds of phosphorous acid are called *phosphites*.

Sect. XII. *Carbonic Acid.*

The numerous combinations, and the remarkable discoveries in chemical science, which accompanied or followed the investigations of the nature of this substance, render it one of the most important of the acids. It was regarded by the ancients, from its noxious effects, as a pestilential vapour; Dr Hales gave it the name of fixed air, because it entered into the composition of solid bodies; and Dr Black, in his experiments on lime, magnesia, and the alkalies, proved that it is a peculiar substance different from common air, and that these bodies being combined with it, are deprived of their causticity, and rendered mild. Its acid properties were detected by Keir and Bergman, who called it aerial acid, and it received various other names, as mephitic acid, calcareous or cretaceous acid, from its deleterious effects, or from the substances from which it is obtained. The nature and constitution of this acid were finally ascertained by Lavoisier, who, according to the improved chemical nomenclature, distinguished it by the name of carbonic acid, from its base, carbone.

Preparation.—If a piece of charcoal in a state of ignition be immersed in a jar of oxygen gas, it burns with great brilliancy; and when the combustion has ceased, the air in the vessel has undergone a complete change. This new product being agitated with a little water introduced into the jar, combines with it, and exhibits acid properties; it is carbonic acid; but this acid may be collected in great abundance by putting a quantity of chalk, or limestone, or marble in the state of coarse powder, into a retort or mattrass with a bent tube attached to it, and adding diluted sulphuric, or nitric, or muriatic acids; a violent effervescence takes place by the evolution of gas, which may be collected in jars over water. The nature of this process is easily understood; the calcareous matter employed is a compound of carbonic acid and lime, but the sulphuric or other acids alluded to having a stronger affinity for the lime than the carbonic acid, the latter is set free, and passes off in the form of elastic fluid.

Properties.—Carbonic acid in the state of gas possesses the physical properties of common air; it is totally unfit for respiration or for the support of combustion; it has a peculiar sharp taste, and a faint, but agreeable smell; 100 cubic inches at the temperature of 60°, and when the barometer stands at 30 inches, weigh about 47 grains; and it reddens the tincture of turnsole, which is the proper test of this acid.

Water, at the temperature of 41°, absorbs its own bulk of the gas; but by artificial pressure it combines with a larger proportion, and in this way aerated waters are prepared, which thus acquire an acidulous taste. The whole gas is expelled by boiling, and it is also separated when the temperature of the water is reduced to the freezing point.

Carbonic acid is composed of nearly 18 parts carbone and 82 parts of oxygen; and the compounds of this acid, with the alkalies, some of the earths and metallic oxides, are known by the name of *carbonates*.

Exper. 1.—Fill a jar with carbonic acid gas, and immerse a lighted taper in it; the moment it comes in contact with the surface of the gas it is extinguished. The same experiment may be repeated several times in the same gas.

Exper. 2.—Fill a jar with carbonic acid gas, and after removing it from the shelf of the pneumatic apparatus, hold it for a few minutes in the same inverted position, and it will be found, when it is examined with a lighted taper, that the whole of the gas has escaped, and the air of the atmosphere has taken its place.

Exper. 3.—Place a lighted taper at the bottom of a deep bason or a wide jar, and having filled another jar with carbonic acid gas, invert it at a little height above the taper, and it will be as effectually extinguished as if water were poured upon it.

Carbonic acid gas is a very abundant natural production; it is formed in the processes of combustion and respiration, and during the fermentation of vegetable matters; and being specifically heavier than common air, it collects at the bottom of pits and caverns, and hence small quadrupeds, when they enter such places, are instantly suffocated, because they respire only this deleterious air. A cavern in Italy has been long known as being fatal to dogs, and hence it is called the *Grotto del Cani;* while men who breathe the stratum of common air in the upper part of the cavern escape uninjured. Fatal accidents have frequently happened to persons who have descended into large vats in which the process of fermentation has been carried on, or into pits or wells which have been long shut up. A single inspiration of this noxious gas seems to produce instant death. Similar accidents have befallen those who respire the fumes of burning charcoal in close apartments. In such cases, if life be not entirely extinguished, the most successful method of recovery recommended, is to dash cold water on the head and body, a practice which is usually adopted in northern regions, where the general use of charcoal is often followed by such fatal effects.

Sect. XIII. *Of Metallic Acids.*

Metallic substances unite with oxygen in different proportions, and the compounds thus formed are denominated oxides; but some of the metals combine with oxygen in larger proportion, and exhibit acid properties. Compounds of this nature are obtained from arsenic, tungsten, molybdena, chromium, and columbium.

1. *Arsenic acid.*—Arsenic combines with oxygen in two proportions, the first, which is the common arsenic of the shops, or the white oxide of arsenic, is called *arsenious acid.* It is usually in the form of a solid white cake, has an acrid taste, and is highly poisonous; is not very soluble in cold water, but hot water takes up a large proportion; and it reddens vegetable blues. The compounds of the alkalies with this acid are denominated *arsenites.*

Arsenious acid is converted into arsenic acid by repeated distillation with nitric acid, or it may be obtained by dissolving metallic arsenic in nitric acid, and after evaporating the solution to dryness, again to dissolve the residuum in water, and filtering the solution to evaporate again to dryness.

Properties.—Arsenic acid thus obtained is in the form of a white solid mass, has a sour and somewhat metallic taste; reddens vegetable blues, attracts moisture from the air, and when exposed to strong heat in a retort or crucible it corrodes the vessel, remains transparent, and is converted into a glass. This acid is more soluble in water than the former. The compounds of arsenic acid, with the alkalies, earths, and metallic oxides, are known by the name of *arseniates*.

2. *Tungstic acid.*—Tungstic acid is found in nature in two mineral substances, in the one of which it is combined with lime, and in the other, called wolfram, with iron and manganese. If one part of tungstate of lime and four parts of carbonate of potash be fused together, the mass is soluble in 12 parts of boiling water. To this solution, add nitric acid, which unites with the potash and precipitates tungstic acid. It may be obtained also by fusing wolfram with twice its weight of carbonate of potash. The fused mass being dissolved in boiling water, and filtered, affords, with the addition of nitric acid, a precipitate of tungstic acid, which, after being washed and dried, is in the form of a yellow powder, without taste, insoluble in water, and effecting no change on vegetable blues. The compounds of tungstic acid with the alkalies, which are soluble, and with the earths and metallic oxides which are insoluble in water, are denominated *tungstates*.

3. *Molybdic acid.*—This acid is usually obtained from a mineral substance, which is a compound of sulphur and molybdena. If a portion of the mineral substance be reduced to powder, introduced into a retort with six times its weight of nitric acid, and distilled to dryness, and this process being repeated several times, both the sulphur and the metal combine with oxygen and become acid. The sulphuric acid is separated by heating the mass in a crucible, and afterwards washing it with pure water; and molybdic acid, which is in the form of a white powder, having an acid metallic taste, remains. It is not very soluble even in boiling water; the solution is of a pale yellow colour, has no taste, but reddens paper stained with litmus, and is precipitated by sulphuric, nitric, and muriatic acids. The compounds with alkaline, earthy, and metallic bases, are called *molybdates*.

4. *Chromic acid.*—This acid is found in nature in combination with lead or iron. It may be obtained by reducing the chromate of iron to powder, mixing two parts with one of nitre, and subjecting the whole in a crucible for several hours to a strong heat. Dissolve the mass in water; the insoluble portion that remains is a mixture of oxide of iron and of the chromate yet undecomposed; add muriatic acid to separate the oxide, and mix the chromate with a fresh portion of nitre, which is to be subjected a second time to a strong heat; saturate the solution of potash and chromic acid, and evaporate the solution till the chromate of potash crystallizes. This salt being dissolved in water, the chromic acid is precipitated by muriate of barytes. The chromate of barytes which falls down, being well washed with water, is to be dissolved in nitric acid, and the barytes being precipitated by means of sulphuric acid, the solution is to be filtered and evaporated to dryness with a moderate heat. To separate the whole of the nitric acid, the addition of the water and the evaporation require to be repeated several times. The dry mass is chromic acid.

Chromic acid is of a deep red colour, has an acid strongly metallic taste, deliquesces in the air, and is soluble in water, from which it may be obtained crystallized of a ruby colour. When it is heated, part of the oxygen is expelled, and it is converted into the green oxide. When it is mixed with muriatic acid the mixture acquires the property of dissolving gold. It combines readily with the alkalies, and communicates an orange colour to the crystals. From this property it has derived its name. The compounds are called *chromates*.

The metal called columbium, discovered by Mr Hatchet, also forms an acid, an account of which may be found in his memoir published in the *Phil. Trans.* for 1802.

Sect. XIV. *Acetic Acid.*

Acetic acid, which is produced in one stage of the fermentation of vegetable matters, was known, at least in an impure form, and under the name of *vinegar*, in the earliest ages of the world. When vinegar is distilled it is distinguished by the name of acetous acid; and when it is still farther purified from those substances with which it is contaminated, and concentrated by separating the water, it is radical vinegar, or acetic acid.

Vinegar, which is formed when vegetable infusions become sour, is of a reddish yellow colour, an agreeable smell, and pleasant acid taste; when it is distilled with the heat of boiling water, it becomes quite colourless and the taste is more strongly acid. This is distilled vinegar or acetous acid; and it may be still farther concentrated by exposing it to cold by which the water is frozen.

Acetic acid is prepared by the decomposition of some of those compounds of which it forms a part. If a quantity of acetate of copper be reduced to powder, and put into a retort and distilled, a colourless and nearly insipid liquid first comes over, and afterwards a very pungent acid. This acid requires a second distillation to purify it from a greenish tinge, arising from a portion of the copper; it is then transparent and colourless.

Acetic acid may be also obtained by the distillation of three parts of acetate of potash and four parts of sulphuric acid. The sulphuric acid combines with the potash and the acetic acid being set free passes over into the receiver, where it crystallizes. To purify it from any remains of sulphuric acid it is subjected to a second distillation with a mixture of acetate of barytes.

Properties.—Acetic acid, when pure, is perfectly colourless, has a fine aromatic odour when in the state of distilled vinegar; but it is less agreeable when more concentrated, as when it is of the specific gravity of 1.08. Acetic acid is very volatile, reddens vegetable blues, is pungent and acrid, and reddens and corrodes the skin.

The constituent parts of acetic acid, are hydrogen, carbone, and oxygen; it is decomposed by the action of sulphuric and nitric acids, and its saline compounds are called *acetates*.

Of Acids.

Acetic acid is of great importance on account of its extensive application, not only to numerous purposes of domestic economy, but also of the arts.

Sect. XV. *Benzoic Acid.*

This acid derives its name from *styrax benzoe*, a tree which is a native of Sumatra; the resinous matter obtained from this tree is called *benzoin*; and the acid substance prepared by sublimation was called flowers of benzoin.

Preparation.—The common method of preparing this acid, is to introduce a quantity of coarsely powdered benzoin into an earthen pot, and covering the pot with a cone of thick paper, to apply a moderate heat; the acid is sublimed and is deposited on the paper. But it may be obtained by digesting benzoin in sulphuric acid; and in this process the acid is purer, and in finer crystals.

Properties.—Benzoic acid is a fine white matter in the form of needles, which have some degree of ductility; the taste is acrid, pungent, and bitter; the odour when heated is aromatic; it has but a feeble effect on some vegetable blues; but, when it is hot, reddens the tincture of turnsole.

Exposed to a moderate heat, it melts and becomes soft and spongy; with a stronger heat it is sublimed and exhales a white acrid vapour; and when set fire to, burns without leaving any residuum. It undergoes no change in the air; is little soluble in cold water; but 25 parts of boiling water dissolve about one part of the acid. Benzoic acid is soluble in some of the stronger acids, but is separated from the solution by the addition of water; it consists of hydrogen, carbone, and oxygen; and the saline compounds are called *benzoates*.

Benzoic acid exists in some animal secretions, particularly those of the horse and cow, and is supposed to be derived from the grass or hay which forms part of their food. The peculiar odour of *anthoxanthum odoratum*, and *asperula odorata*, which are both known in common language under the name of sweet-scented grass, is owing to benzoic acid; and from the first of these plants hay derives its fine smell.

Sebacic acid—from the later researches of chemists, seems to be of the same nature as benzoic acid; it is prepared by distilling hog's lard or tallow, washing the product with hot water, and after separating the water by dropping into it a solution of sugar of lead, a flaky precipitate is obtained; which being collected and dried, and mixed with sulphuric acid, a melted substance like fat, when heat is applied, swims on the surface. This matter being separated and washed, is boiled with water in which the whole is dissolved; and when it cools, crystals in the shape of needles, which are sebacic acid, are deposited. It requires a higher temperature than benzoic acid to sublime it; but it approaches so nearly to the latter in its other properties, that it is supposed to be contaminated with some substance the nature of which is unknown.

Sect. XVI. *Succinic Acid.*

This acid derives its name from the Latin word which signifies *amber*, because it is obtained from that substance.

2

Preparation.—Introduce into a retort a quantity of powdered amber, so that the body of the retort shall be half full; cover the amber with dry sand, apply a receiver which much be secured with a lute, and distil with a moderate sand heat. The first product is an insipid phlegm, which is succeeded by a portion of weak acetic acid; and, last of all, a substance is deposited in the neck of the retort, which is succinic acid. To separate the acid from some oil with which it is contaminated, it is dissolved in hot water, filtered through cotton, which should be previously moistened with oil of amber, and then crystallized by slow evaporation.

Properties.—The crystals of this acid are transparent, white, and shining, and of a prismatic form; the taste is acid, and they redden the tincture of turnsole.

Succinic acid requires a considerable heat for its sublimation; it is not very soluble in cold water; but two parts of boiling water are sufficient for its solution, from which, on cooling, the greater part crystallizes. It is soluble in sulphuric and nitric acids with the aid of heat; is not decomposed by muriatic acid, but assisted by heat forms a jelly.

The constituent parts of succinic acid are carbone, hydrogen, and oxygen; its saline compounds are denominated *succinates*, and it is of great importance in separating iron from its solutions.

Sect. XVII. *Moroxylic Acid.*

An exudation of a saline nature, in small grains of a a yellowish brown colour, was detected on the bark of the white mulberry tree; and being examined by Klaproth, was ascertained to be a compound of lime with a peculiar acid; and he gave it this name because it was obtained from the wood of the mulberry tree.

The acid is separated by dissolving the salt in water, and adding acetate of lead, and mixing the precipitate with sulphuric acid diluted with water, a sulphate of lead is formed, while the moroxylic acid is set free and remains in the solution. It may be obtained crystallized by evaporating the liquid, and is still farther purified by sublimation. It has somewhat the taste of succinic acid, remains unchanged when exposed to the air, and is soluble in water. This acid is composed of hydrogen, carbone, and oxygen, and its saline compounds are called *moroxylates*.

Sect. XVIII. *Camphoric Acid.*

Camphor, a well known substance, which is the production of *laurus camphora*, a native of the East Indies, affords this acid, and gives its name.

The acid is prepared by distilling in a retort, with a sand heat, one part of camphor and eight parts of nitric acid; the same process is repeated with fresh portions of the acid three times, and after the third distillation, when the apparatus cools, crystals of camphoric acid, about one-half of the camphor employed, are formed. These crystals being separated from the nitric acid, are washed and dried.

Properties.—The acid thus prepared is in the form of snow-white crystals, which effloresce in the air; the smell resembles saffron; the taste is slightly acid and bitter, and it reddens vegetable blues; it is not very soluble in cold water, but boiling water dissolves about a twelfth part of its weight. With a moderate heat it melts and sublimes, but when it is placed on burning coals it gives out thick aromatic fumes, and is totally dissipated; it is soluble in sulphuric and muriatic acids; in nitric acid when heated it becomes yellow, and is also dissolved. The constituent parts of camphoric acid are hydrogen, carbone, and oxygen, and its saline compounds are called *camphorates*.

Sect. XIX. *Oxalic Acid.*

Oxalic acid exists, ready formed, in *oxalis acetosella*, or wood-sorrel, and some other plants allied to it, and hence it derives its name. Being obtained from sugar, it was called saccharine acid, or the acid of sugar.

Preparation.—Put an ounce of white sugar into a retort with three ounces of nitric acid, apply heat till the liquor boils, and the whole of the nitrous gas is driven off; the liquid in the retort becomes of a reddish brown colour, and then an additional quantity of nitric acid may be added, and the boiling continued till the fumes cease; the liquid is then poured out into a shallow vessel, and when it cools crystals are formed, which being collected and dried on blotting paper, are to be dissolved in distilled water, and again evaporated and crystallized. By a similar process, oxalic acid may be obtained from other vegetables, and from some animal substances, as gum arabic, alcohol, and honey.

Properties.—Thus prepared, oxalic acid is white and transparent, in the form of four-sided prisms, with two-sided summits; has a strong sharp taste, and reddens vegetable blues; it is soluble in twice its weight of cold water, and in its own weight of boiling water; and by exposure to moist air it is not changed, but effloresces when the air is dry.

It is volatilized by heat, partly in a liquid and partly in a solid and crystalline form; and when the temperature is raised, it is partially decomposed. Oxalic acid is decomposed by sulphuric acid, with the aid of heat, and charcoal is deposited; by means of nitric acid at the boiling temperature, it is converted into water and carbonic acid. These changes lead to a knowledge of its constituent parts, which analysis points out to be 77 of oxygen, 13 of carbone, and 10 of hydrogen; the saline compounds are called *oxalates*.

Oxalic acid, from its strong affinity for lime, is one of the best tests of that substance, the minutest quantity of which it separates from all its other combinations.

Sect. XX. *Tartaric Acid.*

Tartaric acid derives its name from tartar, the substance from which it is extracted, and it was first procured in a separate state by the celebrated Scheele.

Preparation.—Tartar, or cream of tartar, is dissolved in water, and powdered chalk is added till effervescence ceases, and the liquid no longer reddens vegetable blues; a precipitate is formed in the state of white powder, which being separated by filtration is well washed, and a quantity of sulphuric acid, equal in weight to the chalk employed, is poured upon it and allowed to remain for a day or two, during which the mixture should be occasionally stirred; the liquid being afterwards filtered and evaporated, crystals of tartaric acid are formed.

Properties.—Crystallized tartaric acid is white and transparent, in the form of four-sided prisms, and containing about fifteen parts of water in the 100; it is not affected by exposure to the air; at the temperature of boiling water it becomes liquid; but when the heat is increased, it concretes into a hard mass on cooling, and seems to have undergone some change, for it has acquired a deliquescent property.

The taste is sharp and pungent, when it is diluted with water it resembles the taste of lemon-juice, and it strongly reddens blue vegetable colours; it is very soluble in water, and when much diluted is liable to decomposition. The constituent parts of this acid are oxygen, carbone, and hydrogen, and its saline compounds are denominated *tartrates*.

Sect. XXI. *Citric Acid.*

The sour taste of lemons and oranges is owing to citric acid; but as it exists in these fruits it is mixed with water and mucilage, from which it must be separated to procure it in a state of purity.

Preparation.—Having filtered a quantity of lemon juice, add powdered chalk as long as any effervescence continues; wash the white precipitate, which is a compound of citric acid and lime, with warm water, and add diluted sulphuric acid in sufficient quantity to saturate the lime; boil it for a few minutes, and, when cool, filter it. The filtered liquor being cooled and evaporated, affords crystals of citric acid.

Properties.—The crystals of citric acid are in the form of rhomboidal prisms, have a strong acid taste, with a slight odour of lemons, redden vegetable blues, and are soluble in less than their own weight of water.

Citric acid effloresces in a dry air, melts rapidly when exposed to heat, and frothing up, is reduced to the state of charcoal; it is converted into acetic acid by the action of sulphuric acid, and by nitric acid partly into acetic acid and partly into oxalic acid.

The constituent parts of citric acid are oxygen, carbone, and hydrogen; and the saline compounds are known under the name of *citrates*.

Sect. XXII. *Malic Acid.*

Malic acid exists in greatest abundance in the juice of apples, and hence the name is derived; but it is also found in other fruits, and in some it is nearly in equal proportion with citric acid, as in the cherry, gooseberry, and strawberry.

Preparation.—Bruise a quantity of sour apples, squeeze out the juice, and filter it through a linen cloth; saturate this juice with potash, and continue to add sugar of lead, dissolved in water, as long as any precipitation continues. The acetic acid of the sugar of lead combines with the potash and remains in the liquid, while the malic acid uniting with the lead, and being insoluble, falls to the bottom. After the precipitate is well washed with water, add diluted sulphuric acid, which combines with the lead and falls to the bottom, and the malic acid is set free, and remains in the liquid. By evaporation it may be obtained in the solid form, but it does not crystallize.

Properties.—In the state of liquid it is colourless when first prepared, but afterwards becomes brown by keeping; the taste is strongly acid; it is very soluble in water, and it reddens blue vegetable colours.

Malic acid is readily decomposed by heat; it exhales a thick acrid vapour, and leaves behind a bulky mass of charcoal; it is decomposed by the stronger acids; its constituent parts are oxygen, hydrogen, and carbone, and the saline compounds are denominated *malates*.

A pure and nearly colourless malic acid has been extracted from the juice of house-leek, in which it exists in combination with lime.

Sect. XXIII. *Saclactic Acid.*

This acid has been otherwise called mucous acid, because it is obtained from gum arabic and some other mucilaginous substances.

Preparation.—If one part of gum arabic be introduced into a retort with two parts of nitric acid, and a moderate heat be applied, while a little nitrous gas and carbonic acid gas are disengaged, a precipitate in the form of white powder, which is saclactic acid, falls down when the mixture cools; but as it is still impure, it requires to be digested several times in diluted nitric acid, to separate some portion of oxalate of lime; and a compound of gum and lime, which also adheres to it, may be separated by dissolving the acid in boiling water; when the water cools, pure saclactic acid is deposited. If sugar of milk be substituted for gum, the secondary processes are not necessary.

Properties.—The acid in the state of powder is white and gritty, with a weak acid taste. It is readily decomposed by heat, and yields an acid liquor, which crystallizes, on cooling, in the form of needles; a small portion of an acrid caustic oil, of a blood red colour, carbonic acid gas, and carburetted hydrogen gas, while a bulky mass of charcoal remains behind. It is sparingly soluble even in boiling water; the solution has an acid taste, and reddens the tincture of turnsole.

This acid is composed of oxygen, carbone, and hydrogen, and its saline compounds are denominated *saccolates* or *saclactates*.

Sect. XXIV. *Suberic Acid.*

Suberic acid derives its name from the word *suber*, which is the Latin name of cork, a singular production of a species of oak, the *quercus suber*, Lin. or cork-tree.

Preparation.—Suberic acid is obtained by grating down a quantity of clean cork, introducing it into a retort, and adding six parts of nitric acid. When the action of the acid ceases, evaporate the mixture to the consistence of an extract, pour over it hot water, and digest the mixture for some time in a sand heat; after cooling, a substance like wax appears on the surface, and a white flocculent matter falls down. These substances being removed, and the remaining liquid being concentrated by evaporation, suberic acid is precipitated in the form of powder. It has been observed, that crystals of oxalic acid are sometimes formed towards the end of the process. The powder is purified by washing in cold water.

Properties.—Suberic acid thus prepared has the whiteness of starch, with a slightly acid taste; it is not very soluble in water; it melts by the application of heat, and crystallizes in the shape of needles on cooling. It may be sublimed in close vessels, and it is condensed in the form of needles.

The constitution of this acid is probably the same with other vegetable acids, and its saline compounds are called *suberates*.

Sect. XXV. *Lactic Acid.*

In examining the spontaneous changes which take place in milk, Scheele discovered that it contains a peculiar acid, to which he gave the name of *lactic acid*.

Preparation.—If a quantity of whey of milk be evaporated to dryness, the extract obtained is composed of lactic acid, lactate of potash, muriate of potash, and phosphate of lime, beside a portion of animal matter. This mass being dissolved in alcohol, and mixed with alcohol, to which is added a seventy-sixth part of its weight of concentrated sulphuric acid, till the sulphuric acid appear in excess in the solution, a precipitate of sulphate of potash takes place. For the purpose of separating the other acids it is digested with carbonate of lead, till the liquid become of a sweetish taste. The sulphuric, phosphoric, and muriatic acids are thus separated, and the lactic acid, in combination with lead, remains in the solution. The lead may be precipitated by passing a current of sulphuretted hydrogen gas through the liquid, which is then to be digested over quicklime, till the whole of the animal matter is separated, and lactic acid, muriatic acid, and lime, remain in the solution. To a portion of the liquid, oxalic acid is to be added to separate the lime, and this portion being saturated with carbonate of silver, and added to the remaining liquid, separates the muriatic acid; the addition of oxalic acid precipitates the lime, and leaves the lactic acid in the solution. By evaporating to dryness, and again dissolving in water, it may be still farther purified from any remains of oxalate of lime.

Properties.—Lactic acid is of a brownish yellow colour, with a sharp sourish taste; it is never crystallized, but when evaporated to dryness has the appearance of a varnish which is deliquescent in the air. It froths up when heated, gives out a sour smell, and leaves behind a bulky mass of coal. The saline compounds of this acid, which are called *lactates*, are soluble in water, but do not crystallize.

Sect. XXVI. *Laccic Acid.*

This acid is obtained from the substance called *lac*, which is collected in the East Indies, and is the production of insects. Two kinds of lac are mentioned, *white lac* and *stick lac*.

Preparation.—A portion of white lac being subjected to heat, just sufficient to melt it, gives out about one-fourth of its weight of a reddish watery liquid, which, being filtered and purified, is found to be laccic acid. But by another process, stick lac is reduced to powder, and digested in water as long as any colour is given out; the aqueous solution being evaporated to dryness, the residuum is digested

Of Acids.

ed in alcohol; and this solution being also evaporated, the dry residuum is digested in ether, which latter being evaporated, leaves behind a mass of a light yellow colour, and of the consistence of syrup. This mass being redissolved in alcohol, to which some water is added, a portion of resin is precipitated.

The laccic acid, combined with a little lime and potash, remains in the liquid; the acid may be separated by means of lead; and the precipitate formed being decomposed by sulphuric acid, the laccic acid remains behind.

Properties.—Laccic acid crystallizes in the form of small needles; it is of a yellowish colour, with an acid taste, and is soluble in water; its constituent parts are probably similar to the other vegetable acids.

Sect. XXVII. *Gallic Acid.*

Gallic acid is obtained from nut galls, an excrescence which is produced on some species of oak, and hence it derives its name. The same acid exists in the bark and wood of other plants.

Preparation.—Reduce a quantity of nut galls to coarse powder, and add six parts of pure water; let the infusion macerate for two weeks, at a temperature between 70° and 80°; and after being filtered put it into a large glass, or earthen vessel, and expose it to the air, that it may evaporate slowly; a glutinous pellicle forms on the top, and mucous flakes are precipitated. The solution has now no longer an astringent, but an acid taste. At the end of two or three months a brown crust, covered with shining crystals of a yellowish grey colour, is formed on the sides of the vessel. These crystals were also found under the thick pellicle which covered the liquid, which being decanted, alcohol is added to the precipitate, the pellicle, and the crystalline crust, and with the assistance of heat the alcohol dissolves the crystallized acid, without touching the mucilage; and after the evaporation of this solution, the gallic acid is obtained in small shining crystals, of a yellowish grey colour.

By another process recommended by Deyeux, a French chemist, this acid may be more readily prepared. Nut galls being reduced to powder, are introduced into a large glass retort, and heat being slowly and cautiously applied, a large quantity of brilliant silvery crystalline plates, which are gallic acid, is sublimed. But in this process the heat applied must be very moderate, and must be withdrawn before an oil is disengaged, which instantly dissolves all the crystals.

A method of preparing gallic acid, proposed by Sir Humphry Davy, is by boiling together carbonate of barytes, with a solution of gall nuts; the liquid becomes of a bluish green colour, and by dropping into it diluted sulphuric acid, grows turbid, sulphate of barytes is deposited, and after the liquid is filtered, if the earth be fully saturated, a solution of pure gallic acid is obtained.

A fourth process suggested for preparing gallic acid is, by drying the crystals obtained by the first process, and subliming them in a glass vessel. In this way pure crystals of the acid are obtained, while the tannin, with which they are often contaminated, remains behind.

Properties.—Gallic acid, in a state of purity, is crystallized in transparent octohedrons, or brilliant plates; the taste is sharp and pungent, and the odour, when heated, is somewhat aromatic, but disagreeable. It is not affected by exposure to the air; it is soluble in 12 parts of cold water, and in two-thirds of its weight of boiling water; with a moderate heat, it rises into vapour, but every time it is sublimed it is partially decomposed. By repeated distillations gallic acid is converted into carbonic acid, carburetted hydrogen, and water, products which sufficiently indicate its constituent parts. It is decomposed by concentrated sulphuric acid, and charcoal is deposited.

The constituent parts of gallic acid are oxygen, carbone, and hydrogen, but the carbone is in larger proportion than in the other vegetable acids. The saline compounds of this acid are called *gallates*.

Gallic acid is peculiarly valuable as a test, or reagent, to discover metallic substances which are held in solution along with other bodies: its effects on metallic oxides are very various; with different metals it affords different coloured precipitates; and the more readily the metallic oxides give up their oxygen, the greater is the change produced on them.

Sect. XXVIII. *Prussic Acid.*

Prussic acid is one of the most important both to the chemist and manufacturer. It has been supposed that the ancients employed Prussian blue in painting; but it appears that the beautiful colours which are admired in the paintings of Herculaneum are derived from ultra-marine blue, and the smalt or azure of cobalt.

The discovery of Prussian blue was accidental. About the beginning of the 18th century, Diesbach, a chemical manufacturer of Berlin, wishing to precipitate a decoction of cochineal, alum, and green vitriol, by means of an alkali, borrowed from Dippel some potash on which he had distilled several times the animal oil which bears his name; but instead of a red precipitate, as he expected, a beautiful blue matter was thrown down by the addition of the alkali. Considering the ingredients which were brought into action, he found that he could produce at pleasure the same substance, which afterwards became an object of commerce, and from the place where it was discovered was called *Prussian blue*.

Preparation.—An extemporaneous alkali is prepared by detonating four ounces of nitre and an equal quantity of tartar, to which four ounces of bullock's blood, well dried, are to be added; calcine the whole with a moderate heat, in a covered crucible, having a small opening in the top, till the smoke or flame ceases to blacken any white body exposed to it. Towards the end of the process, increase the heat, till the crucible shall be moderately red. Throw the red-hot matter into four pounds of water, and boil it for half an hour, and having poured off the first water add another quantity, and boil again, and repeat the same operation till the liquid comes off insipid. All the quantities of water being collected together, are boiled down to four pounds; and this liquid has been called blood-ley, or phlogisticated alkaline ley.

Prepare a solution of two ounces of sulphate of iron, and eight ounces of alum, in four pounds of boiling water, and mix it with the solution of blood-ley while both are boiling hot; a great effervescence takes place, the liquid becomes greenish, inclining more or less to blue, and a precipitate is formed of the same colour. This precipitate being separated, the colour is heightened by adding muriatic acid till it no longer increases the intensity of the blue colour; it is then washed with water and slowly dried. Such was the process employed in the preparation of this remarkable substance before its nature and constitution were understood.

The researches of all the most celebrated chemists were directed to the discovery of the constituent parts of Prussian blue. Macquer, Bergman, and Scheele were particularly occupied in its investigation; and by the labours of the latter a method of separating the colouring matter was discovered.

Two parts of Prussian blue reduced to powder, one part of red oxide of mercury, and six parts of water, were boiled and continually stirred for a few minutes in a glass vessel; the mixture assumed a yellow-greenish colour; the whole was put on a filter, and two parts more of boiling water to wash it completely were poured on the residuum. This liquid is a solution of mercury combined with the colouring matter, which has a metallic taste, and is neither precipitated by acids nor alkalies. Pour this liquid into a glass vessel, after being filtered while it is hot, and when it is cooled add to it in a bottle two ounces of iron filings, and six or seven drachms of sulphuric acid; shake the mixture well for a few minutes, when it becomes black by the reduction of the mercury; the liquid then loses its metallic taste, and gives out the peculiar odour of the colouring matter. Decant the clear liquid into a retort, and, having adapted a receiver, distil with a gentle heat till one-fourth part of the liquid passes over. The liquid in the receiver is commonly mixed with a portion of sulphuric acid, from which it may be separated by a second distillation, with the addition of a little powdered chalk. The prussic acid is then obtained in a state of purity.

The following process is recommended by Gay-Lussac. A prussiate of mercury is prepared by boiling together red oxide of mercury and Prussian blue, and by evaporating the solution the salt may be obtained in crystals, which are to be introduced into a small tubulated retort, with a portion of muriatic acid, but less in quantity than what is required for the decomposition of the metallic salt. Let a glass tube, about two feet long, and about half an inch in diameter, be fitted to the beak of the retort, and fill the first third part of the tube with small fragments of marble, and the remainder with dry muriate of lime. The purpose of the marble is to combine with any portion of muriatic acid that may be driven over, and of the muriate of lime to retain the water. Let the tube terminate in a small receiver, which should be immersed in a freezing mixture of snow and salt; a moderate heat is then to be applied to the retort, and the acid is expelled and condensed on the marble, from which it may be separated and driven along the tube into the receiver by heat. *An. de Chim.* 95-145.

Properties.—Prussic acid is a colourless transparent liquid, with the odour of peach flowers, or of bitter almonds; the taste is sweetish at first, but soon becomes acrid and hot; it has no effect on vegetable blues; it has a strong tendency to assume the gaseous form, and is therefore soon dissipated when exposed to the air in open vessels. It boils at the temperature of 80°, and freezes at 5°.

When subjected to a high temperature it is decomposed, and by the action of light it is converted into carbonic acid, ammonia, and carburetted hydrogen gas. It combines with difficulty with alkalies and earths, which are readily decomposed by the action of carbonic acid, and are even acted upon by the portion that exists in atmospheric air. But this acid has the greatest tendency to form triple salts with alkaline and metallic bases, and these combinations are more permanent and fixed than the simple alkaline prussiates.

The constituent parts of prussic acid are carbone, azote, and hydrogen.

Prussous acid.—This acid is supposed to contain a smaller proportion of oxygen in its composition, but, according to others, it contains a portion of sulphur in addition to the constituent parts of prussic acid, or as a substitute for the hydrogen.

The acid which combines with a double base, forming the triple prussiates, is also supposed to be different in its constitution from prussic acid. According to the views of those who have investigated the nature and properties of these salts, this acid is a compound of oxide of iron and prussic acid.

Chap. X. Of Alcohol, Ether, and Oils.

The constituent parts of alcohol, ether, and oils, are carbone and hydrogen chiefly; but in some a triple compound of carbone, hydrogen, and oxygen exists, although the latter is not in such proportion as to exhibit acid properties, or these properties are concealed by the proportions of the other ingredients. These bodies are closely allied to the vegetable acids in their constitution, and some of them are to be considered as valuable instruments of chemical analysis. It is therefore of importance that their properties should be early known.

Sect. I. *Alcohol.*

When vegetable matters are subjected to the vinous fermentation, the fluid is converted into wine or beer; and this wine being distilled, the product of the distillation is a transparent liquid called alcohol, spirit of wine, or ardent spirit, which differs in flavour, colour, and strength, according to the nature of the materials from which it is obtained; and it is distinguished by different names. Brandy is the product of the distillation of the fermented juice of the grape, rum of that of the sugar-cane, and whisky of that of farinaceous substances. All these products are composed of alcohol, or pure spirit of wine, water, and an oily or resinous matter, to which the peculiar flavour is owing. No allusion is made to ardent spirit in the writings of the Greeks or Romans; it is supposed that it was known during the dark ages; but the preparation of it from wine, and even the discovery of alcohol, or pure spirit itself, is ascribed to Arnold de Villa Nova, who lived about the end of the 13th century, and was professor of chemistry at Montpellier.

Ardent spirit, as it is extracted from wine or beer, is a mixture of alcohol, water, and some oily and colouring matter. To purify it from these substances it is distilled several times; after the first distillation, it is called rectified spirits, but in this state it still retains a portion of water. To separate this portion it is to be distilled in a water bath till one-fourth of the quantity has passed over, and the same process is to be repeated several times, taking only the first half of the product. The different products being mixed together, the whole is to be distilled with a gentle heat, till the first half of the liquor passes over.

The alcohol, after these repeated distillations, is still combined with a portion of water. Various processes have been proposed to separate this water by the addition of substances which have a strong attraction for the water, and are nearly insoluble in the alcohol. For this purpose common salt of tartar, after being exposed to a red heat and reduced to powder, has been employed. But the alcohol is obtained in a state of greater purity by using muriate of lime which has been subjected to a red heat and reduced to powder; the salt while it is yet warm is to be put into a retort, and the strongest rectified spirits, nearly equal in weight, is poured over it at repeated intervals. Great heat is produced, arising, no doubt, from the condensation of the water in the saline compound; a sand heat is then applied to the retort, and the liquid being boiled the product is admitted into a receiver. The salt, with the alcohol, forms a thick solution, and the portion which first passes into the receiver is returned to the retort, and the whole is distilled to dryness.

Properties.—Alcohol is a transparent colourless liquor, with an agreeable smell, and a warm acrid taste; its powerful intoxicating effects are well known. The specific gravity of rectified spirits is rarely under .837, water being reckoned 1.000, and the strongest that can be obtained by distillation is about .820; but by the process just described for the separation of the water it has been reduced to .792 at 68°. It boils at 176°, and, when very strong, at a lower temperature, and rises into vapour in the vacuum of an air-pump at the temperature of 56°; it remains fluid when reduced as low as 91° below 0°. The freezing of alcohol at the temperature of 110° below 0° has been stated, but as no account of the process, has been published, the fact is still involved in some degree of mystery. When alcohol is passed through a red hot porcelain tube, it undergoes decomposition, and is converted into carbonic acid gas, carburetted hydrogen gas, and water. These products indicate the component parts of alcohol to be hydrogen, carbone, and oxygen, and in the following proportions, hydrogen 14, carbone 52, and oxygen 34.

A small portion of phosphorus dissolves in alcohol, which gives out the odour of phosphuretted hydrogen gas. If this solution be dropt into water in a dark place, a luminous appearance is produced on the surface of the water. Sulphur and alcohol unite only in the state of vapour, which being condensed, a reddish coloured liquid is formed; when the alcohol is very strong it dissolves a small portion also in the liquid state; when water is added to the solution the sulphur is precipitated. Sulphuric, nitric, and muriatic acids decompose alcohol, and afford a very peculiar product called ether.

Alcohol combines with water in all proportions, and the increase of temperature which is always produced, shews that a condensation of the two liquids takes place. The density varies according to the proportion of the alcohol and water which are mixed together; and, in consequence of this variation, it becomes an important object, both for the purpose of commerce and revenue, to be able to ascertain the quantity of alcohol in spirituous liquors of different specific gravities. With this view, instruments called hydrometers have been invented, and elaborate sets of tables have been constructed.

Alcohol is a valuable instrument of chemical analysis, because many saline substances which are soluble in that liquid may be separated from salts or from other extraneous bodies, that are insoluble.

Sect. II. *Ether.*

Alcohol is decomposed by different acids, and a fragrant volatile liquid, very different in some of its properties either from the alcohol or acid employed, is obtained. *Ether,* the product of this decomposition, is different in its properties, and has received different names, according to the acids which are employed in its preparation, as sulphuric ether, nitric ether, &c.

1. *Sulphuric ether.*—The mode of preparing sulphuric ether was published at Nuremberg about the year 1540; but it was not till the beginning of the 18th century that its nature and properties were much known.

Preparation.—Equal parts of concentrated sulphuric acid and alcohol are put into a retort, or, to avoid the violent action, let the acid be added at repeated intervals; the retort is to be placed in a sand-bath previously heated, and connected by means of an adopter with a tubulated receiver; to the tubulure of the receiver a glass tube twice bent at right angles is to be luted, and its extremity inserted in a small vessel of water or mercury. By this tube the elastic fluids which are not condensed are allowed to escape. The receiver itself must be kept cool by the application of wet cloths. When the liquid boils the ether is produced, and passes over into the receiver, and the boiling is continued till white fumes arise in the retort, or the smell of sulphurous acid is perceived. The receiver is then to be removed. The ether is generally contaminated with sulphurous acid; and for its purification a portion of the black oxide of manganese is put into a bottle with the ether and kept for 24 hours, during which time it is occasionally shaken; the clear liquid is then separated and distilled in a water-bath till one half come over. A portion of slaked lime also is recommended by some for the separation of sulphurous acid.

Properties.—Sulphuric ether is a transparent colourless fluid of a very fragrant smell, and a hot pungent taste; it is lighter than alcohol, the specific gravity being only 0.758, or when farther rectified

Of Alcohol, &c.

0.715. It boils in the open air at the temperature of 98°, and in the vacuum of an air-pump at so low a temperature as 20° below *zero;* it burns readily in the open air, and with a copious white flame. When the temperature is reduced to 46° below *zero*, it freezes and crystallizes. When passed through a red hot porcelain tube, carburetted hydrogen gas is obtained by its decomposition.

The constituent parts of sulphuric ether are stated at 14 of hydrogen, 68 of carbone, and 18 of oxygen.

Ether dissolves a small quantity of phosphorus; the solution is transparent, but becomes milky by the addition of alcohol; it also dissolves a small portion of sulphur, and the solution affords the smell and taste of sulphuretted hydrogen gas. Sulphuric acid converts ether into a peculiar liquid, called the sweet oil of wine.

2. *Nitric Ether.*

Nitric acid has a much more violent action than sulphuric acid on alcohol, so that it is necessary to moderate the effects of the two liquids by cooling the mixture; the first easy process proposed for the preparation of nitric ether was published in 1742, by Navier, a physician of Chalons.

Preparation.—Twelve parts of pure alcohol are introduced into a strong bottle, which is immersed in cold water or surrounded with ice. To this eight parts of concentrated nitric acid are to be added in small proportions, and the mixture is to be agitated after every new addition; the bottle is then stopped with a cork, which is secured with leather. The mixture is set in a convenient place to avoid the danger of accidents from the bursting of the bottle. In a few hours bubbles rise from the bottom of the vessel, and a stratum of ether is gradually formed on the surface of the liquid. When the action, which generally continues about six days, seems to be over, the cork is pierced with a needle to allow the escape of nitrous gas; and when this gas is gradually dissipated, the cork is withdrawn, and the whole liquid is poured into a funnel; the ether swims on the top, and the remaining liquid, which is heavier, is permitted to pass off, while the ether is retained.

The process contrived by Dr Black is attended with less danger. The nitric acid is first introduced into a bottle, and over this is poured gently a quantity of water, to which the alcohol, which swims on the top, is added. The proportions he employed were four ounces of strong nitric acid, three ounces of water, and six ounces of alcohol; the bottle containing the mixture was placed in water or ice, and the stopper was put in slightly in case of the sudden evolution of elastic fluids; and sometimes he applied a spring to the stopper, so that it returned to its place when the gaseous bodies pass off. By this contrivance, the mixture of the acid and the water on the one hand, and of the water and the alcohol on the other, proceed very gradually; at the end of eight or ten days three ounces of nitric ether are produced.

By whatever process it is obtained, it requires to be farther purified to separate the remaining acid and alcohol; this is done by distilling it from potash; the distillation is to be continued till one-half of the first ether has come over. A farther purification is still necessary, by mixing it with one-fifth of nitrous acid and distilling again; two-thirds of the product being taken and set apart to be rectified from an alkali.

Properties.—Nitric ether is of a yellowish colour; the odour is stronger and less sweet than that of sulphuric ether, and the taste is hot and more disagreeable. It burns with a more brilliant flame, and gives out a denser smoke. When long kept in a close vessel water is formed, holding a small portion of oxalic acid in solution, which falls to the bottom of the vessel. It is more volatile than sulphuric ether. Nitrous acid is formed in nitric ether, when it is kept for some time; and when it is passed through a red hot porcelain tube, carbonic acid, charcoal, nitrous gas, and some other substances are produced. This decomposition indicates the constituent parts of nitric ether, which, according to Thenard, are 48.52 oxygen, 28.45 carbone, 14.49 azote, and 8.54 hydrogen.

3. *Muriatic Ether.*

Two methods have been recommended for the preparation of muriatic ether.

By the first method, a portion of common salt is deprived of its water of crystallization, by keeping it for an hour in a state of fusion; 20 parts of the salt are put into a tubulated retort to which a bent tube is fitted, the extremity of which terminates in a bottle of Woulfe's apparatus, into which ten parts of the strongest alcohol have been introduced; and ten parts of concentrated sulphuric acid are to be added to the salt in the retort, in small portions at a time, while the air from the vessel with the alcohol is permitted to escape. The bottle with the alcohol being kept cool, the retort is placed in a sand bath, and the distillation continued till the muriatic acid passes over and saturates the alcohol. The product is again put into a retort and distilled, till about half the quantity comes over. This portion being washed by an alkaline ley, the ether, which swims on the surface, is separated.

By another process, equal proportions of muriatic acid and alcohol, both as strong as can be procured, are put into a retort, which is nearly of that capacity to contain the mixture. To diminish the violence of the ebullition, some grains of sand are put into the mixture, and a tube passing from the beak of the retort terminates in a large glass jar, furnished with three openings; a tube of safety is secured by a lute into the second opening, and from the third another tube passes into the pneumatic apparatus, to convey the gas that is evolved. With the application of heat, a portion of alcohol, with acid and water, is driven into the receiver; but the ether as it is formed passes off in the state of gas, and must be received in separate vessels.

Properties.—The gas of muriatic ether is colourless, has a sweetish taste, and the odour of sulphuric ether; it becomes liquid at the temperature of 52°, is then colourless, and in smell and taste is similar to the gas. It is extremely volatile, and at 64° assumes the form of elastic fluid; it burns with a greenish coloured flame, and during the combustion muriatic acid, in the state of vapour, is evolved.

The constituent parts of muriatic ether, according to the analysis of Thenard, are, muriatic acid 29.44, carbone 36.61, oxygen 23.31, hydrogen 10.64.

4. *Acetic Ether.*

Acetic ether was first obtained by distilling a mixture of acetic acid and alcohol. Equal quantities of strong acetic acid, such as is obtained from acetate of copper and alcohol, are distilled, and the product of the distillation is twice returned into the retort. After the third distillation the mixture is a compound of acetic acid and ether; potash is added to it to saturate the acid; and being again distilled, the ether passes off in a state of purity.

By another process, 15 parts of acetate of lead, 6 parts of strong sulphuric acid, and 9 parts of alcohol, being mixed together and distilled in a retort till ten parts pass over, and the liquid obtained being washed with a third part of its bulk of lime water, the ether which swims on the surface is separated.

Properties.—Acetic ether is similar in many of its properties to the other kinds; the taste is different, and it has a slight odour of acetic acid. It boils at the temperature of 160°, and burns with a yellowish white flame, and during the combustion acetic acid makes its appearance. Acetic ether is supposed to be a compound of acetic acid and alcohol, in which the properties of the acid are concealed; and hence its constituent parts are carbone, hydrogen, and oxygen.

Ether has also been formed by several other acids, which it would appear have one common property in their action on alcohol; and it has been supposed that all the ethers produced by the different acids are nearly the same, and would exhibit nearly the same properties, were it not that they are contaminated with extraneous matters, derived either from the acids or the alcohol employed in their formation.

Sect. III. *Oils.*

Oils, which are copious productions of nature, constitute a class of bodies which are characterised by combustibility, insolubility in water, and fluidity, and are of very extensive utility in domestic economy and the arts. The peculiar properties of different kinds of oils, form a very natural division into fixed or fat oils, and volatile or essential oils; the first of which, or the fat oils, require a high temperature to raise them to the state of vapour, but the second kind are volatilized with the heat of boiling water, and even at a lower temperature.

1. *Fixed Oils.*

Fixed oils are obtained either from animals or vegetables. Train oil is extracted from the fat or blubber of the whale, as well as from the liver of different animals; and it exists also in the eggs of fowls. Fixed oil is only obtained from the seeds of plants; and from those seeds which have two lobes, of which the seed of lint and the kernels of almonds, furnishing linseed and almond oils, are examples. They are sometimes called expressed oils, because they are obtained from the seeds by subjecting them to strong pressure.

Fixed oils are generally in the state of liquid, but of a viscid consistence; they have a greasy feel, are mild or insipid to the taste; when pure have no smell; are of a greenish or yellowish colour; are insoluble in water, leave a stain upon paper; and their boiling point is not less than 600°.

When exposed to the air, the fixed oils undergo peculiar changes; some of them become thick, opaque, white and granulated, and assume somewhat of the appearance of tallow. Oils subject to this change are called *fat oils*; and this is the case with olive and almond oil. But other oils by exposure to the air dry altogether, and retain their transparency; from this peculiar property they are called *drying oils*, and this property is improved in some of the oils by certain processes, as when linseed oil is boiled with litharge before it is employed by painters. But many of the fixed oils suffer decomposition when they are exposed to the air, and then they are said to become rancid. During this change the colour, smell, and taste are different, and an acid seems to be formed.

With the assistance of heat, phosphorus is dissolved in the fixed oils, and communicates a luminous property. Sulphur also, with the aid of heat, combines with fixed oil; and the solution, which is of a reddish colour, was formerly called *ruby of sulphur;* and when it cools slowly, the sulphur is crystallized into octohedrons. The mixture has a peculiarly fœtid odour, and affords by distillation a great deal of sulphuretted hydrogen gas.

Concentrated sulphuric acid decomposes fixed oil, water is formed, and charcoal is precipitated; nitric acid thickens it; and a mixture of nitrous acid and concentrated sulphuric acid produces inflammation.

2. *Volatile Oils.*

The volatility, fragrance, and acrid taste of volatile oils, afford sufficient characters to distinguish them from fixed oils; they are also called aromatic oils, from their odour, or essential oils, or simply essences.

Volatile oil is found in every part of the plant excepting in the seed from which fixed oil is derived; it is extracted either by simple expression when it is abundant, and is deposited in a fluid state in vesicles, as in the outer rind of the orange and lemon. But in most cases the substances which afford volatile oils are subjected to the process of distillation. After being macerated for some hours in water, they are introduced into a still along with the water; a moderate heat is applied and continued till the fluid boil, when the water rises in vapour, mixed with volatile oil, and is received in proper vessels. The oil collects on the surface of the water, from which it may be easily separated.

Properties.—Volatile oils are distinguished by their fragrance; some of them are thick and viscid, some congeal, and some of them assume a granulated solid consistence, and several of them are susceptible of crystallization. Some of them are nearly colourless, some are blue or green, but yellow or reddish is the prevailing colour; the taste is acrid, hot, and then caustic; the specific gravity is generally less than that of water.

Light deepens the colour, and increases the speci-

Of Alkalies.

fic gravity of volatile oils; they evaporate readily when exposed to heat, and burn with a bright white flame, with a copious evolution of smoke. Exposed to the air, they assume a deeper colour, become viscid, and exhale a strong odour; many of the volatile oils are in this way converted into resins by the absorption of the oxygen of the air; they are slightly soluble in water, and communicate to it their peculiar odour.

Phosphorus is soluble in volatile oils; the solution is luminous in the dark, very fetid, and when heated gives out phosphuretted hydrogen gas. The compound of sulphur and volatile oil, formerly called balsam of sulphur, affords sulphuretted hydrogen gas by means of heat.

Concentrated sulphuric acid produces a brown colour, and increases the viscidity of volatile oils; they are partially decomposed, and charcoal is deposited. Nitrous acid produces an instantaneous deflagration, and converts them into water and carbonic acid, and a bulky mass of charcoal remains behind.

Some of the volatile oils are employed in medicine; many of them are used in perfumery; and they are extensively applied for the solution of those substances which are employed as varnishes.

Tests.—The high price of some of the volatile oils is a strong temptation to adulterate them with other substances. When a volatile oil is contaminated with a fixed oil, it may be detected by an easy test: let a single drop of the suspected oil fall on clean paper, and expose it to a gentle heat; if the oil be pure the whole is evaporated without the slightest trace on the paper; but if adulterated with a fixed oil, a greasy spot remains behind. Oil of turpentine added to other volatile oils, is indicated by the smell; and when they are adulterated with alcohol, a little of the oil mixed with water produces a milky appearance.

Chap. XI. Of Alkalies.

The word alkali is derived from *kali*, the Arabic name of a plant from which that substance is extracted; and the particle *al* is prefixed to express the value or the qualities of the plant. Three substances, potash, soda, and ammonia, exhibit the peculiar characters of the alkalies; and they are distinguished by the following properties—the taste is disagreeably caustic; they convert vegetable blues to green; combine with water in all proportions; have a strong affinity for acids; melt in a moderate heat; and when subjected to a higher temperature rise in the state of vapour.

The alkalies have been divided into *fixed* and *volatile;* the first two, potash and soda, are denominated fixed alkalies, because a very high temperature is requisite to convert them into vapour, and the last, or ammonia, has been called volatile alkali, because it is volatilized by a very moderate heat.

Composition of the alkalies.—Conjectures had been frequently thrown out that the fixed alkalies are not simple substances; but no approach was made to ascertain their composition till the year 1807, when the brilliant discoveries of Sir Humphry Davy fully verified these conjectures, and proved, at least with regard to the fixed alkalies, that they are compounds of oxygen, with a metallic base.

Potash.—If a thin piece of pure potash, prepared according to the process to be detailed in the next section, and slightly moistened, be subjected to the action of galvanism between two disks of platina, it is soon fused, and oxygen gas is separated at the positive end of the battery, while small metallic globules appear at the negative extremity. These globules are the metallic base of potash, which has received the name of *potassium.* But as the potassium obtained by this decomposition is in very small quantity, and the process is expensive, more economical methods have been devised. According to one of these methods potassium is obtained by igniting potash with charcoal. But a more convenient method is to heat a quantity of iron turnings to whiteness in a curved gun barrel, and, to make fused potash come slowly in contact with the turnings; the potassium, as it is evolved, rises in the state of vapour, and is collected at the opposite extremity of the tube, part of which is purposely cooled to condense it. The nature of these processes is sufficiently obvious. The iron and the charcoal at a high temperature deprive the potash of its oxygen, and the metallic base being set free assumes the form of an elastic fluid, which becomes solid when it comes in contact with a cold body.

Properties of potassium.—Potassium is white, like newly cut silver, is hard and brittle, and has a crystalline appearance; at the temperature of 32° becomes soft, and malleable at 50°, and liquid at 100°. It is remarkable for its low specific gravity, which is between 8 and 9, water being stated at 10. Exposed to the air, it tarnishes in a few minutes, and, combining with oxygen, forms a crust of potash. It must therefore be kept under naphtha, the only substance in which it can be preserved free from change. When it is thrown on water it acts with great violence, swims upon the surface, and burns with a beautiful light, which is a mixture of white, red, and violet; the water is decomposed, the hydrogen escapes, and the oxygen, combining with the potassium, forms potash, which is dissolved and produces an alkaline solution.

Potassium combines readily with phosphorus and sulphur; with the first a phosphuret is formed, which burns in the open air, and is converted into phosphate of potash. In its combination with sulphur, light and heat are given out; and when the sulphuret is exposed to the air, it is soon changed into sulphate of potash.

The properties and combinations now enumerated afford satisfactory evidence of the compound nature of potash, and the proportion of the constituent parts are stated at 86 of potassium and 14 of oxygen.

Soda.—The decomposition of soda was effected by the same chemical philosopher about the same time, and in a similar manner; and to the metallic base the name of *sodium* has been applied.

Properties of Sodium.—Sodium, in many of its characters, is analogous to potassium; it is white like silver, with a high degree of lustre, melts at the temperature of 200°, and requires a red heat to raise it into vapour; the specific gravity is between 9 and

10; when it is exposed to the air it is soon tarnished, and covered with a crust of soda; it burns with great brilliancy when heated in oxygen gas, and when thrown into water it effervesces strongly, but is not inflamed, swims on the surface, and is gradually diminished, while the water becomes alkaline, with a solution of soda. In general the action of sodium is less powerful than that of potassium on other substances. It combines with sulphur and with phosphorus, and the compounds exhibit analogous properties, with similar combinations of potassium.

The constituent parts of soda are stated at 78 of sodium and 22 of oxygen; and it appears that the sodium combines with oxygen in two proportions and forms two oxides.

Ammonia.—Two of the constituent parts of ammonia, hydrogen and azote, have been long known; but after the discovery of the composition of the fixed alkalies, it was conjectured that ammonia, or the volatile alkali, possessing many analogous properties, might be constituted in a similar manner; and this conjecture receives some degree of confirmation from a galvanic experiment, in which mercury seems to enter into combination with the metallic base of ammonia, and to form an amalgam. To this base the name of ammonia is given. If about 50 grains of mercury be placed in the cavity of a piece of sal ammoniac slightly moistened, and if the sal ammoniac be connected, by means of a plate of platina, with the positive extremity of the galvanic battery, and a wire of platina, proceeding from the negative end, be brought in contact with the mercury, a strong effervescence is produced with the evolution of heat; the globule of mercury is enlarged in bulk, and assumes the appearance of an amalgam of zinc. At the temperature of 70° or 80°, it is of a soft consistency, and when reduced to the temperature of 32° it exhibits somewhat of a crystalline appearance. In the open air it is soon covered with a white crust of carbonate of ammonia; and when confined in a given quantity of air, the air is enlarged in bulk, ammoniacal gas and a portion of oxygen gas are given out, and the mercury is revived; but experiments are still wanting fully to establish the analogy of composition between ammonia and the fixed alkalies.

Sect. I. *Potash and its Combinations.*

Potash, formerly called vegetable fixed alkali, because it is obtained from vegetables, is known in commerce under different names. It is called *potash*, because it is prepared in iron pots, and *pearl-ash* from its appearance after farther purification, and it is well known under the name of *salt of tartar*. But in these states it is far from being pure. The potash of commerce is generally obtained from wood ashes, and the greater proportion of it which is employed in the arts of this country is imported from Russia and North America, where wood is abundant.

Purification.—The potash of commerce, or the salt of tartar of the shops, is generally mixed with extraneous substances, or is combined with carbonic acid, from all which it is necessary to be freed for many purposes. It may be purified by the following process: Potash being mixed with double its weight of quicklime, and 8 or 10 times its weight of pure water being added, the mixture is boiled for two or three hours in an iron vessel, after which it remains for 48 hours in a close vessel, and is occasionally agitated; it is afterwards filtered and boiled in a silver vessel, with a strong heat, till it assume the consistence of honey. Add a quantity of alcohol, equal in weight to about one third of the alkali employed, boil it for a few minutes, and then pour it into a bottle, and after it is cool it separates into three different strata; at the bottom are deposited solid matters; in the middle an aqueous solution of carbonate of potash, and the uppermost is a reddish brown liquid, which is a solution of pure potash in alcohol; the latter is carefully decanted off, and evaporated rapidly in a basin of silver, or of tinned copper, till a dry charry crust appear on the surface. Remove this crust, and pour the solution into porcelain vessels, and when it cools it becomes solid; it is then broken in pieces, and put into close vessels. This process is greatly improved by distilling the solution in alcohol in a silver still; the alcohol is driven off, and the pure potash remains behind.

Pure potash may be prepared by boiling together equal parts of purified salt of tartar, and white marble, or oyster-shells calcined, with a sufficient quantity of water, in a polished iron kettle. Strain the ley through clean linen, and reduce it by boiling till it contain about half its weight of caustic alkali. It is again passed through a linen cloth, and afterwards set by in a glass bottle, and when it becomes clear it is poured off from the sediment into another bottle, in which it is preserved for use in the liquid form.

Properties.—Potash is of a white colour, brittle, and of a crystalline texture; the taste is very acrid, and it is so corrosive that it destroys the texture of animal and vegetable substances. The specific gravity is 1.7.

When it is heated it melts, and when the temperature is raised to a red heat it is sublimed in the form of a white acrid vapour. Water dissolves double its weight of potash; the solution is colourless and transparent, and nearly of the consistency of oil. Sulphur unites with potash, and forms a sulphuret; and it readily combines with the acids, some of the compounds of which are of great importance. Potash is very soluble in alcohol, and the solution is of a red colour; it readily unites with the fat oils, and forms with them soft soap; and it combines sparingly with the volatile oils, and the compound is also of a soapy nature.

Sulphuret of Potash.—If one part of potash and three of sulphur be triturated together in a glass mortar, the mixture becomes hot, and acquires a greenish tinge, gives out a fœtid smell of garlic, attracts moisture from the air, and is almost entirely soluble in water. But if two parts of potash and one of sulphur be mixed together, and fused in a crucible, sulphuret of potash is obtained in the dry state. This substance was formerly called liver of sulphur, from its resemblance to the liver of animals. When the the fusion is completed, the mass is poured out on a marble slab, and covered up from the air till it cool, when it is broken into small pieces.

Properties.—The sulphuret of potash is of a shining brown colour, has a smooth and somewhat vitreous fracture, an acrid bitter taste, and when it touches the skin leaves a brown spot; it converts vegetable blue colours to green. With a strong heat in a close vessel the sulphur is sublimed, and the potash remains in a state of purity at the bottom of the vessel.

Hydrosulphuret of Potash.—When sulphuret of potash is exposed to the air it absorbs moisture, acquires a green colour, and exhales the fœtid odour of sulphuretted hydrogen gas; the water which has been absorbed is decomposed, and its hydrogen combining with a portion of the sulphur, forms sulphuretted hydrogen gas. This hydrosulphuret is prepared either by saturating potash, or it may be formed by dissolving sulphuret of potash in water, and evaporating the solution, when the hydrosulphuret is obtained in crystals, which are in the form of four-sided prisms. It has no smell, but the taste is alkaline, and very bitter; when exposed to the air it attracts moisture, and gives out a fœtid odour; it is soluble in water and in alcohol, and during the solution the temperature of the liquid is greatly reduced. Acids produce a violent effervescence, and expel the sulphuretted hydrogen, without the deposition of sulphur.

Hydroguretted Sulphuret of Potash.—If liquid hydrosulphuret of potash be poured upon sulphur, the latter is dissolved without the assistance of heat, and the liquid assumes a darker colour, and is converted into the hydroguretted sulphuret. The same compound may be prepared by boiling together a mixture of pure potash and sulphur in water; the liquid is of a deep red colour, inclining to brown; the taste is acrid, and somewhat cooling; sometimes it is without smell, but after being kept gives out the odour of sulphuretted hydrogen gas. This compound has a very powerful action on many substances, and particularly on metals; it readily absorbs oxygen when exposed to the air, and when kept in close vessels it deposits sulphur, the liquid becomes transparent, and the smell is dissipated.

Sulphate of potash.—This salt is a compound of sulphuric acid and potash. It has been distinguished by various names, as *sal de duobus*, *sal polychrestus*, or salt of many virtues; *arcanum duplicatum*, or double secret; and more lately *vitriolated tartar*, till it was denominated in the new nomenclature *sulphate of potash.*

According to the principles of the present chemical nomenclature, the saline compounds of acids with alkaline, earthy, or metallic bases, are distinguished by a name which is expressive of their composition. Two words are employed, the first of which, derived from the acid, is the generic term, and the second, taken from the base, refers to the species. Thus sulphate of potash indicates the compound of sulphuric acid and potash, and in this case the generic term ends in *ate*; but when acids, with a smaller proportion of oxygen, combine with bases, as in the case of sulphurous acid, the generic name terminates in *ite*, as sulphite.

In many cases acids and their bases unite together in different proportions. Sometimes the acid is in excess, and sometimes the base; in the present example, if sulphuric acid be in smaller proportion than it exists in sulphate of potash, the word *sub*, expressive of this under proportion, is prefixed, as *sub-sulphate* of potash. But if the acid be in larger proportion, the word *super* is prefixed, as *super-sulphate* of potash.

Sulphate of potash is prepared either by the direct combination of sulphuric acid and potash, or by the decomposition of other salts which have potash for their base, by means of sulphuric acid, which, from its stronger affinity for the potash, combines with it, and forms a new compound. When the solution is purified and evaporated the salt is obtained in crystals, but it forms regular crystals only by slow spontaneous evaporation.

Properties.—This salt crystallizes in short six-sided prisms, terminated by six-sided pyramids; the taste is disagreeably bitter; the specific gravity is from 2.4 to 2.6. One part of the salt is soluble in 16 times its weight of water at 60°, and requires only 5 times its weight of boiling water. It remains unchanged in the air, decrepitates when placed on burning coals, and at a red heat melts, and is converted into a kind of enamel. Exposed to a red heat, along with hydrogen gas or carbone, it suffers decomposition, and becomes a sulphuret of potash; the hydrogen and the carbone unite with the oxygen of the acid, and leave the sulphur in combination with the potash. Sulphuric acid, with the aid of heat, forms another compound with this salt, in which the acid is in excess.

The constituent parts of sulphate of potash, according to the analysis of different chemists, are from 43 to 47 of acid, and from 53 to 57 of base. It is supposed to be destitute of water of crystallization.

This salt was at one time much employed in medicine, and extraordinary virtues were ascribed to it.

Super-sulphate of potash.—This saline compound is prepared by heating together in a retort three parts of sulphate of potash with one part of its weight of concentrated sulphuric acid; it crystallizes in the form of long flexible slender needles; the taste is hot and acrid; it reddens vegetable blues, indicating an excess of acid; becomes slightly opaque when exposed to the air; requires two parts of cold water, and less than its own weight of boiling water for its solution; it melts readily by the application of heat, and presents the appearance of a thick oil, and, on cooling, becomes a white opaque mass. When subjected to strong heat, the excess of acid is expelled, and it is converted into sulphate of potash.

The proportion of acid in this salt is double of what it is in the sulphate of potash.

Sulphite of potash.—This salt is a compound of sulphurous acid and potash, and was long known under the name of the sulphurous salt of Stahl; it is formed by passing a current of sulphurous acid gas into a saturated solution of carbonate of potash, till the effervescence ceases; the liquid becomes transparent and hot; and, on cooling, white transparent crystals, in the shape of small needles diverging from a centre, or in romboidal plates, are formed; the taste is acrid and sulphurous; it is very soluble in water; exposed to the air, the solution is soon covered with a thick pellicle, which falls to the bottom, and is soon succeeded by another. This is the sulphate of potash, formed by the sulphurous acid combining with the oxygen of the atmosphere. Sulphite of potash, subjected to sudden heat, decrepitates, and is deprived of its water of crystallization and part of its acid; sulphur is separated, and what remains is sulphate of potash.

Nitrate of potash.—Nitrate of potash, which is a compound of nitric acid and potash, is a familiar substance in commerce and domestic economy, under the names of salt-petre and nitre. It is one of the most important saline compounds, not only on account of the attention which it has excited in the investigation of its nature and composition, but also on account of its numerous and valuable applications to the arts of life.

Nitrate of potash exists ready formed in some plants, as in tobacco and borage, and it has been observed crystallized in the form of needles in their dried stalks. It exists in great abundance on the surface of the earth in different parts of the world, especially in India, Egypt, and South America. It is produced artificially in Germany and France, by means of what are called *nitre-beds*, which are formed by collecting together the refuse of animal and vegetable matters in a state of putrefaction, and mixing them with earthy matters, but chiefly with calcareous earth, or with the rubbish from old buildings, or portions of the soil in which lime abounds. Moisture, which is supplied by the occasional addition of water to the mixture, a moderate temperature, and protection from the rain, which would wash away the salt as it is formed, are the only requisites which favour the production of nitre.

The nature of this process may be understood by considering the constituent parts of nitre. The base of nitric acid, azote, is separated from animal matters during the putrefactive process, in the form of azotic gas, which, at the moment of its evolution, unites with the oxygen of the air, and forms nitric acid, and the potash is furnished by the soil or the vegetable matters.

After a certain time, which is longer or shorter according to the nature of the ingredients and other circumstances, the nitre which is formed being mixed with water and evaporated, a brown coloured salt, which is called crude nitre, is obtained; it is a mixture of several salts, from which the pure nitre is separated by repeated solutions and crystallizations. After sufficient purification, it is obtained in the form of six-sided prisms terminated by six-sided pyramids.

Properties.—Nitrate of potash is peculiarly distinguished by a cool, sharp, and bitterish taste; is very brittle, and when large crystals are reduced to powder it is somewhat moist; but when it is in the form of a white opaque mass, it yields a dry powder. The specific gravity is 1.93; it is not changed by exposure to the air; water at 60° dissolves a seventh part of its weight, and great cold is produced during the solution; but boiling water dissolves twice its weight of the salt.

Nitrate of potash, when heated, melts and assumes an oily consistence; when cool, it congeals into an opaque mass called mineral crystal. This fusion produces no change, but when the temperature is increased, oxygen gas is given out, and afterwards azotic gas, while the potash remains behind.

Nitrate of potash is decomposed by means of charcoal; a violent action is produced by exposing a mixture of charcoal and nitre to a red heat; the carbone unites with the oxygen of the acid, and forms carbonic acid, azotic gas is disengaged, and the alkali remains behind, which was formerly called *nitre fixed by charcoal*, or an *extemporaneous alkali of nitre*. When this process was conducted in close vessels, a small portion of water appeared, and to this product the name of *clyssus* was given by the alchemists, who ascribed to it very wonderful properties in the preparation of the philosopher's stone. When phosphorus and nitre are heated in the same way, a violent deflagration takes place; but an experiment of this kind must be performed with great caution, and in very small quantities. Sulphur and nitre, when exposed to a high temperature, also exhibit a violent action. The sulphur combines with the oxygen of the nitric acid, forming sulphuric acid, which enters into combination with potash.

Fulminating powder is prepared with three parts of nitre, two parts of potash and one of sulphur, previously well dried and mixed together, by trituration in a mortar. This compound, when heated, produces a violent explosion.

Gunpowder is a compound of 76 parts of nitre, 15 of charcoal, and 9 of sulphur. The different ingredients which, it may be observed, are employed in different proportions by different manufacturers, are separately reduced to fine powder, and, after being well mixed, are formed into a thick paste with a little water; when the paste has dried a little, it is forced through a sieve, and reduced to grains of the requisite size; it is then dried in the air or the sun, put into barrels, which are turned round by means of machinery, and thus, by the friction of the grains upon each other, and against the sides of the barrel, they become smooth and polished. This is called *glazing* the powder. The terrible effects of the explosion of gunpowder, are accounted for by the changes which are instantaneously produced on the different ingredients of which it is composed. The sulphur and the charcoal burn with great rapidity by the addition of the nitre with which they are intimately mixed; and during this combustion, carbonic acid gas, azotic gas, sulphurous acid gas, and sulphuretted hydrogen gas, with a portion of water and ammonia, are formed; and it is obvious that its irresistible effects are owing to the sudden evolution and expansive force of these elastic fluids. Carbonate of potash, sulphate and sulphuret of potash, with some charcoal, are the substances which remain after the deflagration.

Black and white flux.—A mixture of equal parts of nitre and tartar, detonated in a red hot crucible, afford the compound called *white flux*, which is a mixture of pure potash with the carbonate, and is much employed in metallurgy. But if one part of nitre and two of tartar are treated in the same way, the product obtained is a mixture of potash and charcoal; from its black colour it is known under the name of *black flux*, and is applied to similar purposes.

Powder of fusion, which is so called from its powerful effects on metallic substances, is composed of three parts of nitre, one of sulphur, and one of sawdust. The different ingredients should be well dried, and thoroughly mixed together.

The constituent parts of nitre are 43 of acid, 40 of potash, and 17 of water.

Exper. 1.—Melt a quantity of nitre in a crucible, and when it is brought to a red heat, project into it a little powdered and well dried charcoal; at every addition of the charcoal a brilliant combustion takes place, in consequence of the rapid decomposition of the salt.

Exper. 2.—A similar effect is produced with phosphorus and nitre; but the danger of the experiment may be avoided by folding up in a paper a few grains of nitre, with a small quantity of phosphorus, both well dried, and striking the mixture smartly with a hammer on an anvil, or other solid body, a violent detonation takes place.

Exper. 3.—Take three parts of nitre, and one of sulphur, and project them in small quantities into a red hot crucible; a detonation takes place, and the sulphur is converted into sulphuric acid.

Exper. 4.—By combining the ingredients of gunpowder by two and two, as the nitre and the charcoal, and the nitre and the sulphur, and the charcoal and the sulphur, and setting fire to these compounds, and then mixing all the three ingredients in the usual proportions, their effects maybe distinctly observed.

Exper. 5.—Place a few grains of the compound called fulminating powder, on a plate of iron or copper, and hold the plate over the fire, the powder first assumes a dark colour, and then melts, and when the whole is in fusion, a violent explosion takes place; the heat should be applied slowly and gradually till the mixture is completely fluid, and then by bringing it nearer to the heat, the full effect of the explosion is obtained. This combustion and explosion are also owing to the instaneous evolution of elastic fluids, similar to what takes place at the explosion of gunpowder.

Exper. 6.—An amusing experiment is made with the powder of fusion. If a walnut shell be filled with this powder, and a thin plate of copper, rolled up, be inserted in the middle, and the powder be set fire to, it burns with great rapidity, and the metal is reduced to the state of sulphuret, without injury to the shell.

Nitrite of potash.—This salt is not formed by direct combination of nitrous acid with the alkali; but after nitre has been subjected for some time to a strong heat, a salt remains which is deliquescent and acrid, changes vegetable blues to green, and by the action of sulphuric, nitric, muriatic, and other strong acids, gives out red vapours, which are the fumes of nitrous acid.

Muriate of potash.—This salt, formerly called febrifuge salt of Sylvius, digestive salt, and regenerated sea salt, may be prepared by direct combination of muriatic acid and potash; the saturated solution is evaporated till a pellicle appears, when it is set by to crystallize. The crystals are in the form of cubes, or right angled parallelopipeds; the taste is bitter, and the specific gravity is 1.8. It deliquesces in moist air; cold water dissolves one-third of its weight; it is more soluble in boiling water; but regular crystals can only be obtained by slow spontaneous evaporation.

Exposed to heat it decrepitates, and is deprived of its water of crystallization; when the temperature is raised it sublimes unchanged in the form of white vapour.

It is decomposed by means of sulphuric and nitric acids; by the action of the first, muriatic acid is disengaged, and by means of nitric acid, oxymuriatic acid or chlorine, is separated. With one part of nitric acid and two parts of muriate of potash, a compound of the two acids, or nitromuriatic acid is obtained.

The constituent parts of this salt are 36 parts of acid and 64 parts of potash.

But according to the views of Sir Humphry Davy, relative to the constitution of muriatic acid, muriate of potash is a compound of chlorine and potassium, the metallic base of potash.

Hyper-oxymuriate, or chlorate of potash.—This saline compound, which possesses very remarkable properties, was first prepared by Dr Higgins, by passing a current of oxymuriatic acid gas into a solution of potash. He gave it the name of nitre, and observed that it detonated on red hot coals; but it was more accurately examined by the sagacious Berthollet.

Preparation.—If a quantity of potash, with six times its weight of water, be put into a bottle of Woulfe's apparatus, and a current of oxymuriatic acid gas be passed through it till the potash is saturated, crystals in the form of fine white scales fall to the bottom. These crystals being removed from the solution, are purified by dissolving them in boiling water; and the solution being filtered and allowed to cool, crystals are again deposited.

Properties.—The crystals of this salt are usually in the form of square plates or parallelopipeds, of a shining silvery white colour; they are transparent and brittle, and the taste is cool, pungent, and disagreeable. This salt becomes yellow by long exposure to the air, but remains otherwise unchanged; it is soluble in 20 parts of cold water, and boiling water absorbs one-third of its weight; it fuses quickly when exposed to heat, and when the temperature is increased it gives out a large proportion of the purest oxygen gas.

This salt exhibits very remarkable effects with combustible substances. Even when it is smartly rubbed, without any addition, it gives out sparks or luminous traces; but rubbed with charcoal, sulphur, phosphorus, various vegetable, and some metallic substances, it produces detonations. When sulphuric acid is poured on the salt, a violent action, with the evolution of white flame, takes place, and sometimes the vessel in which the experiment is made is shattered to pieces by the explosion. Nitric acid poured upon it occasions a crackling noise and effervescence, but without flame or explosion. Muriatic acid disengages the acid of the salt.

The constituent parts of this salt are 58 of acid, 39 of potash, and nearly 3 of water. According to the former views, the acid is a compound of muriatic acid, with a larger proportion of oxygen than what exists in oxymuriatic acid, and therefore it was called hyper-oxymuriatic acid; but, agreeable to the theory of Sir Humphry Davy, this acid is a compound of chlorine and oxygen, which has been already described in the chapter on acids, under the name of chloric acid. This salt was, at one time, employed in bleaching, but a similar compound, with lime, which is much cheaper, is now used as a substitute. Its remarkable power of detonation suggested its use in place of nitre in the composition of gunpowder; and an attempt was made in 1788, at Essone in France, to prepare it in the large way; but the spontaneous explosion of the mixture, which was attended with the fatal accident of the death of a lady and gentleman who witnessed the experiment, prevented its effects from being fairly tried.

Exper. 1.—Reduce two or three grains of the salt to a fine powder, and mix it well on paper with an equal quantity of finely powdered charcoal, and then rub the mixture strongly in a mortar, the charcoal will be inflamed, but with a very slight explosion; if a grain of sulphur be added to the mixture a more rapid flash, and a louder explosion are produced. For the success of this experiment, the materials, particularly the charcoal, should be perfectly dry, and the mortar should be warm, and in performing the experiment the hand ought to be protected with a handkerchief or glove. The carbone of the charcoal combines with the oxygen of the acid, and forms carbonic acid, which unites with the potash; and if sulphur be employed, sulphuric acid is formed, and the chlorine is set at liberty. The rapid decomposition is promoted by the friction.

Exper. 2.—Take two grains of the salt and about two-thirds of the same quantity of sulphur, reduce them separately to fine powder, and when they are well mixed together press the pestle of the mortar forcibly upon the mixture; a loud report, with a rapid flash of light, will be produced; or if the different parts of the mixture be successively subjected to pressure, the repeated explosions are like the smart cracks of a whip. This experiment may be varied by wrapping up the mixture of salt and sulphur in a piece of tinfoil, and striking it smartly with a hammer on an anvil. Similar changes take place in this experiment.

Exper. 3.—Reduce one grain of the salt to powder, and bring it together to one place at the bottom of the mortar, take a single grain of phosphorus, place it on the powdered salt, and rub it strongly with the pestle; a loud explosion instantly takes place, while a bright flash of fire is emitted. This experiment may be also varied by wrapping up the salt and phosphorus in tinfoil, and subjecting it to percussion; but in whatever way the experiment is made, every precaution to prevent the materials from being thrown about ought to be observed. The sudden changes are accounted for in the same way as in the preceding experiments.

Exper. 4.—Reduce five grains of the salt to powder, and mix it with six or seven grains of loaf-sugar; if a drop of concentrated sulphuric acid be added to the mixture it will be instantly inflamed, but without explosion.

Exper. 5.—Put six drachms, by measure, of nitrous acid into a tall ale glass, pour gently over it, down the sides of the glass, two or three drachms of water, that the two fluids may be kept separate; then drop in a bit of phosphorus not larger than the size of half a pea. If eight or ten grains of the chlorate of potash be added the phosphorus takes fire, burns vividly at the bottom of the vessel, and throws up brilliant streams of fire to the surface of the fluid. Caution ought also to be observed in this experiment.

Exper. 5.—If two or three drachms of spirit of wine be put into a tea-cup, and eight or ten grains of chlorate of potash be added, and if sulphuric acid, to the amount of two or three drachms, be poured on the mixture, small fire-balls of a blue colour dart from the fluid, and soon after the whole bursts into flame.

Phosphate of potash.—Phosphoric acid combines with potash in three proportions. In the first, or phosphate, the acid and alkali are saturated. It is formed by the direct combination of phosphoric acid and potash. Carbonate of potash is added to warm phosphoric acid till the solution produce no change on vegetable blue colours; by evaporating and cooling, transparent crystals in the form of four-sided prisms, terminated by four-sided pyramids, are obtained; the taste is cooling, the crystals undergo no change by exposure to the air, are very soluble in water, and become liquid when subjected to a red heat.

Super-phosphate of potash.—This salt may be prepared by dissolving the former in phosphoric acid to saturation; it is in the form of jelly, and scarcely crystallizes, is very deliquescent, and very soluble in water when subjected to strong heat.

Sub-phosphate of potash.—If pure potash be fused with the neutral phosphate, the sub-phosphate of potash is obtained, in which the base is in excess. A similar compound may be prepared by boiling the super-phosphate of potash in a solution of potash; a white powder, which is the sub-phosphate, falls to the bottom. It is nearly tasteless, only soluble in hot water, and is very fusible by heat.

Carbonate of potash.—This salt is a compound of carbonic acid and potash, and has been known under various names descriptive of its properties or of the substances from which it is extracted. It is obtained from vegetable matters by burning and washing out the salt from the ashes and evaporating the solution. But the potash thus prepared, besides being contaminated with foreign ingredients, is not fully saturated with carbonic acid. This compound is obtained by passing a current of carbonic acid through a solution of pure potash; the carbonate crystallizes at the surface of the liquid, and the crystals, after being dried on paper, must be kept in well closed bottles.

The carbonate of potash crystallizes in four-sided prisms, with two-sided summits; the taste is sweet and alkaline, and it changes vegetable blues to green; it is soluble in four times its weight of water; boiling water dissolves a larger proportion; and carbonic acid gas escapes during its solution in the latter, so that it is partially decomposed. It is not changed by exposure to the air; when heated, part of the carbonic acid is driven off; all other acids drive off the carbonic acid.

The constituent parts of carbonate of potash are 43 of carbonic acid, 41 of potash, and 16 of water.

Compounds of Potash.

Sub-carbonate of Potash.—The potash of commerce, or even when it is purified and known by the name of salt of tartar in the shops, is never fully saturated with carbonic acid ; and indeed it is proved by experiment, that it contains exactly one half of the carbonic acid which exists in the carbonate. It is also different in its other properties ; it is more acrid and corrosive, the taste is more strongly alkaline, and it is very deliquescent.

The potash of commerce is always contaminated with a portion of sulphate and muriate of potash, besides some insoluble matters.

Test of its purity.—It is of much importance to the manufacturer to be able to ascertain by a simple test the quantity of pure potash in the different kinds that are brought to market. The quantity of the earth of alum which the potash to be examined can precipitate, is proposed as one test ; that is, by adding the potash to a solution of alum in water, and observing the quantity of precipitate obtained from a determinate proportion of potash. Another test is, to saturate a portion of the alkali to be tried with nitric acid of known density. By repeated solution and crystallization, the other salts may be separated.

Arseniate of Potash,—Which is a compound of arsenic acid and potash, seems not to crystallize, is deliquescent, gives a green colour to syrup of violets, but produces no change on tincture of turnsole. Strongly heated, it melts into a white glass, and part of the potash combining with the silica and alumina of the crucible, it passes to the state of superarseniate ; when subjected to a red heat, in close vessels, the arsenic is sublimed, and it is decomposed by sulphuric acid. Salts, with a base of lime or magnesia are decomposed, and arseniates of lime or magnesia are formed in the solution.

Superarseniate of Potash.—If arsenic acid be added to the arseniate of potash till it no longer affect the colour of violets, but reddens the tincture of turnsole, the solution, when evaporated, yields transparent four-sided crystals, terminated by four-sided summits. It may be prepared by decomposing nitrate of potash, by means of white oxide of arsenic in equal proportions. It was called the *arsenical neutral salt of Macquer* ; and as it crystallizes, reddens vegetable blues, and is unfit to decompose salts with a base of lime or magnesia, its characters are sufficiently distinct from the former.

Acetate of Potash.—This saline compound of acetic acid and potash was known by various names, as *regenerated tartar*, *secret foliated earth of tartar*, *essential salt of wine*, &c. It may be formed by saturating carbonate of potash with distilled vinegar, and by slow evaporation with a very moderate heat, otherwise the acid is apt to be decomposed.

This salt has a slightly alkaline and pungent taste, is deliquescent in the air, is very soluble in water, and if the solution be diluted a spontaneous decomposition takes place in close vessels, with the deposition of mucous flakes. When heated, it melts and froths up, is decomposed and charred ; and when distilled it also suffers decomposition, and potash mixed with charcoal remains in the retort. The first product of distillation is an acid liquid in which, according to the experiments of Proust, ammonia and prussic acid are found, and, according to the same chemist, carbonate and prussiate of potash remain in the retort.

Oxalate of Potash.—This salt is prepared by saturating oxalic acid with potash ; but in this state the salt forms only a gelatinous mass. When there is a slight excess of acid or base, crystals in the form of six-sided prisms may be obtained. When two parts of carbonate of potash, and one part of acid are employed, the crystals redden the syrup of violets, and the tincture of litmus.

Superoxalate of Potash.—This saline compound, with an excess of acid, may be prepared by the gradual addition of potash to a saturated solution of oxalic acid, till a precipitation commences. The crystals are in the form of opaque parallelopipeds ; the taste is acid, pungent, and bitterish ; and they are not very soluble in cold water but dissolve in about ten times their weight of boiling water. They remain unchanged in the air, but are decomposed by heat. This salt contains double the proportion of acid which exists in the neutral compound.

In the plants called *oxalis acetosella*, or wood-sorrel, *rumex acetosa*, or sheeps-sorrel, this salt exists ready formed ; and because it is extracted from these plants, which are common in this country, it is distinguished by the name of *salt of sorrel.* It is employed under the name of *essential salt of lemons*, to remove ink stains and iron moulds, and is sold in the shops for that purpose.

Quadroxalate of Potash.—Another compound of oxalic acid and potash has been discovered, in which the proportion of acid is four times that of the oxalate. It is prepared by adding nitric or muriatic acid to the superoxalate, by whose action the latter is deprived of one half of its base. By evaporation and crystallization, the salt may be obtained in a state of greater purity.

Tartrate of Potash.—The compound of tartaric acid and potash, formerly denominated *soluble tartar*, is prepared by adding the *cream of tartar* of the shops to a hot solution of carbonate of potash till effervescence ceases ; and the solution being boiled for a little, filtered, and evaporated, till a pellicle appears on the surface ; after slow cooling, crystals in the form of long rectangular prisms, with two-sided summits, are deposited. This salt has a bitterish taste ; is deliquescent in the air ; four parts of cold water, but a smaller proportion of boiling water, are required for its solution ; it swells up and blackens when heated ; and when distilled yields an acid liquid, with great abundance of gas, and leaves behind the alkali mixed with charcoal. The stronger acids deprive it of part of the potash, and reduce it to the state of supertartrate ; and the same salt is formed by the addition of tartaric acid.

Supertartrate of Potash.—In this compound, as the name indicates, the acid is in excess. If the crust called tartar, found on the sides and bottom of casks in which wine has been kept, be dissolved in boiling water, filtered, and evaporated, crystals of the pure salt are copiously deposited as the liquid cools, and are well known under the name of *cream of tartar.*

The crystals are chiefly in the form of six-sided prisms ; the taste is acid, and somewhat unpleasant ;

and 60 parts of cold and 30 of boiling water are required for the solution of this salt. It is not changed in the air. By the action of heat, it froths up and blackens; and by distillation, an impure acetic acid is expelled, with a copious evolution of carbonic acid gas. The constituent parts are stated at 57 of acid, 33 of potash, and 7 of water.

Citrate of Potash.—This salt is prepared by dissolving about 61 parts of carbonate of potash in 36 parts of citric acid. The salt obtained by evaporation and cooling is little disposed to crystallize, is very soluble in water, and deliquescent in the air. It is composed of 55.55 acid, and 44.45 of potash.

Camphorate of potash.—Camphoric acid saturated with carbonate of potash till the effervescence ceases, affords by evaporation, with a moderate heat and cooling, crystals which are white and transparent, and in the form of regular hexagons. The taste of camphorate of potash is bitterish and slightly aromatic; in dry air it is not changed, but loses its transparency in moist air. Four parts of boiling water are sufficient for its solution, but it requires 100 parts of cold water.

Under the blow-pipe it gives out a blue flame, the acid is dissipated, and the base remains behind; when strongly heated the acid is sublimed, and it gives out a thick, slightly aromatic smoke. By the addition of the stronger acids to a concentrated solution of this salt, the camphoric acid crystallizes when the solution cools. Camphorate of potash is soluble in alcohol, and burns with a blue flame. It is decomposed by all salts having lime for their base.

Sect. II. *Soda and its Combinations.*

Soda, from the supposition that it existed only in the mineral kingdom, was formerly denominated *fossil or mineral alkali*, and it is the detersive substance mentioned in Scripture, under the name of *nitre*. It is a very abundant production of the soil in some parts of the earth, as in Egypt, where it is called *natron*, and it is sometimes found on the walls of caves or places under ground, or on old edifices. But the soda of commerce is extracted from different plants which grow near the sea shore,—as the *salsola soda*, from which the Spanish barilla ashes are obtained, and in this country, *kelp*, in which the soda is in a very impure state, is prepared by burning different species of *fuci* or sea-weeds. Common salt, so abundant in the waters of the ocean, and forming large solid masses in the earth in some parts of the globe, is a compound of soda and muriatic acid.

Soda and potash approach very nearly to each other in many of their properties, and indeed they were long confounded together. Oxalic acid has been proposed as a test to distinguish the two alkalies; a few grains of the solid acid being added to a solution of potash, forms with it a very soluble salt; but the compound with soda is nearly insoluble.

Soda may be purified by the same process which has been already described for the preparation of pure potash. When in a state of purity, it is usually in the form of solid plates of a greyish white colour; the taste is similar to that of potash, and it has the same caustic and corrosive property; it changes vegetable blues to green, and the specific gravity is 1.3. By slow evaporation from a solution in alcohol, it crystallizes in the form of prisms, and the crystals when exposed to the air soon effloresce and fall to powder. When exposed to heat, it liquifies and becomes of an oily consistence; with a red heat, it is raised to the state of vapour, which is extremely acrid and corrosive. When exposed to the air, it first becomes moist and soft by the absorption of water and carbonic acid, and when the air is dry, it effloresces and falls into powder; it has a strong affinity for water; when the dry alkali is moistened with water, it is absorbed, and becomes solid with the extrication of heat.

Soda is applied to similar purposes with potash; in some kinds of manufactures it is preferred to the latter, because it is less acrid and corrosive, and is therefore less apt to injure the texture of animal and vegetable substances which are subjected to its action.

Sulphuret of soda.—Sulphuret of soda is prepared according to the same process which is followed in the preparation of sulphuret of potash; and in most of its properties, it is analogous to the latter compound.

Hydrosulphuret of soda.—If a current of sulphuretted hydrogen gas be passed into a solution of soda, the gas is absorbed and condensed till the alkali be saturated. The compound thus formed is hydrosulphuret of soda, and it affords a crystallized salt in the form of four sided prisms, terminated by quadrangular pyramids. The crystals are transparent and colourless, without smell, but with a very bitter taste, very soluble in water, deliquescent in the air, and assuming a green colour, and decomposed by the action of acids which expel sulphuretted hydrogen gas.

Hydroguretted sulphuret of soda.—When dry sulphuret of soda is dissolved in water, the water is decomposed, part of the sulphur combines with the hydrogen of the water, and forms sulphuretted hydrogen gas, which combines with the sulphuret, and forms hydroguretted sulphuret of soda; the liquid becomes of a deep red colour; after being kept for some time, it acquires the smell of sulphuretted hydrogen gas; the taste is acrid, bitter, and cooling, and it communicates a green stain to the skin. This liquid has a very powerful action on metallic substances.

Sulphate of soda.—This salt is a compound of sulphuric acid and soda, which is well known under the name of Glauber salt. It may be prepared by the direct combination of the acid and alkali; but it is usually obtained by the decomposition of sea salt, by means of sulphuric acid in the manufacture of sal ammoniac. The solution being filtered, purified, and slowly evaporated, transparent crystals, in the form of six sided prisms, terminated by two sided summits, are obtained. This salt has a cool, bitter, and nauseous taste, effloresces in dry air, is very soluble in cold water, and requires for its solution only about three fifths of its weight of boiling water.

When it is exposed to heat, it first undergoes what is called the *watery fusion*, which is the separation of its water of crystallization, and when this is expelled a dry powder remains behind. When subjected to a long continued red heat, it melts again, and this is called the *igneous fusion*; but in these processes no change has been effected, for when it is dissolved in water and crystallized it returns to its former condition.

Sulphate of soda is decomposed by means of charcoal with a red heat; the acid is deprived of its oxygen, and a sulphuret of soda remains behind; its constituent parts are 23.52 of acid, 18.48 of soda, and 58 of water.

This salt is much employed in medicine; in chemistry it is applied to the decomposition of other substances, and in the arts for the extraction of soda.

Supersulphate of soda.—If the sulphate of soda be dissolved in sulphuric acid, and the solution be allowed to remain at rest, crystals are deposited which are in the form of large rhomboids; they contain an excess of acid, which is driven off with a moderate heat; they effloresce in the air, and are soluble in double their weight of water at the temperature of 60°.

Sulphite of soda.—This salt is a compound of sulphurous acid and soda, and is prepared by passing sulphurous acid gas into a saturated solution of carbonate of soda; a confused mass of small crystals is thus obtained, which being dissolved in warm water, crystallize again on cooling. The crystals are in the form of prisms, two sides of which are very broad, and two very narrow, terminated by two sided summits; and they are quite transparent.

This salt has a cool and sulphureous taste, effloresces in the air, is very soluble in water, and crystallizes again on cooling. The solution being exposed to the air, is converted into a sulphate; it readily undergoes the aqueous fusion, and if the heat be increased a portion of sulphur is driven off, and it is converted into a sulphate.

Nitrate of soda.—The compound of nitric acid and soda, formerly called *cubic nitre*, and *rhomboidal nitre*, is prepared by the direct combination of the acid and alkali, or by the decomposition of muriate or carbonate of soda by nitric acid. It crystallizes in the form of rhomboids.

The taste of this salt is cooling, but more bitter than that of nitre; it attracts moisture from the air, is soluble in three parts of cold water, and in less than its own weight of boiling water; it decrepitates on red hot coals, is less fusible than nitre, and, by decomposition, gives out oxygen and azotic gases. The constituent parts of this salt are 53 of acid, 41 of soda, and 6 of water, when dried in a temperature of 400°.

Muriate of soda.—According to the views of Sir H. Davy relative to the constitution of muriatic and oxymuriatic acid, the latter of which is a simple substance, which he has denominated *chlorine*, and the former consists of chlorine and hydrogen, this salt is not a compound of muriatic acid and soda, but of chlorine and sodium, the metallic base of soda; but whatever be its real composition, no salt has been more familiar to mankind from the earliest ages, from which it has been called *common salt*,—*sea salt*, because it is abundant in the waters of the ocean,---and *sal gem*, or rock salt, because it exists in the form of rocks or solid masses.

The greater proportion of the common salt of commerce is obtained from the waters of the ocean by evaporation with artificial heat; but in some parts of the globe, as on the shores of Spain, Portugal, and the Mediterranean; the sea water is admitted into ponds during the flowing of the tide, and its return is prevented by shutting the sluices; it is then slowly evaporated by the heat of the sun, and this process being conducted in creeks and bays of the sea, the salt is called *bay salt*.

Compounds of Soda.

But this process can only be followed in warmer and more temperate climates; in colder regions, artificial heat is generally employed in the manufacture of salt. The water is sometimes received in large ponds or flat vessels, where it evaporates in the open air; it is afterwards boiled in flat iron pans, and when the water is sufficiently concentrated, a pellicle forms on the surface, which is the crystallization of the salt; this falls to the bottom, and another pellicle is formed, till the whole of the salt is crystallized. The purity of the salt, as well as the size of the crystals, depends on slow evaporation, and hence it is, that the purest salt of this country is what is called *Sunday salt*, because it is obtained from the last quantity of water which is boiled on the Saturday night, and as it is allowed to cool slowly it evaporates gradually, and crystals of larger size and purer quality are formed.

A method of purifying common salt, proposed by Lord Dundonald, proceeds on the principle that the salts with which it is contaminated are more soluble than the muriate of soda itself. A quantity of common salt reduced to powder is put into a conical vessel or basket, which is slightly stopped at the apex, that the water may pass through, while it is placed in an inverted position; a saturated solution of common salt is then prepared, and poured boiling hot over the salt in the basket. It carries off all the more soluble salts with which it comes in contact, and, being saturated with common salt, has no effect upon it; but it must appear obvious that this is only a partial purification, because the solution cannot be brought in contact with every part of the common salt, unless the whole were dissolved.

For chemical purposes the muriate of soda must be purified by a different process. Dissolve it in four parts of cold water, filter the solution, and add to it a solution of soda, as long as any precipitate appears; evaporate the liquid, till small cubical crystals form on the surface. It may be obtained in larger crystals by slow evaporation. Common salt may be purified also by adding a solution of muriate of barytes, and then of carbonate of soda, while any precipitate is observed; the liquid is then filtered and evaporated till the solution crystallizes. By this process the earth of barytes unites with the sulphuric acid, which forms part of any compound in the solution, and the addition of carbonate of soda precipitates any of the earths which are in combination with muriatic acid.

The crystals of common salt are perfect cubes, but from this form several deviations take place; the taste is sweetish and agreeable, and is that which is properly called salt, with which similar tastes are compared. The specific gravity is 2.12. Common salt is not changed by exposure to the air. The deliquescence of the common salt of commerce is owing to its contamination with other salts; it is soluble in little more than two and a half times its weight of water, and it is almost equally soluble in hot and cold water.

Muriate of soda, subjected to a strong heat, decrepitates, and gives out its water of crystallization; melts in a red heat, and rises in white vapour; but it is unchanged, for the condensed vapour has all the properties of common salt.

Muriate of soda is decomposed by those acids which have a stronger affinity than muriatic acid for its base; by means of sulphuric acid it is decomposed for the purpose of procuring muriatic acid, and sometimes this salt is decomposed by the same acid to obtain the soda. The sulphuric acid forms sulphate of soda, while the disengaged muriatic acid is conveyed into a leaden chamber containing a solution of ammonia, where it forms sal ammoniac. The sulphate of soda, after being exposed to strong heat in a furnace, is mixed with its own weight of chalk, and half its weight of charcoal in powder; the mixture is strongly heated in a reverberatory furnace, and occasionally stirred to allow the sulphur and elastic fluids to escape; and the product is a black solid mass, composed of carbonate of soda, lime, and charcoal. More carbonate of soda may be extracted by solution in water, filtration, and evaporation.

But a process of this kind is too expensive to supply the manufacturer with this material; more economical methods, therefore, have been proposed. If common salt be mixed up with lime in the form of paste and exposed to moisture, the salt is decomposed, and an efflorescence of soda appears on the surface of the mass. The formation of soda in the soil of Egypt is accounted for on the same principle. Carbonate of lime, and muriate of soda, are abundant in the soil of that country; and wherever it is moistened with water, a copious production of carbonate of soda takes place.

With the same view of procuring the soda, common salt is decomposed by means of litharge of lead; in a mixture of four parts of litharge and one of sea salt with a little water, a decomposition of the salt is effected; the muriatic acid combines with the lead and is precipitated, and the soda remaining in the solution may be separated by filtration and evaporation.

Common salt may be decomposed also for the purpose of procuring the soda, by means of iron and other metallic substances. A plate of iron being dipped in a solution of salt, and exposed for some time to the air in a moist place, is covered with an incrustation of soda.

The constituent parts of muriate of soda, are stated at 46 of acid and 54 of soda; and considering it as a compound of chlorine and sodium, the proportions are 59.5 of chlorine and 40.5 of sodium.

In domestic economy and in many of the arts of life, no substance is of more importance than common salt; as a seasoning for food, it may be almost regarded as a necessary of life, and it is the fittest of all saline compounds for the preservation of animal matters which are intended for food. It is extensively employed in various metallurgical processes, in dyeing, and in the enamelling of stone ware.

Hyperoxymuriate or chlorate of soda.—This salt is prepared in the same manner as the compound with potash; but as the salt has nearly the same degree of solubility in water as the muriate of soda, it is difficult to obtain it in a state of purity; the crystals are in the form of square plates or rhomboids; it is soluble in three parts of cold water, and is also soluble in alcohol; it produces a cool taste in the mouth. Like the chlorate of potash, it is decomposed by means of combustible substances, as well as by acids. It melts when placed on hot coals, and gives out a yellowish light. According to the view of oxymuriatic acid being a simple substance, this salt is considered as a compound of chloric acid and soda.

Borate of soda.—This salt is a compound of boracic acid and soda, which is formed by saturating the acid with the alkali; but little seems to be known of its nature and properties.

Sub-borate of soda, or borax.—The ancients, it is supposed, were acquainted with this saline compound; and it was called *chrysocolla*, from its property of soldering gold and other metals. The word borax is derived from some of the Eastern languages. It was only in the beginning of the 18th century that the acid was separated from the alkali by Homberg, and it was long known under the name of *the sedative salt of Homberg.* Borax is a natural production of the earth in many parts of the world, and particularly of eastern countries. In India it is called *tincal*; and when it is brought into commerce it is distinguished by the name of crude borax. In this state it is in the form of small greenish crystals, intermixed with a greasy matter.

The purification of borax was originally in the hands of the Venetians; it was afterwards exclusively practised by the Dutch, and more lately has been conducted in this country. The repeated solutions and crystallizations which are found requisite, are performed in leaden vessels; and in one part of the process it is supposed lime-water is employed.

Purified borax is in the form of six-sided prisms, two sides of which are broader, terminated by three-sided pyramids; the taste is sweetish and alkaline; it changes vegetable blues to green, effloresces slightly in the air; and 12 parts of cold water and 6 parts at the boiling temperature, dissolve one of borax.

Borax melts with heat, assumes the form of a porous mass, and is converted into calcined borax; when the temperature is raised to a red heat it becomes a transparent glass, soluble in water.

As the name imports, the alkali is in excess in this compound, and its constituent parts are 34 of acid, 17 of soda, and 49 of water.

Borax is much employed as a flux for metals, and to promote the soldering of the more precious metals; it is used also as a flux for minerals, treated by the blow-pipe; and calcined borax is applied to eruptions of the mouth as an absorbent.

Phosphate of soda.—This compound of phosphoric acid and soda, was formerly known by the name of fusible or *microcosmic salt.* It is obtained by saturating, with carbonate of soda, the liquid acid phosphate, which is extracted from burnt bones by means of sulphuric acid. The alkali must be added in excess; and as the carbonate and a little phosphate of lime are precipitated in the solution, it requires to be filtered and evaporated till a thin pellicle appears on the surface, when it crystallizes by cooling.

The crystals are in the form of lengthened rhomboids, or of rhomboidal prisms; the taste is cooling and sweetish; it effloresces in the air; and four parts of water at 60°, and one-half of its weight of boiling water, are sufficient for its solution.

Exposed to heat it undergoes the watery fusion; melts in a red heat, and on cooling is changed into a white glass; and, under the action of the blow-pipe on charcoal, becomes opaque on cooling, and assumes a polyhedral form. By means of sulphuric, nitric, and muriatic acids, it is partially decomposed, and is converted into the superphosphate of soda. The constituent parts of this salt are stated at 20 of acid, 18 of alkali, and 62 of water; and it is much employed in medicine as a mild laxative.

Carbonate of soda.—This is the saline compound which is extracted from sea plants, especially from the fuci. The carbonate may be prepared by dissolving a quantity of the soda of commerce, in three or four times its weight of pure cold water, and then by filtering the liquid and evaporating till a slight pellicle is formed. This pellicle, which consists of small cubes of common salt, is to be removed, and the heat continued as long as any pellicle appears; after which the liquid is set aside to cool, and the carbonate of soda crystallizes.

The crystals are in the form of rhomboidal octohedrons, formed by two four-sided pyramids, truncated near the base; the taste is slightly acrid; it converts vegetable blues to green, effloresces speedily in the air, and is soluble in two parts of cold, and little more than its own weight of boiling water.

Exposed to heat it undergoes the watery fusion, melts in a red heat, and is converted into a transparent liquid. The constituent parts are 16 of acid, 22 of base, and 62 of water.

Supercarbonate of soda.—This compound, in which the acid is in double the proportion in which it exists in the carbonate, may be prepared by passing a current of carbonic acid gas into a solution of common carbonate of soda; a solid mass is deposited. This salt has been found native in some parts of Africa, and is so little changed by exposure to the air, that the walls of edifices are constructed of it in place of stone.

Arseniate of soda.—This compound of arsenic acid with soda, resembles the arseniate of potash in many of its properties. When the acid and alkali are saturated, it affords crystals in the form of six-sided prisms; but, with an excess of acid, it is deliquescent, and does not crystallize.

Acetate of soda.—The compound of acetic acid and soda, formerly known by the name of *crystallized foliated earth*, is prepared by saturating the acid and the alkali, filtering the solution, evaporating till a pellicle appear on the surface, and setting it aside to form crystals.

This salt crystallizes in the form of striated prisms like Glauber's salt; has a bitter pungent taste; is soluble in three parts of cold water, is decomposed by heat; and the residue, after distillation, has a phosphorescent property.

Oxalate of soda.—If two parts of crystallized carbonate of soda be dissolved in one part of oxalic acid, part of the oxalate of soda is precipitated, and part remains in the solution; which being evaporated affords crystals in small grains. This salt gives a green colour to the syrup of violets. Oxalic acid also forms an acidulous salt with soda.

Tartrate of soda.—Tartaric acid, saturated with soda, yields crystals in the form of fine needles; this salt combines with another portion of acid, and forms a supertartrate, which is less soluble in water.

Citrate of soda.—Citric acid and soda afford a salt which crystallizes in six-sided prisms; has a saline taste, effloresces in the air, and is soluble in two parts of water; when it is heated it froths up, and is converted into charcoal.

Benzoate of soda.—Benzoic acid and soda form a salt which readily crystallizes, has a sharp and saline taste, is deliquescent in the air, and very soluble in water.

Camphorate of soda.—A solution of carbonate of soda being saturated with camphoric acid, after evaporation with a moderate heat and cooling, yields crystals which are white and transparent, and not very regular. The taste of this salt is bitter; it effloresces in the air; is soluble in eight parts of boiling water; with heat it swells up; the acid is dissipated in thick aromatic vapours; and it burns with a blue flame. Under the blow-pipe the acid is sublimed, and the alkali remains behind.

Sect. III. *Ammonia and its Combinations.*

Ammonia is well known in familiar language, under the names of hartshorn, spirit of hartshorn, volatile alkali, and volatile spirit of sal-ammoniac. The name ammonia is derived from sal-ammoniac, a salt collected in the vicinity of the temple of Jupiter Ammon in Africa, which was frequented by camels and other animals in the train of those who visited the temple. Ammonia seems to have been first described by some of the alchemists in the 15th century; but it was not till towards the close of the 18th century that it was discovered to be a compound of hydrogen and azote, and its properties were fully investigated.

Preparation.—Three parts of quicklime and one part of sal-ammoniac in powder, being put into a retort, the beak of which is immersed under mercury, and a jar filled with mercury inverted above it, and heat being applied, a gas comes over in great abundance. This gas is ammonia or ammoniacal gas; sal-ammoniac is a compound of muriatic acid, and ammonia, and the lime having a stronger affinity than the ammonia for the muriatic acid, combines with it, and the ammonia being set free passes off in the state of elastic fluid.

Properties.—In its physical properties ammoniacal gas resembles common air; it is transparent and colourless, the smell is extremely pungent, and the taste acrid and caustic, but less corrosive than the other alkalies; 100 cubic inches weigh about 18 grains; it changes vegetable blues to green. It is

Compounds of Ammonia.

unfit for respiration and for the support of combustion.

When exposed to strong heat, as when it is passed through a red hot porcelain tube, it is decomposed, and converted into azotic and hydrogen gases; when the temperature is reduced to 45° below 0° it is condensed, and assumes a liquid form; but when the temperature is elevated it is restored to the state of elastic fluid.

The constituent parts of ammonia, it has been already stated, are hydrogen and azote, and the proportions of these elements in the gas are three volumes of hydrogen and one volume of azotic gas diminished to two volumes. These proportions have been obtained by the decomposition of dry ammoniacal gas by means of electricity.

Ammoniacal gas is rapidly absorbed by water. At the temperature of 50°, and when the barometer is nearly 30, water combines with 670 times its bulk of the gas; the specific gravity of the water is diminished. This solution is called liquid ammonia, and when it is exposed to the temperature of 130° the ammonia is driven off in the gaseous form: and when gradually cooled to 35° or 40° below 0° it crystallizes, and is then destitute of smell. When ammoniacal gas combines with water the latter becomes warm in consequence of the caloric which is given out by the gas as it combines with the liquid. The specific gravity of the water is always diminished by its combination with ammoniacal gas; but it varies with the different proportions of the gas, and the boiling point of the liquid is subject to similar variations.

Different products are obtained when ammoniacal gas and oxygen gas are inflamed by electricity, or are passed through a red hot porcelain tube, according to the proportions of the two gases employed. When the oxygen gas is in greater proportion the whole of the ammonia disappears, and nitrate of ammonia is deposited. Here part of the oxygen combines with part of the azote of the ammonia to form nitric acid, and another portion of the oxygen uniting with part of the hydrogen of the ammonia forms water, and the whole enters into the composition of the nitrate of ammonia. But when the ammonia is in excess it is entirely decomposed, a portion of its hydrogen forms water with the oxygen, and another portion is mixed with the azotic gas, which is set free.

Ammoniacal gas mixed with chlorine gas burns with a white flame, the ammonia is partially decomposed, the hydrogen of which uniting with the chlorine forms muriatic acid, and the latter entering into combination with the remaining ammonia forms sal-ammoniac; a portion of azotic gas remains behind.

Ammoniacal gas is absorbed by charcoal in the cold, without any change of its properties; but when it is passed over red hot charcoal it is decomposed; part of the carbone of the charcoal combines with the ammonia, or with its elements, and forms prussic acid.

Sulphuret of ammonia.—In the state of vapour, ammonia combines with sulphur, and forms a sulphuret, which, like the other sulphurets of the alkalies, possess the property of decomposing water and entering into new combinations.

Hydrosulphuret of ammonia.—If a current of sulphuretted hydrogen gas be passed through liquid ammonia, the solution becomes of a greenish-yellow colour, and is converted into the hydro sulphuret of ammonia. If equal parts of sal-ammoniac, lime and sulphur be distilled in a retort, a liquid of a deep orange colour is obtained; it exhales extremely fœtid vapours, in consequence, it is supposed, of retaining an excess of ammonia; and it was formerly called the *fuming liquor of Boyle.* When the fumes have passed off the excess of sulphur is deposited, and the hydrosulphuret remains behind in a state of purity. The hydrosulphuret of ammonia may be also prepared by combining sulphuretted hydrogen gas and ammoniacal gas together, and condensing them in a bottle kept cool by means of ice. It crystallizes in the form of needles, is transparent and colourless, and from its extreme volatility is sublimed at the top of the vessel in which it is kept.

Hydroguretted sulphuret of ammonia.—If hydrosulphuret of ammonia be poured on sulphur, it combines with a portion of the sulphur, and is converted into the hydroguretted sulphuret. The same compound may be obtained by separating the last portion of the liquid which comes over in the distillation of the fuming liquor of Boyle.

Sulphate of ammonia.—The compound of sulphuric acid and ammonia may be prepared by saturating the acid and alkali and afterwards crystallizing it. It was formerly called *secret sal-ammoniac* of Glauber, because it was discovered by that chemist.

The crystals of this salt are in the form of six-sided prisms, with unequal sides, terminated by six-sided pyramids; excepting in moist air it undergoes little change, is soluble in two parts of cold water, and in a smaller proportion of boiling water; melts with heat, and if the heat be continued is deprived of part of its base, and becomes a supersulphate, which reddens vegetable blues, and is more soluble. The constituent parts are 55 of acid, 15 of ammonia, and 30 of water.

Sulphite of ammonia.—This salt is formed by passing a current of sulphurous acid gas into a vessel of liquid ammonia. The solution being saturated, affords crystals on cooling.

The form of the crystals is similar to the sulphate, or in four-sided rhomboidal prisms, terminated by three-sided summits. This salt has a cool, pungent, and sulphureous taste; deliquesces in the air, and is converted into the sulphate; is soluble in its own weight of cold water, and a saturated solution, agitated in the open air, is, in a few hours, converted into the sulphate. The constituent parts are 60 of sulphurous acid, 29 of ammonia, and 11 of water.

Nitrate of ammonia.—The compound of nitric acid and ammonia is prepared by the direct combination of the acid and alkali, and is obtained in crystals by evaporation and slow cooling. It was formerly called *nitrous sal-ammoniac,* and *inflammable nitre.* It crystallizes in six-sided prisms; but the forms of the crystals vary with the temperature in which the evaporation goes on. The taste is acrid and bitter; it is deliquescent in the air; is soluble in two parts of cold water, and boiling water dissolves double of its own weight.

Nitrate of ammonia readily undergoes the watery fusion, is entirely deprived of its water of crystallization, and when the temperature is increased it explodes with the evolution of a brilliant white flame. The constituent parts of this salt afford an explanation of this rapid combustion. The hydrogen of the ammonia unites with the oxygen of the acid, water is formed, and the azote, the other element of both the acid and alkali, is disengaged, and appears in the form of azotic gas.

Nitrous oxide, which is a compound of azote and oxygen, is obtained from the decomposition of this salt; and it appears, from experiment, that in the different states of the crystallization of the salt, it requires different degrees of heat for its fusion and decomposition; but, in general, the dry nitrate of ammonia undergoes rapid decomposition between the temperature of 340° and 480°, and the prismatic and fibrous nitrates are decomposed at temperatures above 450. In preparing the nitrous oxide, or gas of paradise, for the purpose of being inhaled, it is necessary to attend to the temperature at which the salt is decomposed.

A singular explosive substance is obtained in the decomposition of nitrate of ammonia by means of chlorine. If a twelve ounce phial, filled with chlorine, be inverted over a weak solution of nitrate of ammonia at the temperature of 110°, the gas is absorbed, as appears from the solution rising in the bottle, and an oily matter is formed and falls to the bottom. This substance was first observed in France, and has been particularly examined by the chemists of this country. The colour approaches nearly to that of olive oil; the smell is extremely penetrating, and it is more volatile than ether. Under water, at the temperature of 200°, it is not decomposed, but at 212° it explodes with great violence. It produces also violent detonations when in contact with inflammable substances, as oil of almonds or phosphorus.

The water which is in contact with this substance freezes at the temperature of 40°, but the substance itself still retains its fluidity, and indeed continues liquid when subjected to very great cold. When kept in water it undergoes decomposition, and azotic gas is given out. It is decomposed also by muriatic acid; chlorine is disengaged, and muriate of ammonia remains in the solution.

In making experiments with this remarkable compound, the precaution should be strictly attended to of never employing more than a single grain, at least by the inexperienced. The constituents of this substance, which is denominated *chloride of azote*, are 19 of azotic gas and 81 of chlorine by bulk.

Muriate of ammonia.—The name of *sal-ammoniac* has been long familiar in chemistry and the arts. It is derived from Ammonia, a country of Lybia, and the name, which is derived from the Greek, and signifies *sand*, is descriptive of the soil of that region, where a temple was erected to Jupiter, who was also distinguished by the title of Ammon. The same salt seems to be a production of volcanoes, in the crater of which it is found sublimed; and the waters of some lakes in Tuscany hold it in solution.

The muriate of ammonia, as it is found in nature, is very impure; and therefore it is subjected to various processes to separate the foreign ingredients. In Egypt the animal matters which are impregnated with this salt are collected and burned in furnaces constructed for the purpose, and sometimes they are used as the common materials of fuel. The soot thus formed is said to be introduced into large glass bottles and exposed to a strong heat, which is gradually increased for three days, at the end of which the salt is sublimed in the form of a cake at the upper part of the bottles.

In the European manufactories this salt is prepared by different processes. The ammonia is extracted from soot or from animal matters, and with the addition of sulphuric acid is converted into sulphate of ammonia, which being mixed with common salt or muriate of magnesia, a double decomposition is effected, the sulphuric acid uniting with the soda or magnesia, and the muriatic acid combining with the ammonia. The different degrees of solubility of the new compounds afford the manufacturer an opportunity of separating them. The sulphate of soda or of magnesia is evaporated and crystallized in leaden vessels; and the muriate of ammonia, while in the state of a soft mass is put into large bottles and sublimed in the form of a cake at the upper part of the vessel.

Prepared by the process of sublimation, the muriate of ammonia is in the form of a solid mass, which has a slight degree of elasticity, yields to the pressure of the finger, and is with difficulty reduced to powder. The specific gravity is 1.4; the taste pungent and cooling. It is soluble in three or four times its weight of water, in which it crystallizes by slow evaporation in the form of long four-sided pyramids; but when the crystals are small, and the crystallization confused by rapid evaporation, the crystals exhibit a feathery appearance. Great cold is produced during its solution in water.

It is scarcely altered by exposure to the air, when it has been prepared by sublimation; but the crystals are deliquescent. It is fusible and volatile by heat; thrown on red hot coals, it rises in white vapour, and is entirely dissipated; and with a higher temperature it undergoes decomposition,

Muriate of ammonia is decomposed by sulphuric acid; the muriatic acid is separated with violent effervescence; and by the action of nitric acid a nitro-muriatic acid is prepared.

The constituent parts of this salt are 68 of acid, and 32 of ammonia. It is of great importance in dyeing, in the preparation of colours, in metallurgy, and some other arts; so that it is a valuable object of manufacture and commerce.

Hyperoxymuriate or chlorate of ammonia.—This saline compound is prepared by mixing carbonate of ammonia with a solution of any of the earthy chlorates, or by direct combination of the two constituents. It crystallizes in the form of fine needles; is very soluble in water and alcohol; is very volatile, has a sharp taste, and is decomposed by strong heat.

Phosphate of ammonia.—This salt was formerly

Compounds of Ammonia.

known by the names of *fusible and microcosmic salt.* It may be prepared by direct combination of phosphoric acid and ammonia. By slow evaporation of the solution to a proper consistence, crystals are obtained when it cools; but it is only by spontaneous evaporation that it crystallizes in regular forms, which are octohedrons, or four-sided prisms, terminated by four-sided pyramids, and oftener a confused mass of small needles. The taste is cooling and pungent; it changes the syrup of violets to green, and the specific gravity is 1.8.

This salt is slightly deliquescent in the air; is soluble in twice its weight of cold water, when heated undergoes the watery fusion, and melts into a transparent glass, which is acid in consequence of part of the base being dissipated. It is readily decomposed by charcoal and the stronger acids, as well as by the fixed alkalies.

The phosphate of ammonia is conveniently employed as a flux with the blow-pipe, in assaying mineral substances, and it is much used in the fabrication of coloured glasses, and in the artificial imitations of precious stones.

Phosphite of ammonia.—The compound of phosphorous acid and ammonia is prepared by direct combination of the acid and alkali; and by slow evaporation crystals are obtained, although it crystallizes with some difficulty, in the form of long transparent needles.

This salt is slightly deliquescent in the air, and is very soluble in water. Heated on charcoal under the blowpipe, it is first deprived of its water of crystallization, and is then surrounded with a fine phosphoric light; after which, when vitrification commences, bubbles of phosphuretted hydrogen gas are evolved, which explode when they come in contact with the air. The phosphoric acid remains after the decomposition.

Carbonate of ammonia.—The saline compound of carbonic acid and ammonia is well known under the name of *concrete volatile alkali.* It was formerly procured by the distillation of animal substances, and particularly horn, as the horns of the hart, from which it was called hartshorn. It is easily procured by mixing together two parts of chalk with one part of sal ammoniac, both well dried, and reduced to powder, and exposing them to heat in a retort. The muriate of ammonia is decomposed; the muriatic acid combines with the lime and remains in the retort, and the ammonia, uniting with the carbonic acid of the chalk, is sublimed in the form of a white crystallized mass. The carbonate of ammonia is collected in a proper vessel, which is kept cool with wet cloths.

The carbonate of ammonia crystallizes, but the crystals are small and irregular; the taste is slightly acrid, and the smell similar to ammonia, but weaker. It converts vegetable blues to green.

When it is pure, carbonate of ammonia is not perceptibly changed by exposure to the air; two parts of cold water dissolve more than one of the salt, and water, at the temperature of 120°, dissolves more than its own weight. Boiling water drives it off in the state of vapour, so that it cannot be employed for its solution.

Supercarbonate of ammonia.—The common carbonate of ammonia, dissolved in water, and exposed to the action of carbonic acid gas, combines with a larger proportion, and, by evaporation of the solution, crystallizes in the form of small six-sided prisms. In this state the salt is destitute of smell, and it has less taste.

Compounds of Ammonia.

Acetate of ammonia.—The compound of acetic acid and ammonia has been long known under the name of *spiritus mindereri*, in which state it is combined with an excess of acid. It may be prepared by saturating the acid and the alkali with each other, which can only be done when they are both in a state of concentration. The volatility of the compound renders the crystallization difficult, excepting by slow evaporation or sublimation, and then the crystals are long, slender, and flattened, pointed, and of a pearly white colour. The taste is cooling, with a mixture of sweet. This salt is deliquescent in the air, and very soluble in water.

Acetate of ammonia melts at 170°, and is sublimed at 250°. By distillation of the salt in solution with a strong heat, it undergoes partial decomposition. The ammonia rises first, then the acid, and, at the end of the process, part of the salt itself.

Oxalate of ammonia.—A compound of oxalic acid and ammonia is prepared by direct combination of the acid and alkali; the salt crystallizes after evaporation. When the acid is saturated with the alkali, the crystals are in the form of four-sided prisms, terminated by two-sided summits, one of which includes three sides of the prism; the taste is bitterish; one part of the salt is soluble in 20 parts of water, and it is insoluble in alcohol.

When oxalate of ammonia is exposed to heat, carbonate of ammonia is driven off, and nothing remains behind but a little charcoal. This salt is also decomposed by the mineral acids. With oxalic acid a new compound is formed, which is a superoxalate of ammonia; and the oxalates of potash and soda form compounds with this salt, which are distinguished by the name of *triple salts.*

Oxalate of ammonia is much employed as a reagent in detecting lime in liquid solutions, and it answers the purpose well of ascertaining the nature and proportions of calcareous salts.

Tartrate of ammonia.—The compound of tartaric acid and ammonia yields a salt which readily crystallizes, has a cooling bitter taste, is very soluble in water, and easily decomposed by heat. By the action of the stronger acids part of the base is separated, and a supertartrate of ammonia, which is less soluble in water, is formed.

Camphorate of ammonia.—This salt is prepared by adding camphoric acid to a solution of carbonate of ammonia in hot water, till the effervescence ceases. The evaporation must be conducted with a very moderate heat, on account of the volatility of the ammonia. This salt is not easily crystallized; when the solution is not too much evaporated it affords a crystalline mass, in which small needles appear; but when it is evaporated to dryness, a solid opaque mass, with a slightly bitter and pungent taste remains.
